LONDON :  
PRINTED AT THE JOURNAL OF HORTICULTURE OFFICE,  
171, FLEET STREET.

## TO OUR READERS.

---

SIXTY-FIVE volumes of the *Cottage Gardener* and the *Journal of Horticulture* are before us as we write, and they form, we think, an encyclopædia of practical gardening which all, from the humblest tiller of the soil to the most accomplished cultivator, may peruse with advantage. They represent the thought and labour of a band of skilled and earnest co-workers, some of whom have long since rested from their labours, and have left behind them cherished memories; others, old and trusted, still remain worthy exponents and sound teachers of the art of gardening, while recruits of high promise are ever joining our ranks.

That great concentration of effort cannot but have had a beneficial influence in improving the gardens and gardening of our land. This has been the object which has been steadily kept in view throughout the work, and it remains the object of our continued exertions.

The founder of this Journal wrote on its first page, "No one values the services of science more highly than we do. We know that it points out and illumines the path of the gardener; it aids and sustains him in his progress along that path, but the path itself is Practice. Upon this we shall place our foundation."

That foundation has proved sound, and the results have been such that might tempt us to boast; but as boasting is born of vanity we refrain.

The address to the readers of the *Cottage Gardener* at the close of the first year of its publication are equally applicable now and appropriate—"Like the pilgrim of old, we are grateful for the past and hopeful of the future—grateful because we know we have achieved a measure of good by improving the gardening, and by bringing pleasure and comfort around many British homes; hopeful because our sphere of usefulness widens as we go, and because the materials and the aid for effecting our purposes increase around us as we advance."

He who penned those lines upwards of three decades ago happily remains with us enjoying his well-earned repose; and many readers will be glad to see his portrait in the first number of the sixty-sixth half-yearly volume of the work that he commenced, and for which he did so much towards bringing to its present established state of prosperity.

## INDEX.

—0—

- ABRONTA LATIFOLIA, 378  
 Abutilons, culture of, 524  
 Aechimenes for late flowering, 269; from cuttings, 328  
 Actinopteris radiata australis, 254  
 Adiantums, repotting, soil for, 99; Bausei, 471  
 Adonises, species of, 393  
 Advertisement, extraordinary, 9  
 Aecidium grossularia, 531  
 Agave Parryi and Hunti, 375, 531  
 Agra, Taj Gardens at, 511, 534  
 Agriculture, primitive, 531  
 Alexandra Palace Floral Exhibition, 418, 482  
 Alexander, death of Mr. James, sen., 211, 233  
 Aloe unhealthy, 56; Lynchi, 173  
 Alternanthera paronychioides aurea, 241  
 Amaranth, Globe, culture, 261  
 Amaryllises, John Heal, Royal Standard, Miss Alice Gair, 194; Mr. Henry Little, 231; Storr's Beauty, Mad. Albani, Empress of India, Cecilia, 254  
 Amaryllis culture, 159  
 Amateurs, notes on plants for, 513  
 American forests, 74  
 Anemone japonica alba for pots, 369  
 Angraecums, notes on species, 154, 189; A. citratum, 155  
 Ansellia africana, 65  
 Ants, extirpating, 386  
 Antwerp International Show prizes, 396  
 Annuals, sowing, 220; for exhibition, 392; a plea for, 330; distasteful to slugs, 345; for spring, 414; for bouquets, 465  
 Apple — American trade, 113; Canadian, import of, 29; culture, with corn, 1; for succession, 179; King of the Pippins, 24; Queen, 30; frozen, 78; Northern Spy, 495; crop in Massachusetts, 510  
 Apple trees, planting in fields, 149; pruning dwarf 365; on Plum stock, 456  
 Aquilegia formosa, 400; Stuartii, 490  
 Aralia Kerchoviana, 336  
 Araucaria Bidwilli in Queensland, 49  
 Aristolochia Goldiana, 396; at Regent's Park, 464  
 Aromia mosehata, the Musk Beetle, 271  
 Asparagus — beds, forming, 343; Early Purple Argenteuil, 42; green v. blanched, 415; prizes for, 90, 398; removing, 139; soil for, 56; A. tenuissimus, 336; beetle destroying, 449; awards of prizes for, 472; cutting, 475  
 Asplenium Baptistii, 194; A. cicutarium, 131; A. Saundersoni, 254  
 Astelma eximium, 233  
 Aster argophyllus, 321  
 Asters, culture of, 372; gymnocephalus, 409  
 Astilbe Thunbergii, 422  
 Auriculas, autumn flowering, 2, 42; v. aphids, 209, 251; "D. Deal's," experience, 209; v. frost, 135; in Yorkshire, 280; Mr. Horner's lecture on, 397, 338; Southern Show of, 315; Northern Show of, 332; A. purpurea, Splendour, Mrs. Moore, 336; Mrs. Wm. Brown, Philip Frost, John Ball, Milda, Lizzie, 375; classification, mealed centres, 399; Show, notes on, 382; at Shubden Head, new varieties, 438; at Warrington (Mr. Bolton's), 481  
 Australian plants in India, 337  
 Azaleas, seedlings, 159; Mrs. Gerard Leigh, 192; Roi Leopold alba, 254; Madeleine, 383  
 BALSAM CULTURE, 327  
 Bamboos in Japan, 49  
 Barnet Nurseries, 289  
 Bath and West of England Show, 471  
 Beans, Broad and Kidney, new varieties of, 43; Kidney, forcing in boxes, 274; dwarf runners, 314  
 BEES —  
 The progress of bee-keeping, 14; Congress at Cologne, 15, 34; brandy for, 33, 54; Association's meeting, 36; in Ireland, Dorset Bee-keepers' Association, 54; Ligurians in New Zealand 55; buzzing in winter, 56; the challenge, past and present, 76; hive entrances, 77, 78; hives, which best for profit, 97; packing for long voyages, sponges in hives, 98; Congress at Cologne, foul brood, "Handy Book of Bees," 117; examining stocks, wooden v. straw hives, crude and perfect honey, 138, 157; Stewarton hive management, 140; annual meeting of Bee-keepers' Association, cheap bar-frame hives for cottagers, 157; the Stewarton hive, aparian operations in March, 178; seasonable hints, 197; expansible hives — profitable mode of using, 197; a German apiary, 198; moulded combs, dead bees, 199; the straw hive, 217; the Heath and Caucasian bee, 218; makers of hives, removing bees, placing stocks in new hives, 220; British Bee-keepers' Association's Conversazione, Mr. Lyon's hive, Mr. Cheshire's experiments on hive sides and temperature, 239; introduction of bees to Ceylon, in Cyprus, 240; bees and snow, modes of feeding, giving foundation, 242; Armagh Bee-keepers' Association, 244; a retrospect, 259; "American Bee Journal," fertilisation in confinement, 260; aparian work in April, in Ceylon, importation of Cyprians to India, 279; v. nut-tree pollen, fertilisation in confinement, adulteration of honey with glucose, 300; introducing queen, preventing swarming, Apis dorsata, 320; how, when, and where to use comb foundation, 343; successful shipment of humble bees to New Zealand, 344; using comb foundation, 363; Indian bees, Apis dorsata, notes on species in Ceylon, 364; remedies for strings, 366; prizes at Tunbridge Wells, 368; building in the open air, 384; aparian calendar, 385; removing stocks, arranging an apiary, 406; Irish cottager's hive, 407; cork-packed hives, feeding bees with honey, section boxes, foul brood, space in hives, handling bees, "doubling," 408; artificial swarming before drones appear, casting, building drone comb, over-swarming, 427; combs between frame and hive, evidence of  
 BEES — Continued  
 queen, extractor, and heather honey, 428; moths in hive, 430; securing straw or wild colonies, 447; queen rearing from nuclei, 448; fertile workers, clearing off combs, empty queen cells, expelling drones, abolishing an old skep, 450; notes on swarming, 473; driving *in situ*, 474; artificial swarming, 493, 494; "The Stewarton Hive," (review), bitter honey, 494; bees poisoned by Digitalis, 495; removing super, uniting bees, 496; prizes for honey at Tunbridge Wells, 498; search for Apis dorsata, 515; making most of stock in straw hives, 517; supers and prevention of swarming, 519; authorship of "Modern Bee-keeping," 538; increasing stocks, 539; melliferous plants, 539; removing sections, 541; Ipswich Aparian Show, 542  
 Bedding plants, notes on, 363  
 Begonia socotrana, 48; potting Tuberosa Begonias, 99; B. Nealtalia for rooms, 186; at Forest Hill, 526  
 Belladonna and Guernsey Lilies not flowering, 261  
 Benbow, death of Mr., 378  
 Beetles, meal and cellar, 47; the Colorado in Devonshire, 142  
 Biennials, raising from seed, 429  
 Birch bark, new product from, 415  
 Birds, arrival of migratory, 304; v. fruits, 550; utility of in gardens, 382; wings of, 452  
 Birmingham Spring Show, 310  
 Blackbeetles, a plague of, 524  
 Blood manure, making, 158  
 Boilers and heating, notes on, 172, 209, 220; valves, management of, 281  
 Books, review of — "Art of Gardening," 236; "Botany for Elementary Students," 70; "Carters' Practical Gardener," 236; "Cherry and Medlar," Mr. Fish's work, 397; "Fields of Great Britain," 237; "Improved Pruning and Training of Fruit Trees, or Extension v. Restriction," 333; "Practical Fisherman," 388; "Ladies' Miltum in Parvo Gardening," "Epitome of Gardening," "Horticultural Buildings," 409; "Rosarians' Year Book," 49; "Manual of Coniferæ," 325; "Our Kitchen Garden," 237; "School Garden," 237  
 Bone meal, uses of, 281  
 Border, planting ribbon, 118  
 Botanic (Royal) Society's Show fixtures, 70; first spring Show, 254, second Spring Show, 341; first summer Show, 425  
 Bougainvillea spectabilis, 360  
 Bouquet, attractive, 397  
 Bouvardias, notes on, 317; double, Alfred Neuner, 417, 528  
 Box-edging, transplanting, 179  
 Boxes for Dahlias and Pansies, 365, 386  
 Broccoli, Ledsham's White, 16; for succession, 35; v. Cauliflowers, 302; for succession, 322; in firm ground, 394; for succession, 503, 504 raising and planting, 523, 528  
 Brugmansias, notes on, 377  
 Brussels Show schedule, 274  
 Buckland, the late Mr., proposed memorial to, 304  
 Bulbs frozen, 48; at Duncevan, 335  
 Butter Nuts, 99  
 CABBAGE — plants clubbing, 139; Kerguelin's, 441  
 Cacalia articulata, 16  
 Cactuses, culture of, 35; hardy forms of, 480  
 Caladium, Frederick Bause, 375; C. candidum, C. Mithridate, C. J. R. Box, 488  
 Calanthe, Sandhurstiana at Chelsea, 113; at Drumlanrig, 215  
 Calceolarias at Bedford Hill House, 420; at Reading, 421; Cloth of Gold, 422  
 Caledonian (Royal) Society's Spring Show, 292  
 Camellias not expanding, 35, 78; raising from seed, 199; at Waltham Cross, select varieties, 270; fragrant, 487  
 Campanula persicifolia alba, 442  
 Canna iridiflora var. Ehemanni, 193  
 Candollea cuneiformis, 87  
 Cardiff Rose Society, 294  
 Carnations for winter, 35; Andalusia, 26, 64; culture of perpetual at Longleat, 225; Belle Rose, 314; old varieties and properties of, 449; layering, 449; Lady Musgrave, 483  
 Carrington Moss, improvement of, 191  
 Camassia esculenta, 569  
 Carpet beds, references to designs for, 280, 335, 426, 440; references to plans, 449  
 Caryocar nuciferum, 99  
 Casuarinas in Australia, 113  
 Caterpillar (Gooseberry) and Currant grub, notes on, 188, 208, 418; food for rooks, 465; plague of in Surrey, 480; on Holly shoots, 518  
 Cauliflower, Henderson's Wellington, 43; varieties and periods of sowing, 86; sowing for succession, 118; early, 177; and Broccoli, 534  
 Celery, pithy, 48, 68, 112; Cole's Solid Red, 68  
 Cereus Fendleri, 130; flagelliformis, culture, 261  
 Chamaejasme graminis, 518  
 Cheiranthus alpinus, 444  
 Chelsea, a visit to, 332  
 Cherries, double-blossomed, 401; Morellos as standards, 464; gumming of and remedy, 475; Morello, failing, 540  
 Chionodoxa Lucilia, 249  
 Chiswick in May 352; notes from, 528  
 Chlorophyll, 167  
 Chorozema cordatum splendens, 229, 274  
 Chrysanthemums for country gardens, 44; Society, Northampton, testimonial to Secretary, 70; Ethel, 130; potting, 294; good summer-flowering, 319  
 Chrysomela populi, larva of, 403  
 Cinchona consumption, 195  
 Cinerarias, William Jennings Master Colvin, 114; culture of, 168; Mr. H. Little, 194; notes on double, 211; at Red-lee, 232; "Marched Past," 336; raising seedlings, 475  
 Cladrasia amurensis, 400  
 Clarkias, autumn-sown, 331  
 Clematises — culture in pots, propagation, 349; good varieties, 350; ethusifolia var. latifolia, 378; W. E. Gladstone, Lady Constance Kennedy, George Elliot, 422; in pots, 441; montana, 443  
 Clerodendrons, culture of, 538  
 Climbers for trellis, in boxes, 98; hardy, pruning and planting, 177, 217  
 Cockseomb culture, 209  
 Cocoa-nut fibre refuse, references to uses of, 261  
 Cœlogyne cristata alba, 254  
 Coffee leaf disease, 153  
 Coleus, Miss Simpson, C. Mrs. Stedall, 488  
 Columbines, notes on hybrids, 502  
 Comparettias, notes on, C. falcata, 107  
 Compass Plant, 113  
 Composts, fibreless for potting, 287  
 Communications, 56  
 Conifers, transplanting, 365; at Woodstock, Kilkenny, 530  
 Correa cardinalis, 127  
 Cottage gardening, 30, 75, 110, 535  
 Crassula jasminea, 443, 479  
 Crawfordia luteo-viridis, 378  
 Crickets, destroying, 507  
 Crinum Forbesianum, 378  
 Cricocerus Asparagi, 310  
 Crocuses, species at Chiswick, 207; versicolor, 241  
 Croton Lady Zetland, 375, 505; C. Hawkeri, 381  
 Crops, notes on rotation of, 145; arrangements for, 145  
 Crystal Palace school of gardening, 272; flowers at, 312  
 Crystal Palace Show, 444  
 Cucumber, the Cardiff Castle, 29, 52; and Melons in houses, 99; raising plants, 118, 180; extensive culture, 173; Mr. Whittaker's large house for, 250, 329; cultural notes, 258; planting in frames, 390; pruning and management, 318; affixing wires for, 321; Howe's Challenger, 417; disease, reference to, 518  
 Currants, black, renovating, 345 profits from, 358  
 Cycads at Kew, 396  
 Cyclamens, Reading Gem, 70; Lilian Cox, Charming Bride, 194; Ruby Gem, 231, 254; culture of, 233; Queen Victoria, 254  
 Cydonia japonica alba in pots, 65  
 Cyperus laxus variegatus, 375  
 Cypripedium insigne for cutting, 48; purpuratum, 65; C. Stonei var. platyantum, high price of, 379; selligernum majus, 488  
 DAHLIAS — culture of and varieties, 185  
 Dai-kon, 486  
 Daisies, culture of double, 407  
 Dalechampia Rocchiana rosea, 134  
 Daphne indica in Cornwall, 133; Fioniana, 356  
 Davallia elegans polydaetyla, 336  
 Delphiniums, choice varieties, 319  
 Dendrobium Hilli, 133; Kingianum, 207; Itidiorum var. candidum, 231; Wardianum, 317; crassinode, 337; D. Picardi, D. cucullatum, D. Bensoniae, D. nodatum, 338  
 Dendrochilum glutaceum, 113  
 Disbudding, 371  
 Diphyllia cymosa, 487  
 Dominy, Mr., proposed testimonial to, 439  
 Dracena Lindenii, Rossi, Recurva, 375  
 Droseras, culture of and species, 4  
 Drumlanrig, in winter, 165, 209  
 Ducks for profit, 286  
 Dundee Horticultural Society's prizes, 71

ECHIVERIAS, MANAGEMENT of, 549  
 Echinocactus gonacanthus, 488;  
 E. Fendleri, 489  
 Edinburgh, proposed International Show at, 295  
 Edmonds, Mr., death of, 28  
 Electricity and vegetation, 46, 88, 128, 148, 270, 330, 402, 510  
 Electricity and the Vine, 330  
 Emigration, 411  
 Epacris at Chiswick, 267; select varieties, 289  
 Epidendrum bicoloratum, 358  
 Ericas, varieties for succession, 220; primuloides, 289; Cavendishiana, origin of, 479  
 Erinus alpinus, 487  
 Eriobotrya japonica, 297  
 Erythrina crista-galli, culture, 261  
 Erythroxylon Coca, flowering in London, consumption of in America, 255  
 Erythronium giganteum, 333  
 Espalier fence, forming, height of, 281  
 Essex (South) Flower Show, 504  
 Eucliaris amazonica, renovating unhealthy, 345  
 Euphorbia jaequiniflora propagation and culture, 356  
 Exhibitions, fixtures of, 361  
 Exhibitions, French v. English, 129  
 Exhibitors' grievances, schedule, 334  
 Exochorda grandiflora, 464

FARM—a retrospect, 1880, 16; retention of soluble matters by soils, 17; salicylic acid v. foot and mouth disease, 18, 37, 59; extinction of pleuro-pneumonia, Wheat-meal bread, 18; implements and machinery, 35, 57, 79; the Meehi fund, 37, 81; solubility of manures, oleo-margarine, sheep v. Lupins, 37; cropping arable land, seeds for pasture, 40; spring seedling, 57; food for ewes and lambs, Mangold Wurzel fly, 58; milk selling, impoverishing soil, the butter product, fluke in calves, 59; guano for Potatoes, feeding calves, 80; spurious butter, vegetable farming, 81; weeds, how to destroy them, 99, 119; chalk for land, roots for horses, 100; Birmingham Dairy Show, selecting stock, "Irish Farmers' Gazette," 101; malt for live stock, 120; food products, American, 121; floods, cause of, 121; fattening bullocks and sheep, comparative advantages of, 140, 159; estimated cost of feeding, 141; agricultural prospects, 142; preparing for spring corn, stable management, dairy cows, 161; the Meehi fund and Mr. Gladstone, cereals in India, Birmingham Agricultural Exhibition Society, presentation to Mr. Lythall, 162; salt for pasture, Prickly Comfrey, 164; Pasture lands, manuring and improving, 180, 200, 220; Mr. Lawes' experiments, 181, 200; milk, test for water in; Cabbages v. frost, Cart-horse Society, 182; Mustard and Cress, seed per acre, 184; fattening power of foods, 200; stabling horses, lambs scoured, remedy for, 201; farming in north of England, 202; feeding horses, 221; feeding calves, 222; management of machinery, 222; utilisation of waste land, 242, 262; Strawberry culture and yield, 248; sowing Mangolds, feeding bullocks, Italian cheese, 244; Potato culture, 246; mode, cost, and profit of timber growing, 263; American cheese, crops in Italy, "British Agriculture in 1880," 264; linseed cake for cows, 266; utilisation of waste land, 281, 302; timber growing, Robinias, value of, 281; seed for three years' lea, 282; adulteration of dairy produce, constituents of oleomargarine, uses of Maize, 283; warping, 303; sowing Barley and pasture crops, decorated cake, Strawberry farming, 304; Gourds for cattle, culture of, 322; agriculture in Ireland, reduction of rents, 324; ploughs, sowing Turnips, 346; implements and machinery, 345, 360, 387, 476, 498, 519; time for sowing Mangolds, Turnips, and Swedes, and manures for, 387;

#### FARM—continued

malt sprouts, 388; agricultural depression, Cork butter at Melbourne, 388; Channel Island cattle, 409; an estimate of agriculture, dairy farming project, 411; cross breeding of cattle, 430, 450; rot in sheep, Mr. McIntosh's shorthorns, 432; feeding stock, 452; flies and horses, 497; haymaking, experiments at Woburn, 498; extraordinary tithes, American Wheat production and transportation, 499; bran and meal for stock, 520; American Wheat deficiency, Birmingham Dairy Show, 521; agreement for cutting hay, 522; diseases of sheep and lambs, 541; rapid growth of grass, 542; art and science of agriculture, 542; pure seed, 542; Goat Society, 543  
 Ferns, raising from spores, 35; cutting down, 241; potting, 239; on blocks, 442  
 Ficus stipulata and its dimorphic character, 276; repens minima, 508  
 Fig trees, pruning, 3; not swelling, 78; in central Africa, 339  
 Flax, New Zealand, raising from seed, 302  
 Florists' flowers, notes on, 9  
 Florists' Societies (Northern) meeting, 71  
 Flower gatherers, 171; florists' and popular flowers, seasonable notes on, 91; spring flowers in Ireland, 170; extensive use of flowers, 379; pretty flowers for spring, 381; double flowers, 391, 437, 482, 484  
 Folk lore, provincial, 333  
 Fourcroya cubensis var. incrimis, 378  
 Frames, uses of in summer, 465  
 Freesia refracta alba, 171  
 Frost, severity of, 50, 71; duration and intensity of, 92; at Thornton Hall, Suffolk, 92; the great, 107; effects in Leicestershire, 112; extent of in January over the British Isles, 148; effects of in the Isle of Wight, 149; in June, injury from, 481, 486, 487  
 Fruit trees, root-pruning and summer-pruning, 12; in Bohemia, 152; dressing against sheep, 153; protecting, 170, 241; planting in Cornwall, 228; Mr. Simpson's book on, 333; at Chiswick, stocks, 352; prospects, 359; "Nature's plan," 372; blossoms setting, 378; pinching and summer pruning, 386; blossom injured, 396; blossom in Wilts, root-pruning, 436; pinching and root-pruning, 475  
 Fruits, growing for market, 308; a new Australian, 313; small profits of, 332; in Kent, Mr. Whitehead's essay on, 398; prospects in Essex, 465; in Surrey, glass structures for, 480; prospects of in Ireland, 512; unheated houses for, 513  
 Fuchsia rubra, 231  
 Fulham Nurseries, fire at, 23

#### GAGEA LUTEA, 360

Galvanised wire and fruit trees, 2, 21; sulphate of zinc, 21  
 Gardeners' (Royal) Benevolent Society, proposed augmentation fund, 375; objects of, 407  
 Garden party, first in Belgium, 397  
 Garden hose, 34; walls, references, 34; crops in Cornwall, 72; arrangements, notes on, 512; tents, 514  
 Garden, my, notes from in 1880, 68, 309  
 Gardenia citriodora, 31  
 Gardeners, duties of young, 262  
 Gardenias, culture of, 103  
 Gardening, future of, 1, 63; progress and taste in, school, 435  
 Garrya elliptica, propagating, 48  
 Gas lime for gardens, 56  
 Gillenia trifoliata, 520  
 Gishurstine, 8, 65  
 Gladioli, culture of, 149; "D. Deal's" experiences with, 166; notes on, 211; good varieties, 212  
 Glass broken in transit, claims for damages, 99  
 Glass structures and Vines for amateurs, 248  
 Glazed flower pots, 93, 509  
 Glazing, Fletcher's putty substitute, 169; without putty, 118, 150  
 Gloriosa superba, culture of, 130  
 Gloxinias, culture of, 228, 241; Mrs. Bause, 375; Lady Marriott, 422

Goniophlebium lachnopus, 336  
 Gooseberry bushes, pruning, 25; caterpillar, particulars of, 188, 208; for early green fruit, 495  
 Gooseberry and Currant fly, 412  
 fungus, 531  
 Gorrie, Mr., death of, 32  
 Grape oil, 9  
 Grapes, weight of at Charleville, 12; in Peach house, 15; weight of at Arkleton, 241; keeping at Longleat, 274; Australian, 441; low temperature for, 475; Duke of Buccleuch, 508; low temperatures for setting, 509  
 Gum liquid for flowers, 495  
 Gymnogramma schizophylla, 254, 274  
 Gymnostachyum, culture of, 322

#### HABROTHAMNUS ELEGANS, 361

Halesia tetraptera, 464  
 Haliaea nemorum, 311  
 Hamamelis virginica var. arborea, 114  
 Haworthia Bollerii, 254  
 Heating buildings, 12  
 Heating with paraffin stoves, 78; glass structures, 186; Weeks's hydro-caloric coil, 213  
 Hebeclinum lanthimum, 312  
 Hellebore Tea, 521; suggested remedy for phylloxera, 332  
 Hellebores in pots, 369; colechicus, 402  
 Herbaceous plants in Kensington Gardens, 291  
 Hewitt's, Mr., nursery at Solihull, 67  
 Hibbertias, notes on, 312  
 Hibiscus sinensis culture, 321  
 Hippeastrum pardinum, 132  
 Holly berries, deficiency of in Ireland, 8; hedge, pruning, 158; notes on planting, 294  
 Hollyhocks, culture of, 133  
 Honey-suckle, propagating, 261  
 Horn, dissolving, 56  
 Horticultural Club, annual meeting, 70  
 Horticultural exhibitions, prizes at, 10  
 Horticulture, results of, 128; plea and suggestion for, 489  
 Horticultural (General) Company's annual meeting, 92  
 Horticultural (Royal) Society's annual meeting, 168; Committees, 26, 114, 193, 231, 295, 335, 379, 394, 421, 488, 534; Great Summer Show, 457; Spring Show, 230; number of visitors, 464; Her Majesty's Commissioners, close of action, 487; results of litigation, 501; Mr. Justice Fry's judgment, 502; meetings, 530; Rose Show, Evening Fête, 534  
 Horticulturists, English, in America, 153  
 Hotbeds, making, 137, 180  
 Hot-water pipes, blacking, 56  
 House, Foster & Pearson's tenant right, 462  
 Housetop gardening, 344  
 Houstonia, dimorphic flowers in, 155  
 Hoya bella, 147  
 Hyacinths, Blue Roman, 92, 106, 170, 191; after flowering, increasing, 179; floriferous, 187; profliferous, 208; Magnificence, Primrose Perfection, 254; propagation and culture in Holland, 247; in Hyde Park, 329; Grape, notes on species, 351; wild for forcing, 481  
 Hylands Park Gardens, 463  
 Hypocalymma robustum, 289

#### IGGULDEN, MR., TESTIMONIAL to, 92

Imantophyllum minutum, 66, 397; cinnamum, 95, 112; Martha Reimers, 194  
 Incubator, fancier's, 37  
 Indian rubber plants from seed, 365  
 Insect haunts, 12; for gardeners, 47, 111, 174, 271, 311, 402, 438; 536; Miss Ormerod's observations on, 172  
 Insects—beetles, meal and cellar, 47; the Colorado beetle in Devonshire, 142; Lepisma saccharina, (Fish scale), 439; Orgyia antiqua (Vapourer Moth), 374; Scolytus destructor, 174; Tomichus typographus, 174  
 Ionopsisidium acule, 344  
 Irises, choice German, 319  
 Ixias and Sparaxis in gardens, 402; culture of in the open air, 429

JAMAICA PUBLIC GARDENS, 357  
 Jasminum Sambac, culture of, 220  
 Judd, Mr., testimonial to, 92  
 Juncus zebrinus, 331

KERRIA JAPONICA MAJOR, 336  
 Kitchen garden, seasonable work in, 278

#### LABEL FOR PLANTS, PRIZE for, 92

Lachenalias, Nelsoni, 114; at Gunnersbury, 232; tricolor, 271  
 Ladybird, larva of, 403  
 Lællis in winter, notes on, 10; L. anceps Barkeriana, 11; L. harpophylla, 254  
 Lavatera arborea variegata, 475  
 Lawn Edge-clipper, Adie's, 151  
 Lawn sand, Watson's, 429; mower, the Excelsior, 387  
 Lawns, destroying Daisies and Plantains in, 540  
 Leaves, movements in, 9  
 Ledum palustre, 437  
 Lepisma saccharina (Fish scale), 439  
 Lettuces, spotted varieties of, 119; early and successional, 177  
 "Letts's Atlas," 397  
 Liberian coffee, pamphlet on, 400  
 Libonia penrhosiensis, 191  
 Lichens on fruit trees, 375  
 Liege Royal Horticultural Society's Show schedule, 429  
 Lilies flowering, 378  
 Lilioms from seed, 126  
 Liliom Washingtonianum var. Scott Wilson, 489; L. monadelphum and L. szovitsianum, 540  
 Lily of the Valley, planting, 475  
 Lime, superphosphate of, uses, 495  
 Literary hash, 449  
 Liverpool Horticultural Association, 152  
 Loam, nature of, deep rich deceptiva, 350  
 Lomaria L'Herminieri, 442  
 Longleat, gardening at, 225  
 Loquat, fruit of, 297  
 Luffa aegyptia, 314  
 Lyeaste Skinneri, 273

#### MAIHIWAI—collecting crop of, 356

Mammillaria Caput-Medusae, 254  
 Manchester International Show schedule, 71; Spring Show, 233; Summer Show, 468  
 Manettias, notes on, 69  
 Manure, formula for artificial, 288; elements and action of, 510  
 Maranta crocata, 114  
 Maregravia paradoxa, 442  
 Marigolds, culture of, 372  
 Martynias, 13  
 McJwan, Professor, appointment of, 29  
 Meehi fund, 347  
 Megasea cordifolia purpurea, 336  
 Melons, culture of in cold frames, 205; cultural notes on, 258; temperature for, management, 318; culture in America, 357; and Cucumbers, culture of in frames, 465; stopping and pruning, 450  
 Meteorological Society, Mr. Symons' lecture, 67; Society's Meeting, 148  
 Meteorology, 269  
 Metrosideros floribunda, 456  
 Mexican Potatoes, 28  
 Meyenia erecta, 25  
 Mice, trapping, 16  
 Mignonette, Miles' Hybrid Spiral, 336  
 Millethia megasperma, 378  
 Mosses, lecture on, 29; mulching in America, 397  
 Moth Orchids, notes on, 234, 256  
 Mulching fruit trees, best time for, 252  
 Mulching, value of, 429  
 Muscari, description of species, M. szovitsianum, 351  
 Mushrooms in gardens, salt for, growing in sawdust, 45; in the Mammoth Cave of Kentucky, 530  
 "Musk Tree," 221  
 Mussenda frondosa, 89  
 Myosotis dissitiflora, 402; var. splendens, 420; azorica, 509  
 NARCISSUS ALBO-ALBETUS, 254  
 Nepenthes compacta, 355; N. ampullacea, 527

Nerme filicifolia, 378  
 Nesfield, death of Mr., 192  
 Newcastle-on-Tyne Horticultural Society, report of, 275; Spring Show, 290; good gardens near, 486  
 Nightingales near London, 368  
 Norwich Prolific Nut, 356  
 Nursery, the Pine Apple, 118  
 Nymphaea tuberosa, 130

#### OBITUARY—Benbow, Mr., 378;

Edmonds, Mr., 28; Nesfield, Mr., 192; Parsons, Mr. Anthony, 8; Sangster, Mr. John, 464; Shaw, Mr. William, 71; Spence, Mr., 31, 134  
 Odd corners uses of, 476  
 Odontoglossum Lehmanni, 231; O. Alexandræ Reglana, O. Ruck-erianum, 336; O. crispum grandiflorum, 375  
 Oleomargarine, 202  
 Omphalodes verna, culture of, 402  
 Onedidium eucallatum, 173  
 Onions, new and good, 65; culture for pickling, 368  
 Opuntia Rafinesquiana, 56  
 Oranges, grafting, 139  
 Orchards, decay of in Devon, 191  
 Orchids, notes on certificated, 6; Mr. Day's, 251; prices of, 274, 314; sale of, 379; Mr. Heywood's 269; at Kew, 380; at Wimbledon, 396; Mr. Bull's exhibition of, 420  
 Orgyia antiqua (Vapourer Moth), 374  
 Oval beds, forming, references, 34  
 Oxlips, results of sowing seed of, 354  
 Oyster shells as manure, 429

#### PEONIES—choice varieties, 319

Pansies, fancy, notes on, select varieties, 251, 272; for exhibition, propagating, 429; advice to purchase of, 529  
 Paraffin, dressing seeds with, 119  
 Paraffin tubs, preparing for plants, 153, 168, 190  
 Parrot eating feathers, 144  
 Parsley, Fool's, poisonous, 132  
 Peach trees—removing, 16; cutting down, 110; buds dropping, 141; disbudbing, 269; modes of cultivating under glass, the "extension" system, 327; extension training of, 354, 374, 382, 393, 395, 424; setting blossoms, 360; stopping shoots of, flowers dropping, 365; Noblesse for forcing, budding, 376; rendering trees fruitful, 402  
 Peaches, boxes for packing, 280 at Cardiff Castle, 437; leaves scorched, 449  
 Peacocks, Lord Beaconsfield's, 410  
 Pears Gansel's Bergamot, 7; branches dying, keeping fruit, 16; Bergamotte Hert-rich, 43; Durondeau, 73; Soldat Laboureur, 111; unpruned at Wimbledon, 396; for growing under glass, 429; blister moth, destroying, 475  
 Peasant proprietorships, 84  
 Peas—protecting from mice, for succession, 16, 35; early, forwarding, 29; new and good, 65; "Earliest of All," 132; Au-vergne, 159; early, modes of culture of, 85; sowing choice, 118; protecting from birds, 119, 126; mixed rows of, 186; hardness of, autumn sowing, 228; insuring a succession of, 302; for August, 318  
 Peat for potting, its constituents, 219

#### PELARGONIUMS—Guillon Man-

gilli, 43, 73, 314; for winter, 73; for winter, Charles Schwind, 150; good Zonals, 179; Charles Smith, 192; Zonals for winter, 210; select varieties, 219; cool greenhouse, zonals for winter, 288; new show varieties, 309; Crimson Vesuvius, 345; for winter, 356; pink Zonals, 373; as cut flowers, good varieties, 379; Mrs. Pollock, origin of 408; Henry Jacoby, 424; Mr. Henslow's lecture on, 422; good bedding varieties, 484; Chas. Darwin, Seedling 29, 489; tricolor, 528; Society's Show, 533; Pelargonium Duke of Albany, Mr. Ashby, Annie Hemsley, The Abbott, Magnet, Superb, Britomart, and Belle du Jour, 534  
 Pelham pillar, 132  
 Perfumery in America, 357  
 Peristeronic Society's Show, 40

Perry, death of Mr., 92  
 Petunias at Perry Hill, 330  
 Phalus tuberosus, 194  
 Phalanopsis — P. Schilleriana, 235; at Chelsea, 113; notes on species 256; P. Maunii, 257; P. violacea, 331  
 Philadelphus mexicanus, 480  
 Philodendron elegans, 375  
 Phloxes, good varieties of, 219; choice, 391; notes on and select varieties, 374  
 Phylloxera and its eradication, 413  
 Pigeons—sale of Mr. Hudson's, 18; Wood, raid against, 58; unhealthy, Toy Pigeons, Helms, 81; Cassell's Book on, 101; sale of Mr. Waters', 121; African Owls, 204; Homing in Germany, 304; instinct of, 306; Homing, 285; as birds of war, 324; Toys, proposed society for, 347; Ice Pigeons, 348; notes on, distinguishing sex of, 348; Toys, Turbites, 390; property in homing, judicial decision, 412; flight of Homing, 452; Oriental Frilled, 500  
 Pine Apple, Lord Carrington, 295  
 Pitcairnia zeifolia, 130

PLANTS CERTIFICATED—  
 Actinopteris radiata australis, 254; Adiantum monochlamys, 296; Agave Huntii Parryi, 375, 531; Amaryllis—Storr's Beauty, Empress of India, Cecilia, Madame Albani, 254; Mr. Henry Little, 231; John Heil, Royal Standard, and Miss Alice Gair, 194; Anthurium Andreanum, 254; Arafia Chabrieri, 389; A. Kerchoveana, 336, 375; Asparagus tenuissimus, 336, 375; Asplenium Saundersoni, 254; A. Baptisti, 194; Astilbe Thunbergi, 422; Auricula Mrs. Wm. Brown, Philip Frost, John Ball, Lizzie, Hilda, 375; Mabel, 316; Splendour, Miss Moore, 336; Azalea Madeline, 422; Roi Leopold alba, 254. Begonia Davisii flore-pleno superba, 380, 445; Mrs. R. Whyte, 445. Caladium Fredk. Bause, 375; candidum, Mitridate, and J. R. Box, 489; Calceolaria Cloth of Gold, 422; Carnation Andalusia, 26, 64; Lady Musgrave, 489; Cineraria Master Colvin, and William Jennings, 114; Mr. H. Little, 194; Marched Past, 236; Clematis W. E. Gladstone, Lady Constance Kennedy, Geo. Elliot, 442; Princess Beatrice, 504; Celogyne cristata alba, 254, 296; Colcus Miss Simpson and Mrs. Stedall, 459; Croton Lady Zetland, 375; Cyclamen persicum Lilian Cox, Charming Bride, 194; Queen Victoria, Ruby Gem, 231, 254; Cyperus laxus variegatus, 375; Cypripedium selligerum majus, 489. Davallia elegans polydactyla, 336, 375; Dendrobium litiflorum candidum, 231; Dracena Linden, Alexandra, Rossi, recurva, 375; Dioscorea refusa, 296. Echinocactus gonacanthus, E. Fendleri, 489; Erythronium giganteum, 336. Fuchsia rubra, 231. Gloxinia Mrs. Bause, 375; Radiance, 380; Lady Marriott, Brantome, Fabiola, 422. Gonolophium hachnopus, 336, 375; Gymnogramma schizophylla, 254, 296. Hamamelis virginica var. arborea, 114; Haworthia Bollei, 254; Hyacinth Magnificence, Primrose Perfection, 254; Hydrangea Mariesii, 489. Imantophyllum miniatum Martha Reimers, 194. Juncus zebrinus, 531; Kerria japonica major, 336. Lachenalia Nelsoni, 114; Lælia harpophylla, 254; Lilium Washingtonianum Scott Wilson, 489. Mammillaria Caput-Meduse, 254; Maranta crocata, 114; Megasea cordifolia purpurea, 336; Mignonette, Miles' Hybrid Spiral, 336. Narcissus albo-aureus, 254. Odontoglossum Alexandræ Regina, O. Ruckerianum, 336; O. crispum grandiflorum, 375; Omphalodes Kramerii, 296. Pelargonium Eureka, 26; Anna Fitzzer, 296; Mr. Henry Cox, 422, 445; Martial, 445; Charles Darwin, Seedling 29, 489; Duke of Albany, Mr. Asby, Annie Hemsley, The Abbot, Magnet, Superb, Britomart, and Belle du Jour, 534;

PLANTS CERTIFICATED—cont.  
 Phaius tuberosus, 194; Phalanopsis violacea, 331; Philodendron elegans, 375; Pinguicula Bakeriana (caudata), 296; Polyanthus Hosi-in-Hose, 336; Primula The Queen, 194; Dr. Denny, 114; Primrose Amaranth, 296; Cloth of Gold, 383. ### THE FUTURE OF GARDENING.

I CANNOT but believe that there is a great and successful future for gardening and gardeners, and that gardening will be carried on in coming years on a scale far larger than ever before. I do not allude to gardens as luxuries, but to gardens as a source of profit.

The farmer's prospect is gloomy enough. He cannot grow his crops to pay, or pay well. He is threatened with rivals in the meat market. Many farmers have collapsed, and I fear more will. The majority of these, though by no means all, have been idle, or extravagant, or vicious, or wanting in energy. I have known some even, unfortunately, who have eaten their dinner this Christmas in the workhouse. In every great alteration of course many go to the wall. Thus the introduction of railways ruined many coachmen, guards, and hangers-on at stables; but others adapted themselves to their new circumstances—and happily there is much adaptability in energetic men—and such were not ruined but threw themselves and their powers in other and more profitable directions. It will be the same in this farming matter.

The point I wish to impress upon our readers this new year is, that gardening should be extended into the domains of agriculture. No longer should it be confined within the traditional four square walls of a garden properly so called, but should embrace a large tract of country, particularly that lying around and near towns.

Sir Gabriel Goldney, a particularly practical and far-looking member of Parliament, when recently addressing a large agricultural gathering, amid other remarks said, "I see from the agricultural returns that no less than a quarter of a million acres of land had during the past fourteen months been turned into orchards and market gardens, and with the result of materially augmenting the profits, considering the small time the land has been devoted to that purpose." But I am sure this plan and change can be carried further. Why should a single Apple be imported from America? I would say, Let land under the plough be planted with Apple trees. Of course the plough must not go quite up to the trees and so injure their roots. By planting the trees on such land they would be far less likely to be injured by the knives of idle mischievous boys, for a ploughed field is no pleasant place to stroll upon, as is a meadow; also the sun and air would get better to the roots, where was no entangling grass; and remember grass is only weeds. Then further, when the trees began to fruit, the crops on the land would protect them from the pilfering of

the afore-mentioned mischievous boys, who will, boy-like, eat fruit in its green state. Then, when the corn is cut, the Apples too will be ready to be gathered. The Apple crop is a very fairly certain one if proper arrangements are made, such as planting in a right aspect and planting proper varieties of trees. Let our great fruit-growers state what trees are the best—i.e., what they have found to be the best. Again, in England only and a few savage countries are lumps of meat consumed, and very expensive lumps they are. Look at the economy of French cookery; and even the very Chinese never think of providing for themselves or guests thick lumps of meat as we do. Vegetables most certainly ought to bear a larger proportion in our meals, but town populations simply cannot get them; but if large districts around every town were devoted to the production of vegetables the middle and lower classes would soon see the benefit and economy of becoming purchasers.

All vegetables except Carrots are wholesome, and if children are early trained to eat them they prefer them to meat. Two things no child naturally likes—the one is beer, the other meat. Nature teaches it that water and milk suit it far better, and the child's delicate palate loaths the medicine-like taste of beer, and pudding and vegetables and fruits suit its stomach better than meat. There is an old story of a Frenchman coming to an inn where four Englishmen had the only joint to be obtained turning on the spit for them—viz., a leg of mutton, which they stoutly refused to allow the Frenchman to share. "But," said the Frenchman, "would Messieurs allow me to put a knife here and there into the meat, and permit me also to have some pieces of bread and vegetables placed beneath?" The permission was given, and the knowing Frenchman had a tasty pleasant dinner while the Englishmen had a dry piece of meat.

I would instance a vegetable which is not nearly eaten cooked and from a dish as much as it might be—viz., the Onion; and those that are, are Spanish and not English Onions. An Englishman eats little Onions, sometimes far earlier in the day than is agreeable to those who talk to him; then he has them sliced around his beefsteak—another lump of meat—but how few have a vegetable dish full of large Onions of English growth stewed for supper! And yet no supper is cheaper or more wholesome. A poor tradesman's family might sup for a few pence on them and bread and salt, yet where are the Onions in any great number to be bought cheaply? Yet Onions may be grown in fields with profit. In another part of Sir Gabriel Goldney's address he thus speaks of this as a paying crop:—"A friend of mine was induced to follow the advice I gave him in regard to Onions, and when I was out shooting recently he drew my attention to two acres of Onions he had planted. My friend told me the difficulty he had was to keep his crop clean, and that was essential in their cultivation; but it had been properly carried out, and the result was that he had a magnificent crop. He had calculated to a nicety what expense he had incurred, and had found that with seed, rent of land, and so on, the cost had been as nearly as possible £20 an acre. He had had an offer for the crop from a man in the immediate neighbourhood of £37 an acre, but he thought he was entitled to have £40." "Supposing," adds Sir Gabriel, "this could be carried out to a larger extent, a profit of £17 an acre would be a very satisfactory result." Here, then, is one means to a desirable end. I make no apology for writing thus agriculturally in a "Journal" which,

though it be one "of Horticulture," has a division entitled "Home Farm." It appears to me that a little energy added to a power of adapting himself to altered circumstances may yet save the farmer; but it is no use going on just as his father did before him, it is a case of change front to face difficulties successfully. Folding the hands in difficulties is bad—it is idle. Wringing the hands is womanish, weak, and useless; but change of plans on consideration and calm judging, and then going on energetically in the new and probably prosperous path, is the part of a man.

In regard to gardening properly so called I must in these days read a lesson to gardeners on the absolute duty of economy, and to put masters on their guard too. Says a popular writer, "We have heard divines say that of all recreations gardening is the most innocent. They are probably right, speaking in a general way, but there are instances in which this innocent recreation would appear to be the veritable 'mischievous still' spoken of by the poet as readily procurable for idle hands. Let a man once taste the secrets of high gardening, unless his moral courage and self-denial are of an equally high order he is pretty certain to run into extravagance over his hobby. He is always longing for more glass, or constantly increasing his horticultural staff and imagining it will all pay in the end; but it does not, and the result is his garden is the heaviest item of his annual expenditure. Extravagance in a garden is no more virtuous than extravagance in a stable." These are words to be well weighed. But if masters and men determine that good gardening and economy shall go hand in hand then all will be well. No blaming then of the gardener; no reproaches of the wife cast upon the husband for his spending too much on the garden. The very same reasoning may be applied to the expenses of the poultry yard and the Pigeon loft. Remember, while hobbies give pleasure, no hobby gives unalloyed pleasure if in its gratification there is extravagance or more money spent than a man can properly and rightly afford. Ride your hobby but do not let it ride you, and then you will be safe, cheerful, and have no twinges of conscience. These are plain words of advice, but I hope will be pardoned from one who writes them in this his seventeenth annual address.

I have entitled this paper "The Future of Gardening," and I believe that future will be nationally valuable. Progress is the order of the day. An invisible hand seems to be on the shoulder of the gardener with the words, "You must go on, and go on to the benefit of Great Britain." Wonderful has been already the progress in gardening. The population of England is rapidly increasing in towns and decreasing in villages. Each time the census is taken it is found that there is an increase of population in very few villages. Some are stationary, many have less and less inhabitants: the population is centring in towns. Then, of course, these centres need more and more food, and in a larger area around towns should vegetables and fruit be cultivated. Further from towns land suited for rabbit warrens should so be used. Poultry farms, with many runs and houses distinct from each other and moveable, would also pay, and the importation of eggs might at least be diminished. This centring of the population in towns must be carefully noted to the benefit of renters of land near towns, because an increase of population will and must provide a continually larger market for all perishable kinds of food; and so a continually larger and larger space of land may be profitably devoted to the cultivation of fresh fruit and vegetables, and to the providing of milk and fresh butter.

Another point. Is it a wild dream, too wild for realisation, that towns in the future will not be the crowded places they now are? Why should not the gardener enter the streets and plant trees there, bare the banks of rivers of warehouses, and have trim and pleasant and flower-edged walks by the river? A grand mistake was made in the middle of the last century in regard to Bath, "that beautiful city," says Lord Macaulay, "which charms even eyes familiar with the masterpieces of Bramante and Palladio;" and "the only place worth living in except Florence," says Walter Savage Landor. Yet how more beautiful would even Bath have been had not in the last century houses been built on the river banks, and the very course and sight of the stream lost to sight!—if instead of these

houses there had been broad shady walks, and grass-grown banks bordered the bright and rapid-flowing Avon! But surely in the towns of the future there should be, and may be, a wider area, with trees in every street, and large gardens for fruit and flowers to every house. "Then our towns would be made really living places," says one; adding that "the farmers round, instead of striving fruitlessly to contend with more favoured climes in the production of golden grain, will find a more profitable employment in providing the children of artisans with the fresh milk so essential to a healthy-going life, and the good butter and fresh eggs so unattainable now-a-days." And if so, again would England be a "merrie England."

If such a dream should be realised—(and the gardener must to a great degree be the man of the future, and gardening be carried further and further to the benefit of individuals, and render England happier and healthier)—beauty and utility would go hand in hand, taste would be raised, aye, and morals too. Meanwhile that gardening may this year prosper; that gardeners, amateur and professional, may meet with success; that this new year may be a happy year to all readers and writers of this "our Journal," is the earnest wish of—  
WILTSHIRE RECTOR.

#### AUTUMN FLOWERING OF AURICULAS.

YOUR correspondent "R. P. B.," asking why Auriculas bloom in autumn, replies to his own question when he says that "all spring-flowering Primulas have a tendency to bloom in autumn and early winter after a hot dry season."

The remark might safely be more general, in that all Primulas are spring-flowering, earlier or later, and may bloom in autumn whether the summer has been hot and dry or not.

The Auricula sends up flowers in the autumn simply because it is a Primula; and this habit is so deeply rooted in the family, and not least in this branch of it, that probably it is impossible to eradicate it, though it may be considerably lessened in several ways.

Some varieties of the Auricula are constitutionally more given to autumn blooming than others, and the fewer your correspondent has of these uneasy sorts the less of course will be his average of autumn bloom. If he raises seedlings he will again find this tendency much more marked in some than others, and may again put aside those that persistently trouble him with flowers at a time when they can only be comparatively feeble and immature.

I should not like to say that keeping Auriculas of any value wet, "with abundance of water through the summer and autumn until the cold of winter stops the growth," is good culture. Neither do I know how it would stop autumn blooming, or be a healthy way of attempting to do so with valuable plants, not always of robust constitution, especially if they are kept very wet.

From my own experience I submit that it is far safer to keep Auriculas very cool all summer, and but very moderately moist; and if this treatment succeeds with the most highly developed florist forms of the flower it is probable that commoner varieties of heartier growth would thrive under it too. Air and light, coolness and good drainage, are necessities of life to the Auricula, but through the summer I have found them always crisper, stouter, quieter, and greener without much water or exposure to sun.

If it seems cruel to discard any varieties of the Auricula (I allude to the florist sections) because of a habit of autumn blooming, it is only necessary to explain that the plants which do so are very seldom able to form a new heart strong enough to produce a full truss in proper character next spring.—F. D. HORNER, *Kirkby Malzeard, Ripon.*

#### GALVANISED WIRE AND FRUIT TREES.

(Continued from page 589.)

RELATIVE to the absorption of muriatic acid by wire that has been immersed in it preparatory to being coated with zinc, as referred to on page 588 of the last volume, an eminent horticulturist has informed me that the acid does penetrate iron and afterwards escape from it. A few weeks ago the metal shield on the stock of his rifle—the "butt end"—became rusty, and in order to remove the rust expeditiously he applied some muriatic acid instead of scouring the metal in the ordinary manner. The part was quickly cleansed, well oiled, and the rifle "put away." A few days afterwards he was surprised to find that the acid absorbed had exuded, destroyed the effects of the oil, and the

metal was as rusty as ever; it was then cleansed, but not with acid, and oiled again, and the same results followed. The cleansing and oiling were repeated, and still the acid escaped, rendering the oil useless; and he has no doubt that if a Peach shoot or the young growing lateral of a Vine had been placed in contact with the metal the escaping acid must have injured them. This supports the statement of the individual alluded to last week, that the acid escaping from the wire must be injurious. I have a little further testimony to adduce in support of that view. On my questioning the soundness of the theory the propounder of it replied, "We will soon settle the point," and he obtained some pure zinc wire and fixed it amongst the other kinds of wire in a small house of Vines where some experiments were being conducted, and remarked, "There! there is no acid in that wire, and it will not hurt the Vine shoots, see if it does." It has not injured them, for the one solitary speck on a shoot that was secured to it was so slight as to amount to "no injury," while others in contact with some samples of galvanised wire were seriously and unmistakeably corroded. This, as the matter now stands, looks almost conclusive, but on proceeding further we shall find one or two obstacles to that mode of settling the question. The first is perhaps not a very serious one, but it must be mentioned for what it is worth. The pure zinc wire was not obtained until the so-called galvanised wire had been on trial two months, and thus the former was not submitted to an equal test in point of time; and as the Vine laterals were more sensitive of injury early in the season than later, the pure zinc wire was not so fully tested as could be wished. The next is a far more formidable impediment against the conclusiveness of the "escaping acid" proposition, and opens up another aspect of the general question that demands careful consideration. I must, however, record that the propounder of the above idea states that while the acid in the iron will escape through the coating of zinc it will not penetrate through two or three coats of good lead paint—a statement that has received abundant confirmation.

Now to the great difficulty No. 2. When discussing the electricity theory on page 568 (last volume), I stated that while that element is undoubtedly general, I should be able to show pretty conclusively that the injury resulting to trees and plants in contact with the wire under notice is markedly local. That remark has caused a little surprise, and its accuracy has been doubted. It was founded on the published statements of the many writers who took part in the discussion on the effects of galvanised wire last spring.

On careful perusal of the several communications one striking fact comes to the surface that, I think, must not be lost sight of, as it appears to be of considerable moment. It is this: Every writer save one who adduced testimony of the injurious effects of galvanised wire recorded his experience as it was gained within the smoke radius of some large city or town, or in contiguity to some works or manufactories that contributed to the impurity of the atmosphere; and, on the other hand, in every instance where a writer gave contrary testimony—namely, that the wire was not injurious, he resided far remote from large towns and in the pure air of country districts. I have had one letter from a country gardener whose trees have suffered by the cause indicated; but the substantial fact remains that it is within the smoke "measurable distance" of London, Liverpool, Leeds, Derby, Sheffield, Wakefield, &c., that the injury has been severe; while writers residing in the "truly rural" districts of north and south Yorkshire, Lincolnshire, Sussex, Wiltshire, and East Surrey have all pronounced the wire perfectly safe. I have visited the majority of the places named and am convinced of the accuracy of the statements. I have also employed the wire in the country without any signs of injury resulting, while near London it has proved most decidedly injurious. It has either had to be removed or painted in numbers of gardens near towns, including the Royal Horticultural Society's Gardens at Chiswick, but in remote rural districts recourse to such measures have very seldom been rendered necessary. I submit, therefore, that there is justification for regarding the injury as "markedly local," for it exists in the most unmistakeable manner where smoke more or less prevails, and the greater the smoke the greater the injury, while in the pure and salubrious air of the country the evil is comparatively non-existent.

Bearing in mind this element of the case, it necessarily follows, if the injury is solely due to the acid escaping from the wire, that all the wire that has been the most saturated with the acid has been employed in the vicinity of towns, while all that has only had a slight acid bath for cleansing it has been sent into the country. This result is so extremely improbable, not to say impossible, that the proposition under notice that at first looked so feasible becomes seriously weakened. That there is "something

in it" is possible, even probable, but it does not appear to afford a solution of the question by any means satisfactory.

We now arrive at Mr. Taylor's suggestion, that the impurities of a smoke-laden atmosphere may be brought down by the rain in contact with the wire, and, combining with the sensitive zinc coating, produce a result noxious to vegetation. This is not at all unlikely—is, indeed, very probable; but injury has been serious under glass where the rain has not penetrated, and in some cases where the syringe has not been used. In the structure in which different kinds of wire have been employed one Vine has been syringed occasionally, and it has sustained the greatest injury, but the four other Vines that have not been syringed have been seriously enough affected; so that water is not the sole medium of producing the noxious irritant, and we must look in another direction for a solution of the problem.

I had hoped to have concluded the subject this week; but it is so intricate, and the divergence of opinion relative to it is so great, that the examination of the question must be as close and thorough as possible, as dealing with it in a superficial manner could not possibly give satisfaction. The concluding notes, with a reference to some experiments, must therefore be deferred to a future issue.

—J. WRIGHT.

#### SERICOGRAPHIS GHIESBREGHTIANA.

THIS old inhabitant of our plant houses is now gay with its light sprays of scarlet flowers. Individually its flowers are not very showy, but the profusion in which they are produced renders them very attractive. Where autumn and early winter flowers are required it is surprising this useful old plant is not more largely grown. When in flower it thrives either in the conservatory or in the stove, but in cool quarters the flowers last best. The cultivation is simple, and dwarf plants are admirably adapted for room or table decoration; and although it is classed amongst stove plants, it thrives well under cool treatment and requires but little heat. Useful plants can be grown in a season from cuttings, and if larger plants are required the old specimens can be cut back, partially shaken out, repotted, and grown on. Propagation is easily effected by means of cuttings in spring. The tops of the shoots root freely; or the suckers that are often produced from the bottom. A number can be inserted together in 5-inch pots or singly in small pots, which is the better plan, as every cutting is sure to strike. The small pots should be filled with sandy peat, watering the soil as soon as the cuttings are inserted, which will root freely with or without a propagating frame if placed in moderate heat. The process of rooting is quicker in a frame or under a bellglass. When rooted the young plants should not be subjected to too much heat, or they soon become weakly and a prey to scale. A temperature of 55° to 58° is sufficient, as the plants grow more sturdily, and when stopped branch more freely. This plant is of upright habit, and requires to be pinched when only a few inches high. This is an important operation to form bushy plants.

When the plants require potting sandy loam and a small proportion of manure form a suitable compost, in which they will do well. They must not be left in the small pots too long, or they are very liable to be seriously checked. When the external temperature is sufficiently warm artificial heat can be dispensed with through the summer months. Syringing and early closing the frame or house in which they are grown encourages free growth during summer, and good plants can be obtained in 5 and 6-inch pots, which are large enough for all ordinary purposes. Stopping must not be done late in the season, as the growth must be thoroughly ripened to ensure the satisfactory production of flowers. After the final potting and when the pots are full of roots supplies of liquid manure must be given, and while growing liberal applications of water are needed both at the roots and upon the foliage. In early autumn when the nights become cold the temperature of 50° should be maintained, which is ample to bring the plants into flower.—WM. BARDNEY.

#### PRUNING FIG TREES.

"WOULD you kindly inform me if wood like the enclosed examples should be cut out now the trees are at rest? Will such wood bear in the coming summer? The trees were planted out last February in a span-roofed house and have borne a good crop of fruit, being large trees. Must they be pruned something like Peach trees?" Thus writes "A NOVICE" to us; and as he submits both fruitful and unfruitful wood we cannot make the subject so plain to him as by the aid of the following figures and instructions, written by a skilled cultivator of Figs, and which can scarcely fail being useful to others as well as to our correspondent.

The first crop of the fruit of a Fig tree is borne on the wood of the previous season's formation, as represented by fig. 1, the young embryo fruit being shown at *a*. That of the second and succeeding crop is produced in the axils of the leaves on the wood of the current season's formation, which will be represented hereafter. Fig. 2 represents the remnant of the last crop of fruit of the previous season as they are to be seen frequently on the plants after the fall of the leaves in autumn. These fruits are ignorantly believed by many to be those which form the first crop of the following year, and are jealously protected throughout the winter on that account. They are, however, merely late fruit of the past season which failed to arrive at maturity through want of heat or the conditions required for that end. These fruit

Fig. 1.

are not worth consideration. A few may, under very favourable conditions, remain on and ripen, but very seldom.

Fig. 3 is a representation of a shoot having wood buds only.

These three figures, then, represent the different characters of shoots with the position of the fruits, &c., as they are commonly

Fig. 2.

Fig. 3.

to be met with on a Fig tree at rest during the winter time. Where the wood is well ripened and in its best conditions, as will be found with pot plants and trees in houses, shoots, as in fig. 1, will predominate. A little will, however, depend upon the varieties; and when the wood is badly ripened, as where the shoots are crowded, those with wood buds only, as in fig. 3, will be produced. It is necessary to fully understand the characters

and the offices of each of these before attempting the office of pruner.

**PRUNING.**—It is an old saying, "that a pruned Fig tree never bears," which is to a certain extent true, but only with relation to the first crop, or with trees in the open air, or where sufficient heat is not available to ripen the second crop. This must be distinctly understood—that it is entirely owing to the want of heat if the second crop of fruit is not obtained, either in relation, in the first place, to immaturity of the wood which fails to produce fruit, or to the fruits being produced and failing to ripen, as shown by fig. 2. Knowing, then, whence and how the fruits are all produced we are enabled to prune with certainty for a required end. If we cut back the fruit-bearing shoots (fig. 1), we destroy the first crop of fruit, and if heat is wanting the second crop also, the shoots produced after pruning being very frequently of a watery and unfruitful character. Fig trees bearing shoots, as in figs. 2 and 3, may be pruned without any loss of crop. It is, however, clearly shown that to prune a Fig tree to any extent is a distinct loss of fruit. As, however, the operation must at times be performed to keep the trees within form and limits, it is my duty to show how that can best be done at the least sacrifice, and this must be considered under various conditions.

1, Trees on walls and as standards in the open air will, if pruned (by which is meant that particular shoot), through the want of heat or the shortness of the season, produce no fruit; so that, excepting in extreme cases, a portion only of the shoots should be cut back.

2, Trees planted out in houses with or without heat, being generally inclined to vigour of growth, will, if pruned, produce gross shoots, and consequently but seldom produce fruits that season. In this case also partial pruning only is advisable.

3, Trees in pots having their roots entirely under the control of the cultivator, and the wood being properly ripened, will, if pruned, produce an abundant second crop.

In the first example it is the first crop of fruit only which can be depended on under any circumstances. In the second example both the first and second crops may be secured if the trees are unpruned, but not otherwise. And in the third example, with trees in pots, by non-pruning we secure the first crop, and by pruning, the second and frequently a third crop. Only with pot trees, then, can pruning be effected with a certainty of a crop the same season. If in this case, then, the first crop is desired, the shoots as in fig. 1, must not be cut, excepting just a few here and there to keep the plant in trim. All shoots, however, bearing only wood buds, as in fig. 3, may be shortened back if necessary, with exactly the same result as to fruiting as if left unpruned.

Pruning should be performed as soon after the fall of the leaf as possible, in whatever situation the trees may be, whether in pots under glass or in the open air. When the trees are pruned at that season, the plant being at rest, the wounds are soon healed over and no injury is sustained; whilst, if the operation is delayed until late in spring, when the sap is again in motion, there is such a volume of sap and it is of that nature, that the shoots are apt to die after the knife: hence another of the reasons against the pruning of the Fig, which we are warned against in nearly all the writings on the subject.

Bush or half-standard trees when planted out are extremely apt to grow too luxuriantly, and in consequence become unfruitful. The shoots should be kept very thin, so as to obtain all the sun's influence possible to thoroughly ripen the wood, and in the summer the young growing shoots should be vigorously pinched, in order to check luxuriance and bring the tree into a stubby fruitful form of growth.—A. B. C.

#### DROSERAS.

MUCH has been written from time to time on Sundews, and much more could be advantageously written. All the species of Sundews are peculiar and interesting—peculiar from a structural point of view, and interesting on account of their carnivorous or insectivorous propensities. The genus *Drosera* embraces about eight or nine species known to gardens, but there are many species described that are not in cultivation. They are found growing nearly all over the world where there are bogs. Of the cultivated species *Drosera binata* (dichotoma) is by far the largest, and the species from Australia are much more elegant than our British forms. *Droseras* have no economic properties, but Dr. Lindley remarks that the viscid fluid with which the hairs are furnished is said to curdle milk and to remove warts, corns, freckles, and sunburns. It has been said to cause the rot in sheep. The virtues ascribed to it may be real or imaginary, but with respect to its mischievous effects on sheep there can be no doubt that where Sundews grow there flocks are not likely to fatten, for

the herbage with which it is associated is mostly Moss, Rushes, Cotton Grass, and other weeds. All the species of *Drosera* known to gardens are easily cultivated, and anyone having an ordinary greenhouse could succeed in growing them through the summer. My collection of Sundews is in an ordinary greenhouse in summer, associated with *Sarracnias* and *Darlingtonias*, and they succeed remarkably well. The British species are scarcely worth cultivating, excepting *D. longifolia* and *D. rotundifolia*; the latter when grown in a shallow pan is a charming plant. Some of the species are deciduous, and die down to the soil at the latter end of autumn; they should therefore not be excited to growth through the winter months, and in spring they will break away more vigorously. Spring is the best time to pot them, before they commence growing. The soil I employ consists of fibrous peat, chopped sphagnum, and silver sand, with a sprinkling of charcoal broken rather finely, which suits them very well. Some of the smaller-growing forms succeed better singly in small pots, whilst *D. binata*, *D. spathulata*, and *D. Whittakeri* look more effective in small pans. When the plants are growing they require abundance of water; in fact, the soil should never be allowed to become dry. I find that a neat top-dressing of green sphagnum on the surface of the soil sets them off to great advantage.

Perhaps a brief description of some of the species will not be out of place, I therefore give the following selection:—

*Drosera binata*.—This is the most showy and handsome of the genus. It grows from a foot to 18 inches high, and nearly as much in diameter. Small plants should be grown in pots, but if desirable to make up a specimen several roots can be placed together in a pan. The leafstalks grow rather weakly, so it is advisable to secure the largest to neat stakes; the small leaves will support themselves between the others. If any roots are broken off in potting they may be cut into lengths and potted, which in time will form young plants. The flowers are large and pure white.

*D. capensis*.—This comes next in size, growing to a height of from 5 to 6 inches. It is best grown singly in a pot, the soil being surfaced with sphagnum, and if plunged in a small pan a surface covering of Derbyshire spar is suitable. After the plant has become tall the top may be taken off and inserted as a cutting, allowing the parent plant to start into fresh growth. The roots of this species may also be propagated from, but when plants are sufficiently large they will flower freely and produce abundance of seeds, which may be sown as soon as ripe. The flowers are a light pink colour, rather large and showy, but unfortunately only last a few hours in perfection.

*D. spathulata*.—A charming little plant, but instead of growing erect it has a spreading habit, the leaves being much broader than the first-named species. I find it succeeds well in a small pan, placing five or six plants together, allowing each sufficient room to develop fully. This species also produces seed freely, which may be sown when ripe, and when the plants are large enough to handle may be pricked off into a small pan, covering them with a bellglass until they are a fair size.

*D. Whittakeri*.—This much resembles the last-named species in habit, but grows more erect. It is one of the deciduous forms, and requires a long rest. It has small tubers about the size of a round pea, and before starting into growth should be taken out of the old soil and repotted into a richer soil. *D. Whittakeri* is rather scarce in this country, and is seldom seen in collections.

*D. filiformis*.—A little gem, and should find a place in every collection. It requires a little more heat to grow it well than most of the other species, being very tender and sensitive to cold draughts. I grow my plants in small 60's, and in order to obtain a good specimen I plunge five or six together in a pan.

*D. rotundifolia*.—This is the best of the British species for growing under glass, and when covered thickly with dew it is by no means to be despised in pans. Any light peaty soil suits it, and all that is required when growing is abundance of water at the roots. *D. rotundifolia* is a very free bloomer, and if the flowers are permitted to remain on the plants they very soon produce seed pods, which to a certain extent checks the growth. I find it a capital plan to remove the flower spikes as soon as they appear; by so doing the plants keep growing till quite late in the season, the leaves attaining a greater size. I will, perhaps, give at some future time a few notes on *Drosophyllum lusitanicum*.—W. K.

**SELECTION OF VEGETABLES.**—In the selection of vegetables given by Mr. Muir at page 592 of your last volume, he names the following Peas—viz., William I., Carter's Stratagem, Carter's Telephone, Culverwell's Telegraph, Laxton's Omega, and Ne Plus Ultra. The two latter are late varieties, the first named early,

and the other three main crop Peas. In these days, when we are obliged to study economy in the garden, it would be of interest to know the proportion of each of these Peas Mr. Muir would recommend to be purchased for a garden requiring 16 qts. for seed purposes, and the cost of the same.—R. P. BROTHERSTON.

#### PLANTS FLOWERING AT CHRISTMAS IN CORNWALL.

I ENCLOSE you a list of plants that were in flower on Christmas day, 1880. The lowest temperature recorded this winter is 34°. The weather at present is extremely mild and spring-like. Cornwall is indeed the botanic garden of England, for out of doors I have noticed lately flourishing magnificent specimens of *Dracæna australis*, *Embothrium coccineum*, *Imantophyllums*, *Coprosma*, Orange plants, *Agapanthus umbellatus*, *Aralia Sieboldi* 7 feet high in flower, *Seaforthia elegans*, *Ficus repens*, *Dicksonia antarctica*, *Phormium tenax Veitchii*, *Hedychium flavum*—this flowered beautifully out of doors last summer. The following were in flower at the time mentioned:—

*Arbutus magnifica*, *Antirrhinum*, *Alyssum*, *Anthemis nobilis*, *Aucuba japonica*, *Arabis albida*, *Aralia Sieboldi*, *Armeria maritima*, *Auriculas*, *Aubrieta græca purpurea*, *Borage*, *Brompton Stock*, *Berberis Darwini*, *B. vulgaris*, *Camellias*, *Cassia corymbosa*, *Calceolarias*, *Chrysanthemums*, *Campanulas*, *Ceanothus azureus*, *Clematis Jackmanni*, *Cuphea platycentra*, *Correa cardinalis*, *Cotoneaster microphylla*, *Carnations*, *Chorozema macrophylla*, *Daisies* double and single, *Desfontainea spinosa*, *Escallonia macrantha*, *E. montevidensis*, *E. Ingrami*, *Erica carnea*, *E. ciliaris*, *E. gracilis*, *E. codonodes*, *E. mediterranea*, *Fuchsias*, *Myosotis*, *Zonal Pelargoniums*, *Geranium Robertianum*, *Gazanias*, *Glastonbury Thorn*, *Gunnera scabra*, *Garrya elliptica*, *Hydrangea*, *Helleborus niger*, *Iberis gibraltaria*, *Ixias*, *Lapageria rosea*, *Laurustinus*, *Lobelias*, *Lychnis diurna*, *Marguerites*, *Marigolds*, *Mignonette*, *Narcissuses*, *Pansies*, *Primroses*, *Polyanthuses*, *Pentstemons*, *Primula japonica*, *Pernettyas*, *Polygala Dalmaisiana*, *Papaver Rhæas*, *Petasites fragrans*, *Potentilla reptans*, *P. fragariastrum*, *Roses*, *Ranunculus repens*, *Rhododendrons*, *Silene maritima*, *S. pendula*, *Snowdrops*, *Salvia splendens*, *Spirea Thunbergii*, *Viburnum plicatum*, *Virginian Stock*, *Veronica polita*, *V. officinalis*, *V. Lindleyana*, and several garden varieties, *Vinca*, *Violets*, and *Wallflowers*.—WILLIAM ROBERTS, *Penzance*.

#### EXTRAORDINARY TITHES ON FRUIT AND MARKET GARDENS.

THE following is a copy of the Bill to be introduced by Mr. Inderwick, as referred to by him at recent meetings in Rye and Hastings on the Tithe (Extraordinary Charge).

"Draft of a Bill to amend the Tithe Commutation Acts as to Hop Grounds, Orchards, Fruit Plantations, and Market Gardens.

"Whereas by the Tithe Commutation Acts (described in the schedule to this Act) provision is made for the commutation into a permanent rent-charge of the tithes leviable in the several parishes in England and Wales; but power is given to charge from time to time an additional rent-charge by way of extraordinary charge on Hop grounds, orchards, fruit plantations, and market gardens newly cultivated as such.

"And whereas it is expedient to amend the Tithe Commutation Acts with respect to the extraordinary charges under this power.

"Be it therefore enacted, &c., as follows:—

"1. *No Extraordinary Charge on Grounds Newly Cultivated after Passing of Act.*—An additional rent-charge by way of extraordinary charge shall not be charged under the Tithe Commutation Acts on any Hop ground, orchard, fruit plantation, or market garden, newly cultivated as such, after the passing of this Act.

"2. *Saving for Pending Proceedings.*—Nothing in this Act shall effect or be deemed to apply to any proceedings taken or to be taken in relation to the charging of an additional rent-charge by way of extraordinary charge on any Hop ground, orchard, fruit plantation, or market garden, newly cultivated as such, in any case where an award in that behalf was made and confirmed, or an application in that behalf was made to the Tithe Commissioners before the commencement of the present session of Parliament.

"3. *Redemption of Existing Extraordinary Charge.*—The Tithe Commissioners shall, on the application of the owner of any land charged with an extraordinary rent-charge under the Tithe Commutation Acts, by an order under their hand and seal, direct that rent-charge be redeemed by payment by or on behalf of the owner of the land, within such time as the Commissioners by their order appoint, of a sum of money equal to nine times the amount of the rent-charge.

"4. *Application of Existing Powers to this Act.*—All the powers and provisions of the Tithe Commutation Acts respecting the redemption of rent-charge and the assessment and recovery of redemption money and expenses (except as otherwise by this Act is provided)

shall be applicable to all redemptions authorised and effected under this Act.

"5. *Short Title*.—The Act may be cited as the Tithe (Extraordinary Charge) Act, 1881."

### PLANTS CERTIFICATED IN 1880.

THAT a great demand exists for novelties in the plant world is well shown by the number the principal florists and nurserymen send out annually, for it is evident that a desire to improve the various races of florists' flowers or to add to the species of plants in cultivation would not alone induce the expenditure and labour requisite to effect either of these purposes. There must be a sufficient number among the wealthy who are willing to pay long prices for distinct and handsome novelties, and to this encouragement we owe the additions made every year to our gardens.

To many who were not in the secret it would appear strange that a commercial body of men should send experienced travellers into various parts of the world seeking plants of which comparatively few usually arrive in this country alive, and of those few it is often a matter of chance if there be any of sufficient merit to become of real value; or, on the other hand, that there would be any approximate compensation for the time occupied in obtaining distinct and attractive crosses between plants already in commerce, or in endeavouring to improve existing varieties, in which the failures must necessarily be more numerous than the successes. When it is further considered that immediately a firm sends out a new plant it loses its exclusive right in it, and those that are readily increased soon become so numerous as to reduce the price considerably, it is not surprising the prices at which they are first issued are somewhat high, though certainly not out of proportion to the risks and expenditure incurred in their production: consequently before a plant is distributed as large a stock as possible is raised, and in some cases several years are needed to obtain sufficient for placing in commerce. When, however, that has been accomplished a passport is required to the favour of the horticultural world, and this is furnished by the certificates bestowed upon new plants that are considered to merit them at the chief horticultural exhibitions.

As the gentlemen who officiate as judges on such occasions have usually had the advantage of lengthened experience, it may be fairly expected that those plants they select for these marks of distinction are entitled to them from the beauty of their foliage or flowers, and their distinctness from others already grown. In the majority of cases considerable care and judgment are exercised in making the selection from the large number usually submitted for the honour, and as a result the award of a certificate is a good indication to the public of the value of a plant. Doubts are, however, sometimes expressed as to the taste and knowledge evidenced in certificating certain plants; but as a rule it will be found that those who entertain these doubts have formed their judgment after rapid propagation has deteriorated the quality, for it must be remembered that when exhibited the plants are in the best condition, and they have frequently to be shown several times before the coveted award is gained.

What may be termed the head quarters for exhibitions of new plants are the Royal Horticultural Society's Shows and Committee meetings, and the Royal Botanic Society's Exhibitions at Regent's Park, where some hundreds are annually submitted to the attention of the Judges. During the past year at the two places named no less than 303 certificates were awarded; and as nineteen plants were similarly honoured at both, there was a total of 284 presumably good additions to our list. Of these awards 186 were obtained at Kensington, and 117 at Regent's Park. As usual the three chief metropolitan nurserymen, Messrs. J. Veitch & Sons, Mr. W. Bull, and Mr. B. S. Williams, secured by far the greatest number—namely, a collective total of 130. Messrs. Veitch had eighty-one plants certificated, Mr. Bull twenty-eight, and Mr. Williams twenty-one; fifty-five of the first-named being obtained at Kensington, and of the others five and eight each respectively. Further, Messrs. Veitch had nine of their plants honoured by both Societies, Mr. Bull two, and Mr. Williams five. It will be seen how large a proportion these numbers represent when it is stated that, exclusive of the three firms named, there were fifty-five exhibitors, among whom the remaining 173 certificates were divided, few obtaining more than five each. The numbers given above include the certificates awarded by the National Auricula, Carnation and Picotee, Societies at Kensington, as well as those given by the Societies already mentioned.

All the plants were not, however, recent introductions, although the majority were; but in some cases they have been known in this country for several years, and having been neglected or become scarce are novelties to most growers. Indeed it is a question whether it be more meritorious to introduce a new plant,

or to rescue from obscurity a comparatively old one of real cultural value. Many beautiful plants have this year been brought into notice, and others have had their claims to attention confirmed or duly recognised. Most of these have been fully described in the *Journal of Horticulture*, and all have been referred to at one time or another, but perhaps a brief review of them may be acceptable to some readers. Excluding for the present those known as florists' flowers, the first to be noted are the

**ORCHIDS.**—These have been numerous and well represented, about thirty having been certificated, all meriting the honour, and their most marked characters are indicated in the following cursory descriptions:—*Angraecum Kotschy* (Veitch).—A pretty and interesting species from Zanzibar, with deep green foliage and spikes of pure white wax-like flowers, each with twisted spur about 8 inches in length. A very desirable Orchid. *Barkeria cyclotella* (Bull).—A very charming Orchid from Mexico, with small flowers, the sepals and petals pale rosy pink and a heavy blotch of purplish crimson in the lip. *Bolbophyllum Beccarii* (Henderson).—Very peculiar, and of more botanical interest than cultural value. Leaves of great size, 2 feet long and proportionately broad, with small rather dull flowers possessing a most offensive odour. *Calanthe tricarinata* (Veitch).—A Japanese terrestrial species, with inconspicuous greenish yellow flowers in loose spikes, the lip chocolate-coloured and ridged. It is chiefly remarkable for having proved hardy at Chelsea. One of Mr. Maries' introductions. *C. Marstersonia* (Veitch).—A pretty hybrid between *C. labiata* and *C. Loddigesii*, possessing several characters of both parents. The flowers are about 4 inches in diameter, with rosy sepals and a crisped lip. *Calogyne ocellata maxima* (Williams).—An excellent form of the species, with larger flowers, more distinctly marked, and borne in larger racemes. *Cypripedium Fairieanum* (Veitch).—A somewhat rare species, bearing a resemblance to *C. barbatum*, with flowers of medium size and pretty but not imposing. *C. marmorophyllum* (Veitch).—The result of a cross between *C. Hookerae* and *C. barbatum*, and intermediate in character, possessing the handsome marbled foliage of the former and the flowers of the latter, but darker in colour. *C. Morganianum* (Veitch).—Another hybrid obtained by Mr. Seden, the parents being *C. Stonei* and *C. Veitchii*, both of which it resembles in some points. *Dendrobium splendidissimum* (Veitch).—A beautiful hybrid; still another of Mr. Seden's productions, obtained by crossing *D. macrophyllum* Huttoni and the fragrant *D. heterocarpum*. It partakes of the habit of both, but is near the last-named in the size and form of flowers. The white sepals are tipped with purple, and the lip has a large maroon spot. *Huntleya meleagris* (Veitch).—Not a new introduction, as it has been known in English gardens since 1836. It is, however, peculiar and striking, being suggestive of *Bollea coelestis*; the white marbled brownish flowers are produced from the base of the stem. A South American species. *Lalia elegans prasiata* (Williams).—An excellent form of this beautiful Orchid, the colours being much brighter. *L. Philbrickiana* (Veitch).—A hybrid between *Cattleya Acklandiae* and *Lalia elegans*. It is a handsome form, and quite intermediate between the parents.

*Masdevallia bella* (Bull).—One of the Chimæra section, with the peculiar characteristic tails to the chocolate-coloured sepals, and with a small white lip. *M. tovarensis* (Veitch).—A well-known species from Columbia that has been some years in cultivation. The specimen for which the certificate was obtained was extremely fine, bearing over sixty of its pure white flowers. *M. Wallisi* (Bull).—Like the one mentioned above also related to *M. Chimæra*, the sepals prolonged into tails and closely covered with hairs; lip white. *Microstylis calophylla* (Bull).—A terrestrial Orchid of dwarf habit with pretty foliage, the colour being a bronzy tint, margined with a lighter hue and veined. *M. metallica* (Veitch).—Also of dwarf habit, with dark leaves of a metallic appearance, and spikes of purple flowers. Both species are suited for culture in pans. *Mormodes Wendlandi* (Veitch).—A remarkable species at the last meeting of the Royal Horticultural Society. It has long spikes of pale yellow flowers that are well known to have an extremely peculiar structure as regards their adaptation for cross-fertilisation. It is a South American plant, and has not been long introduced. *Odontoglossum anceps* (Veitch).—This may be regarded in colour and appearance as an improvement on *O. maculatum*, which it slightly resembles. The sepals are reddish chocolate colour; the yellowish flowers are spotted with bright chocolate. *O. blandum* (Veitch).—A dwarf and pretty species, about 9 inches high, with neat small flowers spotted with chocolate or a brownish tint. The lip is white and spotted with purplish violet. A rare Orchid, and rather suggestive of *O. navium*. *O. hystrix serratum* (Lawrence).—A beautiful variety, easily distinguished by the larger flowers, brighter and well-defined markings, and the serrate or indented lip. *O. Roezli superbum* (Low).

—A great improvement on the type, the colours very bright, and the flowers of considerable size. *O. polyxanthum* (Cobb).—In the way of *O. triumphans*, but distinct; colours not quite so bright, and lip fringed. *O. vexillarium splendens* (Veitch).—One of the most handsome varieties of a well-known species. The flowers are very large and of a fine deep rose colour. *Oncidium concolor majus* (Veitch).—An attractive variety and very distinct; the flowers, as the name signifies, being much larger than in the ordinary form. *O. crispum grandiflorum* (Bull).—Very distinct, with larger flowers than in the type, and deeper richer-coloured markings. *Saccolabium denticulatum* (Williams).—A botanical certificate was awarded for this plant at one of the meetings at Kensington. It produces a small spike of white and yellow flowers near the base of the growth. It is interesting botanically.

It will thus be seen that Orchids were abundantly shown last year, and several excellent novelties introduced to growers. —L. C.

(To be continued.)

#### GANSEL'S BERGAMOT PEAR.

MANY old gardeners entertain the opinion that this is the best Pear in cultivation. It is unquestionably a variety of great exee-

lence, the fruit being of imposing appearance and splendid quality. Some Pears have become so popular that there is a slight danger of the merits of some good old varieties being overlooked. We would not that this were one of them, for where a good position against a wall can be afforded Gansel's Bergamot will occupy it worthily. The following notes on this Pear by the author of the "Fruit Manual" may be appropriately introduced here:—"The tree is a shy bearer during the first period of its growth, but when it becomes aged it produces more abundantly, though the fruit is of smaller size. To increase its fruitfulness, it has been recommended to impregnate the flowers with the pollen of some other variety, such as the Autumn Bergamot. It is generally believed that this variety was raised from seed of the Autumn Bergamot by Lieut.-General Gansel at his seat, Donnelland Park, near Colchester, in 1768, and this rests upon a communication to that effect from David Jebb, Esq., of Worcester, nephew of General Gansel, to Mr. Williams of Pitmaston. Mr. Lindley says, 'The Bonne Rouge of the French is evidently of the same sort, and the name must have been given it after its having been received from that country.' I am unwilling that any doubt should arise as to this esteemed favourite being a native fruit; but when I find, by the manuscript catalogue of the Brompton Park Nursery, that both the Bonne Rouge and Brocas'

Fig. 4.—GANSEL'S BERGAMOT PEAR.

Bergamot, which are acknowledged synonyms of Gansel's Bergamot, were cultivated there in 1753, I am inclined to doubt the correctness of the above statement, and as this catalogue is the earliest I have been able to procure of that nursery, it is possible that it was grown there at a much earlier period under both of these names."

#### WINTER VEGETABLES.

JUDGING from the Scotch and English paper reports the mild weather we have experienced here has not been general, but it has been much more favourable than the two last seasons, and if due forethought has been exercised vegetables should be cheap and good for those who have to buy them, and abundant with those who have to supply them for either market or home consumption.

Broccoli are coming in true to their time, as well as fine in size and good in quality. Veitch's Self-protecting has been grand, and, indeed, is so at the present time. Should frost not interfere we shall cut many heads weekly until some time in February. It is an excellent variety, and must be grown wherever Broccoli are required in December. Osborn's variety is showing well and is another we could not well dispense with it.

Carter's Heartwell Marrow Cabbage, the principal heads of which, cut off in September and October, are producing side

sprouts from the roots and stems which were left in the ground, quite equal to the best Coleworts. A "chance sowing" of Cabbage made in July will produce better heads in January than I was able to cut in April or May last. The variety is a new one and named Dickson's (Edinburgh) Redbraes, and I am mistaken if it does not become a great favourite.

Brussels Sprouts have improved more during November and December than they did in August and September last year. This is quite an indispensable winter vegetable, and well worth all the attention possible. Some of our present plants are from seed sown where they are growing, and others were transplanted when small, and I can see no difference between them. Not many years ago selecting Brussels Sprouts was simple, as there were only two or three varieties, but now they are numerous, though it is doubtful if the old varieties have been surpassed.

The Dalkeith and the Dalmeny Savoy are not of very high quality, but they can always be relied on in severe weather, and although they may not be in great demand in the present mild weather, this must not lead to their neglect for another winter. The Drumhead and Green Curled varieties were planted between the Potato rows in July; after that we lost sight of them amongst the Potato haulm for some weeks, but they are easily seen now, as many of the heads are from 12 lbs. to 20 lbs. in weight.

Celery I am not quite pleased with, as it is rather pithy. How this occurs I cannot exactly say, especially as I have had it

fairly good under the same treatment. Season, seed, or situation may have something to do with it, and I shall be glad to have some seed that can be relied on to produce really solid produce.

Parsley is also an important winter crop. Like Carrots I have found it partial to some soils. Many a promising row has died quite away with us before it was half grown. Remembering this I sowed seed more plentifully during the past summer as margins to walks and near the bases of walls, and there are no blanks anywhere. Probably the soot and lime added to the soil at digging may account for this.

Parsnips became a little rusty two months ago, but apart from this they made good growth and keep well. Turnips are growing, and sweet little roots are obtainable. The Lettuce and Endive were covered with frames and lights early in November, and have not kept so well as those left fully exposed. Radishes have kept up a supply. China Rose is the best winter variety.

Although early Potatoes were badly diseased, late varieties are keeping exceptionally well; no disease or decay of any kind is visible amongst them. Seakale, Rhubarb, and Asparagus roots are forcing freely, which leads me to suppose that they must be much better matured than they were during the previous two seasons, and it also makes me hope that this productive maturity will not be confined to vegetable roots alone, but will extend to all fruit trees and vegetation generally in 1881.—J. MUIR, *Margam*.

#### AVERAGES OF RAINFALL AT RANGEMORE GARDENS, BURTON-ON-TRENT.

	Totals for each 14 months for 14 years.	Averages for each 14 months for 14 years.	Monthly Rainfall for 1880.	Totals of each year's Rainfall for 14 years.
January .....	34.23	2.44	0.35	1866—38.30
February .....	27.96	2.00	1.78	1867—32.24
March .....	24.94	1.78	0.64	1868—31.70
April .....	28.31	2.02	0.89	1869—31.78
May .....	29.95	2.14	1.80	1870—24.25
June .....	39.97	2.85	2.87	1871—31.79
July .....	38.47	2.75	6.67	1872—48.72
August .....	52.66	3.76	1.51	1873—27.74
September .....	47.60	3.40	3.68	1874—22.45
October .....	46.30	3.31	4.19	1875—31.32
November .....	32.88	2.35	1.65	1876—29.91
December .....	37.46	2.67	3.47	1877—31.70
				1878—29.54
				1879—27.38

Average of first six months rainfall for fourteen years, 13.24 inches; second six months, 18.24 inches; average of yearly totals for fourteen years, 31.47 inches. Total rainfall for first six months of 1880, 8.33 inches; second six months, 21.17 inches. Yearly total, 29.50 inches. Total rainfall in fourteen years, 440.73 inches.

#### VICK'S CRITERION TOMATO.

DURING a recent visit to Norris Green I was much interested with a specimen of Vick's Criterion Tomato growing amongst other varieties in one of the houses there, and it is evident that whatever may be written or said about the true variety, it is nevertheless a fact that fruits can be gathered from the same plant and exhibited as distinct varieties without much fear of disqualification. The plant in question was bearing ripe fruits, those on the lower part of the stem being smooth as an egg, while those on the upper portion were distinctly corrugated and might easily be taken for another variety. Mr. Bardney thinks it probable that by cuttings the true characteristics of the variety may be maintained. The variations and peculiarities in the formation of Tomatoes, however, are not confined to Criterion; Trophy and Stamfordian, for example, are both subject to the same eccentricities, and convey the idea that it would be difficult for judges to disqualify a dish of Tomatoes because they are not the true variety.

I was more than repaid for my walk of five miles to visit these gardens by the many excellent examples of cultivation I saw there. Richardias were very numerous and in the finest possible condition. Calanthes tastefully arranged with Cypripediums and other choice plants had a very pleasing effect in the house devoted to them. Eucharises are well grown, one bulb in a 5-inch pot, and are remarkable for their health and vigour; a succession of these plants is maintained, and they are found valuable for room decoration. Tea Roses are very numerous and in good condition, and Poinsettia pulcherrima is well represented

by dwarf sturdy examples. The same may be said of Euphorbia jacquiniæflora. In the conservatory, amongst many plants that are bright and beautiful, *Luculia gratissima* reigns supreme. It is planted-out in a border and permitted to grow freely; it is flowering at every point, and its fragrance and immense trusses commend it to all who have the convenience for planting it out.

Every branch of gardening undertaken at Norris Green appears to be thoroughly carried out, and it is evident that Mr. Bardney is a sound believer in the proverb "Practise what you preach."—A. R. COX, *Elm Hall, Wavertree*.

THE inventor of the celebrated Gishurst compound has devised another substance that is likely to be of benefit to gardeners and others who are engaged on land and in woods. The substance in question is named GISHURSTINE, and is manufactured by Price's Patent Candle Company. It is an application for strong boots, and an excellent one. We have found that it softens hard leather and renders it impervious to water, while it is quite devoid of any unpleasant smell that renders so many kinds of "dubbings" disagreeable. We have also the following testimony from a gardener to whom we supplied a portion of the new substance:—"I have given the 'Gishurstine' a fair trial and can confidently recommend it. It was applied at intervals of a few days to a heavy pair of boots; the result being the very thick tops are gradually softening and becoming impervious to water. Well rubbed in before the fire, the dubbing is absorbed by the leather, and does not in the least interfere with the usual polishing. I should think the Gishurstine will prove a boon to gardeners, especially to those who are constantly using water." It will be equally valuable to sportsmen, farmers, and game-keepers.

— MR. ANDREW CAMPBELL of Ashford Gardens, writing to us on the DEFICIENCY OF HOLLY BERRIES in Ireland, observes:—"I have never seen the Holly so devoid of berries as it is this winter, and I learn from other parts of the country that none was left to brighten the Christmas decorations. Here there were numbers of berries in October, but at the end of the first week in November there was none to be seen. I think the sudden disappearance of the berries may be accounted for by the unusual number of blackbirds I see here this winter."

— THE same correspondent describes the TEA ROSE MADAME LAMBARD as one of the best for constant blooming out of doors. A plant growing trained to an east wall commenced blooming last May and continues to this date, the blooms being of remarkably fine quality. The best blooms were cut December 16th and 21st. Those were all that could be desired in size, form, and colour, and he considers this Rose worthy of extensive cultivation on account of its superior late-blooming qualities.

— MANY of our readers will regret to learn that the well-known floriculturist, MR. ANTHONY PARSONS, died on Christmas day at the age of seventy years. His skill as a horticulturist and the many new varieties of florists' flowers he has succeeded in raising have rendered his name well known in the gardening world. At the time of his death he was gardener to Captain Blake, Danesbury, Welwyn, Herts, where he had creditably fulfilled his duties in that position for nearly thirty years. It will be remembered that he was also member of the Floral Committee of the Royal Horticultural Society for several years, and frequently judged at the most important exhibitions held near the metropolis.

— WE are informed that the Annual Dinner of the HORTICULTURAL CLUB will take place at the Club House on Tuesday next the 11th inst., John Lee, Esq., in the chair. We are pleased to hear that the Club is prospering, many new members having joined during the past year.

— WE are informed by Mr. D. Thomson that the YEAR 1880 was the driest on record at Drumlanrig, Dumfriesshire, the total rainfall being only 33.1 inches, and 15 inches below the average of twenty-two years.

— RESPECTING the WEATHER IN NORTHUMBERLAND, Mr. E. Fister, The Gardens, Blenkinsopp Hall, writes as follows:—"Snow fell here on the 28th ult., but the weather appears to have changed, and we are more likely to have rain. Until the date mentioned we had dry weather with frequent frosts. During October frosts occurred on three days, the lowest temperature being 19° Fahr.; in November on fourteen days, the lowest being 10°; in December nine days, the lowest 17°."

— WE have been favoured with a sight of advance sheets of a NEW WORK ON HORTICULTURAL BUILDINGS by Mr. F. A. Fawkes. This will be of a very comprehensive character, and the subject will be treated in a way which has not hitherto been attempted. We shall merely mention a few of the heads, so as to give some idea of the manner in which the author intends to produce the work. We find such heads as "Astronomical" in reference to the Sun's Orbit, the Sun's Rays, Plant Life, Light Rays, Heat Rays, and Chemical Rays. Then the more practical work is treated upon—Inclination of Roofs, Transmission of Solar Rays, Aspect and Site, Levelling, Drainage, &c. The work will be ready in about a month, and will be entitled—*Horticultural Buildings; their Construction, Heating, Interior Fittings, &c., with Notes on some of the Principles Involved.*

— WE clip the following EXTRAORDINARY ADVERTISEMENT from the *Launceston Examiner* (Tasmania), of October 20th, 1880:—"NOTICE.—The undersigned having the largest and best stock of stove and greenhouse plants in Tasmania, for which he has paid cash for some four times their weight in gold. New and rare seeds I pay yearly to J. Carter & Co., London, the largest seed firm in the world, four times their weight in gold, from whom other seeds and plants are on the way from England. Being in debt I will not refuse any reasonable offer.—J. ALLEN, *Florist, Longford.*"

— MESSRS. J. VEITCH & SONS, Chelsea, announce that "A MANUAL OF THE CONIFERÆ" is in preparation, and will be published in March. It will be fully illustrated, and contain a general review of the natural order, a synopsis of the genera, species, and varieties suitable for the climate of Great Britain, and the culture of Coniferæ. That much valuable instruction will be given under each head we have no doubt, and the work is likely to prove one of considerable general utility.

— MR. J. M. COVENTRY, lately with Messrs. Waite, Burnell, Huggins, & Co., has commenced business as seedsman and florist at 111, Gray's Inn Road, London, W.C.

— DURING the ensuing year Messrs. Sutton & Sons will offer a large number of SPECIAL PRIZES FOR VEGETABLES, MELONS, AND CUCUMBERS at some of the chief horticultural exhibitions. At the Royal Horticultural Society's shows and meetings the most important will be the following—On June the 3rd nine prizes, including two first prizes of £3 3s. or a silver medal and £5 5s. or a gold medal, the latter for Melons and Cucumbers. On June the 28th six prizes, with a first of £6 6s. or gold medal. On August the 5th and on November the 8th twenty-five prizes, including a £5 5s. first. At Manchester on August the 24th nine

prizes will be offered, with one of £5 5s. At the International Potato Exhibition twenty-two prizes, the chief being £7 7s. Messrs. Dickson, Brown, & Tait will also offer nine special prizes for Cauliflowers, Tomatoes, and Melons at the Manchester Exhibition in August.

— *Nature* has the following communication from one of its correspondents relative to the MOVEMENTS OF LEAVES:—"A year ago we had in our conservatory a healthy young plant of *Acacia mollissima*. It bore no flowers, but consisted of a simple axis adorned with the soft feathery leaves of its genus, which closed up at night. Our gardener, however, thought it would improve in appearance if it could be made to bear a few branches, and with that view he cut it back. His end was achieved: a new stem shot up from the section, and graceful limbs were thrown out in turn by it. But along with this a strange result followed: the fresh leaves borne by the new stem and by the branches now closed at night, while the old leaves below the section ceased to do so. These lower leaves have long since fallen off, but the upper ones kept to their habit, and at the present time all fold up at dusk save a few of the very oldest, which only partially shut, or, in one case, do not shut at all."

— THE *Scientific American* has the following in reference to A NEW OIL FROM GRAPE STONES:—"M. T. Fleury of Bordeaux, France, has explained the method by which a very valuable oil is obtained from the kernels of the Grape. The refuse left after distilling brandy or making verdigris is dried and ground fine in an ordinary mill, the yield of oil being in direct proportion to the fineness of the grinding. Some manufacturers first press without heat, obtaining about 5 per cent. of oil; afterwards the stuff is heated and pressed, with a yield of 10 or 15 per cent. more oil. The oil is of a light yellow colour, and in course of time obtains a density of 0.9202, at 59° Fahrenheit, and solidifies at about 3° Fahrenheit. Although it does not congeal so soon as other oils it becomes rancid and viscid when exposed to air, and, although it saponifies readily, the soap produced lacks hardness and density. Black Grapes contain much more oil than white Grapes, and the kernels of Grapes from Vines in full vigour yield more oil than those from very young or very old Vines. Generally black Grapes give from 15 to 18 per cent. of oil, white Grapes 10 to 14 per cent. It is probable that American Vines, especially those of California, yield more oil than French Vines. In the south of France 25 lbs. of kernels are allowed for 25 gallons of wine. It is easy to estimate the quantity of oil that is annually lost in Grape-producing countries. The extraction of oil from Grape kernels is by no means new. M. Fleury says that in 1800 there was a Grape oil factory at Olby which had been long in operation. Bergamo, Italy, produced the oil in 1770, and Rome and the vicinity of Aneona before 1782. It was also made in Naples on a commercial scale in 1818, and in Germany before 1787. The oil is sweeter than nut oil, and remains fluid at a lower temperature. When burned in lamps it gives a bright, smokeless, and odourless flame."

#### FLORISTS' FLOWERS.

IN commencing with the new year a series of seasonable notes on florists' flowers it may be well to take a retrospect of the past and ask this question, Are not florists' flowers faster gaining popularity than formerly? We answer in the affirmative. The prominence with which certain societies have during the past few years brought them before the general public is doing much to popularise them. The Auricula, Carnation, Chrysanthemum, Dahlia, Pansy, Pelargonium, and Rose Societies are all engaged in the same worthy object—the improvement and encouragement of an art that offers repose to many whose daily occupations are not perhaps amongst flowers. Where a few years since florists' flowers were almost unknown collections are now grown. Again, let us compare the Rose, Pelargonium, or Chrysanthemum of the

present day with the standard of excellence of twenty years ago, and note the rapid stride made in form, symmetry, size, and richness of colouring. Nor can it be said that we have attained the limit of improvement, for every year new and improved varieties are introduced by enthusiasts, showing how great is the field in which florists labour.

**AURICULAS.**—These are not attractive now, except so far as regards prominent hearts and stout clean foliage, which the florist always admires. To keep the plants in the best condition remove the lights from the frames on all mild and favourable occasions; but if frost sets in with any severity cover the glass every evening with mats or other suitable covering. A frequent examination is necessary, removing all dead or decaying leaves, and care must be taken that the plants do not suffer from a superabundance of moisture. If the soil in the pots is very dry select a mild day for supplying water, which must be done carefully without wetting the foliage. If the soil in the pots is not wet, and at the same time the foliage of the plants is dry, a smart frost will not injure Auriculas. Employ protection, therefore, intelligently, and do not let it degenerate into "coddling."

**CARNATIONS AND PICOTEEES.**—The chief attractiveness of the plants now consists in their cleanliness and health. The true florist sees beauty in his plants at all seasons when they are in satisfactory condition. He knows that to have beautiful flowers in July the plants must not be neglected in January. Slugs, worms, undisturbed decaying foliage, with a close and damp atmosphere, are their natural enemies, and must be guarded against assiduously. The same care in watering and ventilating is requisite as in the case of Auriculas in frames, and if the soil in the pots becomes close and there is the slightest signs of moss or weeds, an occasional stirring with a pointed stick, cleaning the plants at the same time, will be of great benefit. Plants in beds must also have attention; mulching the surface of the soil with cocoa-nut fibre refuse prevents injury both by frost and slugs. For rich and poor, town and country, few flowers are more suitable than those under notice, and none better repay for the attentive care of the cultivator.

**CHRYSANTHEMUMS.**—Cuttings of these may during this month be inserted in numbers proportionate to the demand, or as the old stools may produce them. Some varieties start much more readily than others; in fact, some of the Japanese varieties are very shy indeed in producing cuttings. The best means of increasing them is undoubtedly by the suckers that arise from the base of the plants. These may be taken off, and inserted either singly in small pots, or by placing several in the same pot and potting them off singly when rooted. If inserted now and placed in any structure where frost can be excluded they will strike readily. Those that are intended for specimen plants may be encouraged by a little warmth, so that the foundation of a plant may be laid as quickly as possible.

**HYACINTHS AND TULIPS.**—Either of these intended for exhibition about the middle or end of March next will require to be taken from under the covering of cocoa-nut fibre and coal ashes, where they have been placed during the past two months. Gradually inure them to the light. A good plan is to place a small pot over each crown for a few days, when they may be removed, the hole in the pot admitting light enough to gradually harden them. If the soil is dry water may be given on removal. Place the plants in a position near the glass in a cool greenhouse, and they will be found to advance very steadily. If some of the varieties are required to bloom earlier they can be placed in a warmer house; and if they are required late in the season—about April, they should at once be arranged in a cold north house or frame and retarded in their present stage, which will be found much easier than when the days are longer and the mean temperature higher. To keep them under covering in the dark after the second week in January would prove injurious.

**ROSES.**—Those in beds that have not been surfaced with manure should have that attention without further delay, as the manure not only protects the base of the plant from injury by frost but greatly benefits the roots. All vacancies should be filled as rapidly as possible, and all necessary staking and relabelling be completed at once. Climbers on walls must be nailed in and regulated, and the soil renovated around their roots.

**Roses in Pots.**—The first batch will be starting freely. Syringe them on all fine days to keep green fly in check. Prepare other plants by pruning and training to give a succession. Before pruning allow the plants to become moderately dry, then cut away all slender growths, and turn the points of the shoots towards the rim of the pots, and secure them in this position by means of string. This will check the rise of sap and make a dense dwarf-habited plant, instead of allowing two or three breaks to develop from the top to the detriment of the lower part of the plants.

Introduce them gradually to about 60° of heat. Plants of *Maréchal Niel* in cold houses are commencing growing, and may be regulated and the ravages of green fly guarded against.—A FLORIST.

### HORTICULTURAL EXHIBITIONS.

In taking a retrospective view of the flower shows in the past season it must be generally acknowledged that the gardeners of this country deserve great praise and encouragement for the skill and energy displayed in the high quality of their productions in fruit, flowers, and decorative plants. These have called forth the admiration of large numbers of visitors, and those who have not seen them have read with pleasure the published reports. I have no doubt many persons visiting those shows and hearing that prizes are offered in various classes believe those prizes to be of great value, highly compensating the exhibitors, and that growing plants for the shows is very remunerative. Now, if those who derive so much pleasure from a visit to such exhibitions were properly informed on the subject their generosity would, I think, be awakened, and they would unite in subscribing to give prizes that would fairly compensate the competitors, and would render the already beautiful displays still more admirable; indeed this is a subject of such national importance that it has a claim upon the public purse, for no money can be better expended than in encouraging a love for flowers. Many of the general public will, however, be surprised to hear, that though so much trouble and expense are necessitated in producing these excellent examples of cultivation, even growers who are fortunate in obtaining a prize often receive less money value than the expense of the carriage of the plants to the exhibition, and those who do not secure a prize are great losers. No well-thinking person can desire such a state of things as this, therefore all who have a love for the beautiful should subscribe freely to encourage local as well as metropolitan flower shows.

Enormous sums are subscribed for competitions, which have a baneful effect upon the community, and yet that which is most beneficial receives comparatively meagre support. It would at least be only just that all persons who bring plants and are not fortunate in obtaining a prize should be reimbursed their expenses. This would encourage many more to compete and add to the attractions of the show, and it will be generally found that the visitors will average in proportion to the attraction.—R. C.

### LÆLIAS IN WINTER.

THE genus *Lælia* comprises numerous species and varieties, all possessing considerable attractions and usually occupying an important position where either large or small collections of Orchids are grown. The delicacy or intense richness of the colours that distinguish the flowers, their elegant forms, and the very slight difficulty attending the culture of the majority of the species, render *Lælias* general favourites. Further valuable characters and recommendations are derived from the diverse seasons at which they bloom, for with the exception of a few months a supply of bright flowers is maintained throughout the year. Summer, autumn, and winter have each their characteristic species, all handsome and well meriting attention, but, as was remarked of the *Zygopetalums* last week, those that flower at the present time seem especially attractive, and a few observations concerning their respective qualities will be seasonable.

*Lælias* are epiphytal Orchids confined to the American continent, and chiefly abounding in Brazil and Mexico. They are very nearly allied to *Cattleyas*, and to casual observation they are not distinguishable, however botanists have decreed the possession of eight pollen masses sufficient to separate them as a genus from *Cattleyas*, which have only four. In habit, form of the flowers, colours, and beauty the two genera approach each other closely. Although the subjects of these remarks are all epiphytal in habit, yet several are cultivated in pots, the species of strongest growth being best suited for that mode of culture, the others requiring blocks. As regards temperature the majority need similar treatment to *Cattleyas*, but several, especially the Mexican forms, thrive best in a cooler house. For those grown in pots the usual compost of peat, sphagnum, and charcoal is suited, the drainage being abundant, and the supply of water liberal during the growth of the plants. These remarks are applicable to the whole genus, but especially to the winter-flowering *Lælias*, of which the most remarkable are briefly described in the following notes.

***Lælia anceps.***—A Mexican species of great beauty, that flowers during the dull season, and remains in good condition for a considerable time. It is extremely variable in colours and form of the flowers, but in the type these have broader petals than sepals,

both of a fine rosy hue, and a long lip blotched with purplish crimson towards the apex. The flowers are borne on the upper portion of a spike, which is frequently 18 inches in length. The plant is of robust growth and blooms freely, succeeding admirably

in pots. Of the numerous varieties, which vary principally in the colours of sepals, petals, and lip, the three following deserve special mention :—

*L. anceps* var. *Barkeriana*.—One of the most elegant forms, as

Fig. 5.—*LÆLIA ANCEPS* VAR. *BARKERIANA*.

the annexed engraving well indicates, and easily distinguished by the sepals and petals being of equal width. They are of a delicate rosy tint, the lip being broadly margined with intense purplish

crimson, and streaked inside with a similar hue ; in form it is also longer and much more acute than in the type. It was, like the species, found in Mexico, and was named in honour of George

Barker, Esq., of Birmingham, in whose collection it first flowered about forty years ago.

*L. anceps* var. *alba*.—A beautiful companion for the one last described, which Mr. W. Bull of Chelsea has placed in commerce. It is a native of Mexico, where it has been found at elevations of 8000 feet above sea level, and consequently is admirably adapted for culture in cool houses. The flowers are pure white, the lip only having a few yellow streaks, which serve to more clearly show the chasteness of the other portion of the flower. It is a charming variety, and cannot be too highly recommended.

*L. anceps Dawsoni*.—Another pretty variety that flowered in the celebrated Meadowbank collection about thirteen years ago, after the proprietor of which it is named. It has white sepals and petals, but the lip is streaked and blotched with crimson and purple, the lip undulated and margined with white. When in good condition the contrast is very striking.

*L. acuminata*.—This species, also from Mexico, is grown both in pots and on blocks, but it succeeds much more satisfactorily under the latter mode of culture. The seape is slender and arching, bearing near its extremity several flowers of moderate size, the sepals and petals of which are white, of a wax-like texture; the lip also white, with a rich bright purple blotch at the base, imparting a very distinctive appearance to the flower.

*L. superbiens*.—Remarkable for its strong growth and the great length the spike attains, frequently exceeding 4 feet, and bearing a dozen or more flowers on the upper portion. The blooms are large, 3 to 4 inches in diameter, with rose-coloured sepals, the petals shaded with darker tints, and the crimson labellum streaked with yellow. It is one of the most handsome in the genus, and requires culture in pots and moderately cool treatment.

*L. albida*.—A neat and attractive species, compact in habit, with spikes 6 to 8 inches long. Flowers of medium size; sepals and petals white; lip pale crimson streaked with yellow. Succeeds on a block in a cool temperature.

*L. autumnalis*.—This usually flowers as late as December or January, and, like the last-named species, requires to be grown on a block. The flowers are large, the sepals and petals purplish with a yellow streaked lip. It varies considerably in the richness of the colouring, several well-marked varieties being known.

In several collections of Orchids most of the above may be found in flower together, but *L. anceps* and its varieties are now particularly attractive.—L. C.

#### HEATING BUILDINGS.

HAVING carefully perused your notice of Messrs. Weeks & Co.'s new mode of heating buildings, I am desirous with your permission to state that the system described and illustrated in the last issue of your valuable medium for discussion and investigation, the *Journal of Horticulture*, is an adaptation of Tobin's ventilating tube and Taylor's patent warming and ventilating system; both in their way as nearly as possible perfect in their aim and action.

As many of your readers may not understand the nature of these inventions, permit me to explain that the former is an air-shaft or chamber with a valve to open or close at the top, which is about 5 feet from the floor. This air-shaft may be plain or ornamental, and may be fixed in or against an external wall by preference, or may be placed in any other convenient position in the apartment, so that an air-duet can pass from the outside of the building and be connected with its lowest extremity for the purpose of admitting a constant supply of pure air. Messrs. Weeks' air-chamber in wall and air-duet through wall communicating with it at its lowest extremity, is identical with Tobin's tube. Taylor's patent warming and ventilating system is obtained by placing the hot-water pipes in cases or air-chambers having an air-duet passing from the outside of building to the end if horizontal, or lowest extremity if vertical; and an orifice of a proportionate size at the other end, or upper extremity of such casing or chamber, the pipes being so arranged that the pure cold air in its passage through the chamber plays upon their entire surface, and so becomes thoroughly warmed before passing into combination with the air of the apartment. This system is automatic in its action, for the hotter the apartment becomes the greater is the inrush of cold air over the pipes, and *vice versa*. As to the position of their coil of pipes under the windows, I can only say that Messrs. Weeks could not have chosen a worse, for if the fresh air requires cooling by passing the glass, why go to the expense and trouble of warming it?—F. W. FLETCHER, 13, Great George Street, Westminster.

THE CHARLEVILLE GRAPES.—Referring to the paragraph

under the above heading in your last week's issue, I beg to say that, owing to misprint of a figure in the local journal from which you quote, there is an error as to the weight of the bunch of Grapes exhibited by Mr. Roberts at this Society's late Winter Show. The exact weight of the bunch was 21 lbs. 6 ozs., not 26 lbs. 6 ozs.—A. BALFE, *Secretary of the Royal Horticultural Society of Ireland*.

#### INSECT HAUNTS.

I HAVE frequently read and heard lately that insects have become more plentiful in our gardens in recent years than they were previously. I think this is true, and it suggests that either the many insecticides which have been introduced during the last twelve years have not been so efficient as was stated, or they have not been promptly and properly applied, for both out of doors and under glass insects keep up their numbers. This should hardly be the case in modern glass houses, as these certainly do not afford so many harbours as the old heavy timber erections; but I think if a little more attention were paid to the subject of insect haunts we might probably have fewer enemies to contend with.

Under glass few pests are more trouble or worse to exterminate than mealy bug. I keep a few in a vinery here I might almost say to experiment on with new insecticides, as I never miss a chance of trying the effects of a new introduction. This time we must have nearly exterminated the insects, as we have given them a strong application, not of our "own" concoction, but of all the others together, and at the same time we have been more careful in clearing out and closing up their harbours than formerly.

I find one of the very worst of these is just on that part where the wood is cut in pruning. Hard well-grown Vine wood does not show any indenture when newly cut, but before the bunches are well formed the pith in the centre of the wood has drawn in and left one of the finest harbours for bug. It is there they congregate during the growing, and defy all means to get them out. I proved this when the Vines were growing last summer, and I was reminded of it again this pruning time, as, although few bugs could be seen in the stems, they were crowded-in to the pith of last year's wood. I have been very careful to cut all these knobs off; and wherever a cut has been made, either in removing old wood or pruning new, the wound has been immediately sealed up with Thomson's styptic. I know this is beneficial in preventing Vines bleeding, but its worth is doubled when it keeps bug out of such harbours. Some say, Wash the glass and woodwork; but my opinion is that mealy bug will not harbour in dead wood if fresh material is at hand, and if the insects are cleared off and shut out from the Vines there would be less difficulty in eradicating them from other parts.

At the bottom of the stem, especially if there is any roughness, is another favourite resort of theirs, and this does not apply to Vines, but to plants in pots as well. In cleaning the latter the leaves only are frequently sponged, but it is at the axils the insects harbour most. Broken rough ends about Peach, Fig, and other trees and plants under glass afford similar harbours, as do also trees in the open garden. If the precaution is taken to cut the wood clean there will not be so much chance of their finding suitable quarters.

Old garden walls, with the joints between the bricks and stones looking as if a flood had washed the mortar from them, are shelters for snails, woodlice, and many others, and rarely can uninjured fruit be gathered from trees against such a position. Too much refuse is frequently allowed to accumulate in kitchen gardens to the encouragement of slugs, snails, and other destructive insects. It is generally the practice to attempt the destruction of insects only when the young vegetables appear above ground; but if gardens were well dusted with lime in winter many insects would be destroyed, the progeny of which would otherwise be a source of great annoyance in spring. I am a little ignorant as to the position of the winter haunts of wasps; but perhaps some of your readers will inform me on this point.—A KITCHEN GARDENER.

#### ROOT-PRUNING AND SUMMER-PRUNING FRUIT TREES.—No. 3.

THE system of summer-pruning by many gardeners of the present day is very different in some respects from that of old practitioners. When I first entered the garden I was given to understand that the shoots on wall or pyramid fruit trees should not be interfered with until midsummer, the reason being that they would shoot again from the lower buds if stopped earlier in the season. At that time the operation was commenced in earnest,

and the shoots on the upper half of the tree were all cut-in to about four or six leaves from the base. The shoots were not removed until a fortnight after from the lower portion of the trees, so that they should not receive too great a check at one time. Many thoughtful men of the present day are acting differently in this respect; but while we differ from the old school on many points we shall still do well not to quite lose sight of our forefathers' teachings.

I will now say something on the present practice. As soon as the trees have made shoots with four or five leaves they should be examined, and the points of the strongest must be pinched out. This will throw more strength into those remaining, so that in a fortnight or so these may be shortened in a similar manner. After this they will produce two shoots; these may be reduced to one leaf from their base. By adopting this system the trees do not receive a severe check at any time of the year, and they will produce strong healthy foliage, fully exposed to sun and air; and the fruit, receiving the same benefit, will be of a much brighter colour and far better flavoured than fruit that has been much shaded and then fully exposed.

I would advise all those adopting this system of pruning to leave the terminal shoot of each branch untouched until the autumn, as the season passed through will teach the cultivator how much it is necessary to reduce these shoots. In addition the sap is kept in regular motion if the points are not interfered with; but this would not be the case if they were shortened early in the season, except with a very vigorous shoot, which should be stopped, and so maintain as evenly balanced a tree as possible.

If time can be given to carry out the above instructions there will be little need to send a man to prune and nail trees on walls when he can hardly hold knife or hammer, and he could do double the amount of work in warmer weather. I do not include the pruning of the Peach in the above, as I referred to that in previous papers, so it will not be necessary to say more respecting it now.

In conclusion, I may say if too vigorous trees are carefully root-pruned and the branches attended to as advised, and with favourable weather, we shall be well repaid for the time and labour bestowed on them.—ROBT. D. LONG.

### MARTYNIAS.

MANY cultivators of annuals are familiar with the beauty of at least one species of this genus—namely, *M. fragrans*, which is undoubtedly the most attractive and best adapted for growing in gardens. Either in pots or borders during the summer it produces its rich crimson-purple flowers freely, which are rendered additionally pleasing by their powerful and agreeable fragrance. To obtain it in good condition outside the seeds should either be sown in a rich light warm border about April, or earlier in a frame, in the latter case potting off the young plants singly, hardening, and finally transferring them to the border. Both methods give satisfactory results, but it is sometimes found advantageous to immerse the seeds in warm water for a short

period previous to sowing, as they are otherwise rather liable to remain dormant for a long time, or to germinate irregularly. Some of the plants may be retained in pots for the greenhouse or conservatory.

Several other species of *Martynia* are known, but they are inferior in beauty to the one described, though perhaps they are more remarkable for their peculiar seed vessels. *M. lutea*, for instance, has dense spikes of orange-yellow flowers with crimson spots, and is occasionally seen in good condition in greenhouses, but the fruit as shown in the annexed cut is strangely formed. All the species are characterised by this peculiarity, though in some it is much more strongly marked than in others. It is of rough woody texture, terminating at first in one prolongation, which as the fruit ripens

Fig. 6.—*Martynia lutea* (fruit).

separates into two curved hornlike appendages, frequently 6 inches in length, that prove highly obnoxious to travellers in the portions of America where it abounds. I have in my possession a fruit which exceeds 9 inches in length, the "horns" being quite hard and sharp as spines.

Other forms are *M. proboscidea* and *M. triloba*, not very attractive in their flowers, but peculiar in their fruits; the last-named is also known as "*Unguis Diaboli*," a very significant title. *M. di-*

*andra* is occasionally grown, but it is not so free in flowering as *M. fragrans*.—R. L.

### KITCHEN GARDEN.

WITH the unusually fine weather in autumn and early winter all outside operations should be in a forward state, but when from unavoidable circumstances such is not the case, no time must be lost in turning up all vacant spaces, so as to give the full advantage of frost in pulverising the soil previously to planting. This is very necessary in strong soil, and if neglected now it adds considerably to the difficulty of sowing or planting. As opportunity offers, the present is a good time to examine the stakes required for Peas and runner Beans, having them sharpened and dressed ready for use. Take up and place under cover any early Broccoli, such as Veitch's Autumn and Snow's Winter, of which, with Cauliflower in pits, a supply will be maintained for some time yet.

### FRUIT HOUSES.

*Pines*.—The progress of plants generally after potting depends much on the condition of the materials employed at the time of potting, hence the importance of attending to these matters previously, so that everything will be in readiness at the time it is wanted—usually in March. The necessary quantity of soil should be placed where it will be moderately dry without becoming extremely so, but it must not be broken up until just before it is needed for potting, as only the fibrous part of the loam is required. Give careful attention to suckers which are to be started soon; and as these are obtained chiefly from winter-fruiting plants, they should, if possible, remain on the stools until required for potting. The night temperature for fruiters and for plants which are about showing fruit should range from 60° to 65° at night, and 65° to 70° by day from fire heat, and 75° to 80° from sun heat; and whenever circumstances permit ventilate slightly, and take advantage of every opportunity to close with a little sun heat, sprinkling available surfaces about the house.

*Vines*.—Great care is now needed in ventilating early houses, neither admitting currents of cold air nor neglecting to ventilate when requisite, to prevent the temperature rising too highly. Commence ventilation early, increasing it as the temperature rises, and when the maximum is reached the ventilation should be gradually reduced, and close the house early. Disbud and tie down the shoots before they touch the glass. In stopping do not be particular about the number of eyes beyond the bunch, but allow the wood to extend sufficiently to insure plenty of well-developed foliage. Overcrowding the foliage is, however, very injurious. Superfluous bunches should be removed as soon as the most promising can be selected. Avoid overcropping, and keep the house a little warmer and drier as the flowers open. Maintain the heat in the fermenting material, keeping a good heap of Oak leaves and stable dung in the reserve ground from which supplies may be obtained.

*Cucumbers*.—Continue a temperature of 70° to 75° in the day, and 65° at night, falling to 60° on cold mornings. Ventilate at the top of the house at 75°, and allow an advance from sun heat to 80° or 85°; but instead of admitting cold air it is better to allow the temperature to advance a little. Examine plants in bearing twice a week, removing weakly and exhausted growths, reserving as much of the young bearing wood as will maintain a suitable equilibrium between the foliage and roots, remembering that nothing is so unprofitable as crowding. Stop the shoots one or two joints beyond the fruit, being guided in this matter by the vigour of the plants. Dust a little sulphur over the foliage and pipes to arrest the progress of red spider and mildew, and upon the first appearance of canker press quicklime well into the affected parts. Young plants should not be allowed to bear too soon, and must not on any account be overcropped. Remove the staminate blossoms as they appear. The floors should be damped

at about 8 A.M. and 2 P.M., and again at 7 to 8 P.M., when the weather is severe and large fires are maintained. Sow seed now to obtain plants for pits and frames heated by fermenting materials. Where no better means exist of raising the plants a bed should at once be made up of equal parts leaves and stable litter thrown into a heap, turned over a few times, and damped to secure fermentation. A bed large enough to hold a one-light box will be sufficient, and a few inches of partially decayed leaves or tan placed in the frame will be suitable for plunging in, and tend to prevent injury by the escape of rank steam, which should, however, be guarded against by a timely preparation of the material. Thus early it is advisable to sow the seeds in 4-inch pots half filled with light rich soil, and as the plants advance in growth place more soil round the stems, which will prevent the check consequent on potting-off singly. A similar bed will also be necessary for raising plants of Melons for a first crop.

*Melons.*—Sow seed at once for the first crop. The seeds may either be sown singly in 3-inch pots, or a dozen seeds be placed in a 6-inch pot, the plants produced to be afterwards placed singly in 3-inch pots. In either case the pots should only be about two-thirds filled with soil, covering the seed about half an inch deep and placing them in a bottom heat of 80° to 85°, and a top heat of 70°. A compost of equal parts of turfy loam and leaf soil with a sprinkling of sharp sand pressed gently down will form a porous compost for the young rootlets, good drainage being essential. For early sowing it is desirable to employ such varieties as come quickly to maturity, among which may be named Davenham Early, green-flesh; and Blenheim Orange, scarlet-flesh.

*Peaches and Nectarines.*—In the earliest forced house the trees will now be in flower, and should have a night temperature of 50° to 55°, the latter not being exceeded on dull days, or very slightly, ventilating above that temperature, and allow an advance from sun heat to 65° or more, with free ventilation. In the driest and warmest part of the day artificial impregnation must be effected by distributing the pollen—shaking the trees if on a trellis, or with a camel's-hair brush or feather gently place the pollen on the stigma. Do not syringe the trees whilst they are in blossom, but the floors and borders may be damped in the morning and afternoon. See that the inside borders are sufficiently moist, and that the outside borders are protected with litter. Trees intended to afford ripe fruit early in June, which have had a rest of several weeks, should be syringed morning and afternoon until well advanced, when it must be discontinued, and damping the border instead in the morning and afternoon; 50° should be the temperature by day and 40° at night artificially. Ventilate freely from 50°, allowing an advance of 10° to 15° from sun heat. All trees in late succession houses should be pruned, dressed, and secured to the trellis. Top-dressing or renewal of the inside border with fresh loam must not be delayed. Any operation respecting the roots is best performed when the leaves are mature, and certainly ought to be done before growth commences. Ventilate as freely as possible so as to retard the swelling of the buds.

#### PLANT HOUSES.

*Store.*—At the commencement of the new year it will be necessary to start a few plants for early flowering. Allamandas that have been well matured and dormant have the wood hard and ripe. A. Hendersoni and Chelsoni are the best for early flowering, except A. nerifolia, which, perhaps, flowers the most freely of all, though not equal to the others as regards the individual flowers. Plants that are sufficiently large should be cut back to a point a few eyes from that they were pruned to last year, and others should only be allowed to retain well-ripened wood. Repotting may be done at the pruning time, removing half of the old soil, and if the ball be dry soak it in tepid water until thoroughly moistened. Turfy loam, a fifth of well-decayed manure, and a small quantity of sand is a suitable compost. The drainage must be good, and the potting done firmly. Place the plants near the glass and syringe them twice a day. Bougainvillea glabra, which is so well adapted for culture in pots, should also now be cut back and started, or the potting may be deferred until the young shoots are about an inch long. It will also be advisable to start a few plants of Clerodendron Balfourianum, but they must not be reduced at the roots, although the drainage may be rectified and any loose surface soil removed. Plants of the above that it is not desirable to start

for some time must be kept at the coolest end of the house, supplying them with little water, but do not allow the wood to shrivel. Retarding the growth by placing the plants in a low temperature must be avoided, as it frequently causes the loss of the roots. Deciduous and evergreen plants at rest should be fully exposed to light, as it will further assist the ripening of the wood. The temperature must not be increased until the days lengthen, 60° to 65° at night and 70° to 75° by day is sufficient at present. Ixoras and Dipladenias require the warmest part of the house.

## THE BEE KEEPER.

### THE PROGRESS OF BEE-KEEPING.

THE advent of a new year, while our pets are slumbering under the influence of frost and snow, is an appropriate time to review the progress of bee-keeping to the present time and to forecast the probable future of the science in these realms. For the two thousand years during which we have any record of the management of the bee it is probable that no rural pursuit has, until comparatively modern times, made so little progress. Until the close of last century the natural history of the bee was almost a sealed book. The researches of Reaumur and Huber, and more recently of Dzierzon and Berlepseh, first made really improved management possible. Following these came the great modern invention of the moveable comb, with the multiplied facilities it gives for purposes of observation and practical work. By its means, on the basis of real scientific knowledge, the various operations of stocking, depriving, uniting, dividing, contracting, enlarging, borrowing, and helping are now so thoroughly in the power of the bee-master that probably little remains to be desired so far as the hive is concerned. On one point only do I expect an early improvement, and that is in the shape of the comb, and consequently of the hive. Oblong combs of the usual type in bar-frames are undoubtedly a departure from the form naturally selected by the bees, and it remains for bee-keepers to devise a form as nearly approaching the circular as possible, keeping in view mobility and adaptation for supering; and I venture to predict that the many advantages such a form of comb exhibits will so commend it to the attention of bee-keepers that before the year is out we shall have before us a bar-frame hive on quite a new model.

Recent years have been particularly fruitful in inventions and discoveries that enable us in almost every emergency to assist the bees in their work. I need only refer to the improved methods of feeding with syrup, the discovery of substitutes for pollen, the porous quilt or chaff packing, the use of division boards, and the valuable invention of comb foundations. Whether the number of such aids can be increased or not, I venture to say we have yet something to learn in regard to the best methods of employing them. If the fraternity could only be induced to experiment on scientific principles, and publish results properly checked, instead of rushing into print with every new fancy, we should soon be able to form a code of rules bearing on all these operations that would not require alteration.

Equally recent, but not yet so widely diffused, are the two great inventions for depriving—viz., the extractor and the section, the former giving us liquid honey in its purity with comparative ease and rapidity, the latter enabling us to present honeycomb in its most attractive, convenient, and economical form. Here also we are disposed to think we are nearing perfection. The extractor is now a machine that leaves little to be desired, and the latest importations of American-made sections are marvels of ingenuity and workmanship. Only in the matter of separators do I desire improvement. Separators we must have if our sections are to be perfect in finish and fit to glass; but shall they be of tin, or perforated zinc, or wood, or paper? Let us settle this in 1881 by careful experiment.

The market for honey never was more hopeful. Our American friends, after raising a panic and creating a demand by their heavy importations a year ago, have to all intents left the field. So far as comb honey is concerned they have found it a ruinous speculation, and thus the field is clear as regards this our most valuable product. Even in extracted honey they are complaining of their returns; but here we think there is room enough for us both, especially since there is no difficulty in our realising paying prices even in face of their keenest competition. If bee-keepers could only be induced to grade their honey properly, there is no reason why a steady demand should not spring up.

There is honey and honey, from the raw insipid product of the orchard and Plane trees to the rich and piquant Heather, and from the vile aphid secretion called honeydew to the delicious nectar from Clover and Limes. Some of these grades should not be marketed at all; all of them should be labelled as what they are and priced accordingly.

The decade opens hopefully. Never before did the art of bee-keeping enjoy so great patronage. Our rapidly multiplying bee-keepers' societies are to a notable extent enlisting peers and peasants, clericals and laymen, into a common brotherhood. Exhibitions of bees and their produce are now the order of the day, attracting the multitudes as few shows in rural districts have ever done. Men of the highest attainments in science are being anew attracted to the study of the wondrous anatomy and habits of this tiny insect, while its special function in nature as the fertiliser of flowers is being made more and more manifest. It yet remains to see our industry enjoying the direct patronage of the Government as it does in other lands. The honey bee has both an educational and an economic interest that we venture to hope cannot long remain unrecognised in the highest quarters. Let us hope the near future will witness, under Government patronage, the establishment of bee-keeping schoolmasters in every parish, that the poor may learn how to obtain honey to sweeten their bread.—WILLIAM RAITT, *Blairgowrie*.

### CONGRESS OF GERMAN AND AUSTRIAN BEE-KEEPERS.

(Continued from page 606.)

SEPTEMBER 7TH was a day of honour for the meeting of the German and Austrian bee-keepers. At a quarter past ten in the morning Dr. Becker, as chief magistrate and representative of the city of Cologne, opened the meeting in the large Victoria Hall, where more than four hundred bee-keepers and visitors had assembled, among whom were many ladies, the Baroness von Berlepsch, the talented widow of the late Baron von Berlepsch, being prominently one of the number. In a cordial address Dr. Becker expressed the hope that when the fiftieth meeting was held it would no longer be a meeting of German and Austrian bee-keepers only, but an international one of bee-keepers of every nationality. He then introduced Counsellor Wüffling to the meeting as the representative of the Minister of Instruction, and Counsellor Wiesman as the representative of the Minister of Agriculture, Domains, and Forests. Mr. Wüffling, in a speech of considerable length, referred to the importance of bee-keeping as a branch of agriculture, as a proof of which he stated the Government grants valuable prizes and a sum of money in order that these meetings may be held; and, he continued, their excellent Exhibition, which he had viewed with pleasure and surprise, showed that this body of bee-keepers fully deserved the support of the Government. In the name of the Government he thanked them most heartily for their endeavours, and by command of the Emperor he had the honour to hand to their permanent Vice-President, Mr. Andreas Schmid, the decoration of the Order of the Crown. Loud applause continued while Mr. Schmid was being invested with the order conferred upon him. After Dr. Dzierzon had exhorted the meeting to continue in the path of progress, the appointment of fifteen gentlemen as Judges of the Exhibition was proceeded with.

These preliminaries over, the real business of the day commenced; and Mr. Vogel of Lehmannstöl, the faithful joint editor with Mr. Schmid of the *Bienenzeitung*, was called upon to introduce the subject of the normal size of hives. Mr. Vogel began by saying that Mr. Dathe of Eystrup, a well-known and highly esteemed bee-keeper, was to have opened the discussion of this subject, but he unfortunately died suddenly a very short time ago. When hives with moveable combs were first introduced they were generally made 10 Rhenish inches wide, this being the width adopted by Dr. Dzierzon. Some time later this distinguished bee-master made some alteration, reducing the width to 9 inches Rhenish measure. Hives are not, however, made of uniform size in every district. In 1874 this question of uniformity in the width of hives first arose at Halle, and it since had been discussed at various meetings. The Central Association for Saxony, Thuringia, and adjoining districts recommend a width of 23½ centimetres (9¼ inches English) inside, and the same was recommended at the Greifswald meeting. The speaker proposed that the meeting should adopt as a normal 23½ centimetres inside measurement as the width of hives, and 36 centimetres outside measure as the height of frames (18 centimetres the half frame) in order to arrive at uniformity for Austria and Germany. As to the depth of hives, this of course must be left to each bee-keeper to decide for himself.

After much discussion a majority of members finally decided in favour of the proposition of Captain Wächter of Merseberg, who made some observations, which were to the following effect:—"We bee-keepers of Germany and Austria, assembled in Cologne to celebrate the twenty-fifth anniversary of our meeting, desire that for Dzierzon's or Berlepsch hives, no matter whether Lager hives or Standers, as well as for all bee hives the ground plan of which forms a rectangle, the following standard should be adopted—viz., width of hive 23½ centimetres inside measure, 9¼ inches English; height of

half frame 18½ centimetres outside, about 7¼ English." Vice-President Sternberg remarked that the importance of this decision could not be over-estimated, and he was sure it would largely contribute to the advance of rational bee-keeping.

The second subject of the programme of the day was, "How have bee-keepers to proceed after a bad season in order to bring their colonies through the winter without much trouble and expense?"

Dr. Dzierzon, by whom the question was asked, reminded his hearers that in order to answer it satisfactorily every bee-keeper should first ask himself, How ought I really to have acted last year? It was advisable, he said, not to winter any colony which had not collected sufficient food, especially after such a bad season as we had had last year. It was the bee-master's duty to check the increase of his colonies early, and to unite only those colonies which had a reasonable prospect of surviving the winter. He recommended bee-keepers to make their colonies strong in population; to preserve only the most fertile queens; to deprive the colonies of their queen at the right time, in order that the bees may collect more honey; to reduce the number of hives; to unite colonies, and to keep till the following year any old comb which contains pollen. Mr. Lehzen was of a different opinion. He pronounced against the reduction of hives, and recommended the filling of honey casks in good seasons. As you are aware, he said, in seven years we have on an average two good honey harvests; three we may call middling good, two bad. Advantage should be taken of the good seasons to obtain as much honey as possible. According to Pfarrer Deichert it was not only a question of the quantity of honey collected, but also of its quality, of the arrangement of the combs, and the construction of the hive. He did not give the bees any honey which had become granulated, as it was injurious to them in winter. Honey gathered from the Rape blossom had a tendency to crystallise, and should be extracted by means of the slinger. He is of opinion, however, that sugarcandy, which is not expensive, cannot be sufficiently recommended for feeding bees in bad seasons. Pfarrer Deichert also recommends the piercing of the combs to enable the bees to move more easily from one comb to another, and the filling-up of empty spaces in the hives with moss, sawdust, &c., when the cold in winter is severe. Mr. Stursburg wished differences of climate to be taken into consideration, and stated that he had obtained most satisfactory results last winter from feeding his bees on the refuse from sugarcandy, an article still less expensive. Mr. Klausmeyer reduces his colonies to a moderate extent; he uses sugarcandy for feeding when the season is bad, and shuts off the queen from the comb, leaving her only a couple of long frames for breeding. Mr. A. Schlösser agrees with Dr. Dzierzon, and deprecates late and useless feeding. Günther is in favour of shutting off the queen from the entrance to the hive about the middle of June. In such cases he leaves her four to six half frames. Mr. Weygandt strengthens his small colonies by inserting some brood comb. The next question discussed was, "What are the essentials to be observed in order to winter colonies of German, Italian, and Carniolian bees well?" The word "June" in the twenty-sixth line from the bottom of my article on page 606 last week ought to have been printed "jars."—ALFRED NEIGHBOUR.

(To be continued.)

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books** (*H. Martin, St. Honoré*).—If you write to Messrs. Asher & Co., book-sellers, Bedford Street, London, they will send you what you require, except perhaps Stendel's "Nomenclator Botanicus," which we think can only be obtained secondhand. The price of the "Treasury of Botany" (Longmans) is 12s. 6d.; Paxton's "Botanical Dictionary" (Bradbury), 25s.; and Johnson's "Cottage Gardener's Dictionary" (Bell), 6s. 6d. (*W. O. F., Rathkeale*).—We do not know of any works of the kind you appear to desire, and we do not think there are any published.

**Grapes in Peach House** (*Leeds*).—If the Peach trellis does not shade the back wall Black Hamburg Grapes would ripen on the aspect you name. The vines, considering their permanent value, would be best planted out and cropped lightly the first year. If you crop them very heavily the first season they will be of little use afterwards, whether they are retained in pots or planted in the border; but if lightly or moderately cropped they will improve in value yearly. They will succeed in ordinarily fertile garden soil with some wood ashes and a few bones added, and the surface mulched with good manure. They

should be shortened at once to the height required, and when the buds are swelling is a good time for planting.

**Seedling Apple (J. J.).**—The specimens were much bruised and had been kept too long, still there are evidences of merit in your Apple. We should like to see it another year. We will try the Potatoes; some shall be cooked and the others planted. Write to us again in the autumn on the subject.

**Vegetables for Exhibition (A. J. J.).**—The varieties to which you refer are, when well grown, highly suitable for exhibition during the respective seasons when the vegetables are in use. If you require more precise information and state the number of dishes you wish to exhibit, and the month in which the exhibition is held, your letter shall have our attention.

**Mice Destroying Peas (R. H., Bucks.).**—If the peas are moistened with paraffin, and when wet dusted with red lead, the mice will not attack them, and if the seed is sound and matured the dressing will not be injurious. If the rows already sown are covered 2 inches thick with sharp ashes and sprinkled with paraffin the peas will be comparatively safe; the ashes must, however, be spread 2 or 3 inches beyond the rows or the covering will not be effectual. You should trap the depredators. Many may be caught with figure-of-4-traps, and we know a gardener who last year caught scores of mice by sinking 10-inch pots so that their rims were level with the soil, the pots being half filled with water in which some bread was placed; the mice went freely into the pots and were drowned.

**Disbudding Vines (Reader.).**—Permit the growths to extend until you can see the bunches, then rub out the barren shoots unless they are very numerous, permitting the others to grow and set the fruit. When you have a sufficient number of bunches that promise to swell freely remove the others. You might indeed remove them before if you could insure a "good set," but owing to unfavourable weather and other causes the fruit on Vines in pots does not always set so freely as gardeners wish, and a few extra bunches do not exhaust the Vines provided the superfluous bunches are cut immediately the others are set, and before the berries are large enough for thinning.

**Pruning Figs (Idem.).**—The Fig tree shoots must be shortened for securing bushy heads, and the young shoots following may be topped when they are 6 inches long, so that a second growth may be made, which with good attention will form embryo fruits. You will find notes on Fig-pruning in another column.

**Ledsham's White Broccoli (Inquirer.).**—The name "Ledshaw," as it appears in the "Gardeners' Year Book," is, as you suggest, a "printer's error." The Broccoli referred to was raised by Mr. Samuel Ledsham, of Green Lane, Tarvin Road, Chester, and is named Ledsham's White. It is a variety of considerable merit, or it would not have been commended by the Fruit Committee of the Horticultural Society. It is to be tried at Chiswick, and is not yet in commerce.

**Removing a Peach Tree (Barker.).**—You may safely remove your five-year-old tree now, due care being exercised in the performance of the work. At a distance from the stem equal to the length of the branches, take out a trench 2 feet wide, and below the roots; into this trench carefully fork the soil from the roots, throwing it back as the work proceeds, and continue the process until the tree can be lifted from its place with its roots intact. Before, however, this is done have the station ready where the tree is to be planted. We have known men so thoughtless as to dig up a tree and carry it about "seeking a place" for it. By the time this was found the roots were so dry as to necessitate hurried planting, which means slovenly work and its attendant evils. Remove any injured roots, plant carefully, and do not force the tree the first season in endeavouring to have the crop ripe before July.

**Inarching a Vine (A. Novice.).**—As we understand your letter, the very strong Vine to which you allude is a Muscat of Alexandria, although you do not say so. The Vine named forms one of the best of stocks, and it being in vigorous health we should certainly prefer inarching it with another variety to removing it and planting a young Vine. If you have a Vine in a pot the work will be easy; if you have not, we should "bottle graft" the Vine, which is similar to inarching, the scion being sufficiently long so that 6 inches of its lower portion can be inserted in a wine bottle kept filled with water. The water will support the scion until its union with the stock is complete, and the growth will probably be as strong and free as would follow from a young inarched Vine with roots to support it. Your other question is fully answered on another page.

**Uncovering Vine Borders (T. G. G.).**—There is little doubt that your Vines sustained injury by the heavy covering of hailstones immediately after the manure was removed from the border, the Grapes at the same time having commenced colouring. When fermenting material has been on a Vine border for some months its removal must be effected with great care, and should not be done until the weather is warm and settled. It is often injudicious to remove the whole of the covering, as the roots may have penetrated it, and if not they are, or ought to be, quite close to the surface, and consequently especially liable to be injured by hail or drought. A layer of the manure surfaced with turfy loam, wood ashes, and bones would afford not only protection to the roots but sustenance of great value for the Vines. We have known instances when the injudicious removal of the covering material has resulted in Vines being in a worse condition than they would have been if the borders had not been covered at all. Placing fermenting material on Vine borders is often very advantageous, but it must not be placed on too soon, nor be removed too soon, as there is assuredly danger in both these extremes.

**Pear Tree Branches Dying (E. S.).**—In consequence of the extremely wet and cold season of 1879 the growths of many fruit trees were not matured, and the severe frost following had a most injurious effect on them. Even in the south of England the young growths of many Apple and Pear trees were quite killed last winter and others seriously injured. Your trees may have suffered from the same cause, and the wood sent also indicates that the roots of the trees have penetrated wet and unsuitable soil. As they are young we should lift them, removing all the most unhealthy and injured portions of the roots with a sharp knife; drain the land, prepare fresh stations, and replant in fresh loam and charred refuse, no manure to be mixed with the soil, but a good covering placed on the surface. All the dead and unhealthy wood must be cut from the trees, and with fresh root-action in good soil healthy growths may be expected to follow.

**The "Candle Cactus" (G. M. H.).**—The plant of which you send a specimen under the above name is *Cacalia articulata*, which has no affinity to a Cactus, being included in the natural order Compositae, but it probably owes the popular name you give to its peculiar fleshy stems. It is a native of the Cape of Good Hope, whence it was sent to this country more than a hundred years ago, and is now well known. It bears yellow flowers in late summer or autumn, and requires to be grown in a greenhouse near the glass. A light porous soil is needed, and moderate supplies of water in hot weather, but very

little at this time of year. Possibly you have the plant in too much heat, though the specimen sent appears quite healthy. The book you require is no doubt the "Cottage Gardeners' Dictionary," of which a new edition will be published in the spring of the present year. The price will be duly advertised.

**Keeping Pears (Idem.).**—A temperature of 40° will be suitable for keeping the Pears, but the fruit will be of much better flavour if ripened in a warmer place. If you place a few fruits at a time in a temperature of 60° to 80° they will not only be much improved in quality by the additional heat, but any given variety may be had much longer in use than if all the fruits were left in a cool place to ripen together.

**Peas for Succession (G. S.).**—The following are good and inexpensive, and vary in height from 3 to 6 feet:—Early—William I. and Essex Rival; second and general crops—Champion of England, G. F. Wilson, Dr. Maclean, Huntingdonian, Princess Royal, Laxton's Fillbasket, and Maclean's Wonderful; late crops—Veitch's Perfection, British Queen, Omega, and Ne Plus Ultra. We have named twelve varieties because you have desired us to do so, but if your only object is to ensure a succession of Peas of excellent quality half the number of varieties would be ample. We should prefer disentangling some of the growths of the Lapageria and tying them down instead of cutting down a portion of the plant.

**Papers and Plants "Boycotted" (S. T.).**—The publisher will attend to the question respecting the non-delivery of your paper. We are not "Boycotted," for the post office and newsvenders appear glad to take all the papers we can send, and we send all that are ordered. The *Selaginellas* we received from you were totally unrecognisable, as they were so small, crushed, and withered. The second box to which you refer we have no recollection of having received. If you send good specimens that arrive in fresh condition we will endeavour to name them.

**Names of Plants (A. Novice.).**—All the specimens were very much shrivelled, but 1 resembles a small leaf of *Grevillea robusta*; 2, *Alonsoa Warscewiczii*; 3, *Eupatorium riparium*. (W. J. M.).—*Sollya linearis*, a native of Australia, and figured in the *Journal of Horticulture*, vol. xxxvii, page 212.

#### COVENT GARDEN MARKET.—JANUARY 5.

BUSINESS remains very quiet, the only alteration being in Grapes, which are now in good demand and making full prices.

#### POULTRY AND PIGEON CHRONICLE.

##### A RETROSPECT OF THE HOME FARM, 1880.

WE have once more arrived at the period when we feel it desirable to review the circumstances by which the home farmer has been surrounded during the past year, many of them having proved most perplexing and disappointing as regards the practical operations of the farm. To the best of our judgment and experience we have during the past year continued to furnish in this Journal our weekly contributions under various headings, as well as the remarks referring to the work of the farm, which we felt to be necessary as the seasons advanced, when the work of the period may with advantage be anticipated and provided for. As in former years we have been particular in enumerating the practical operations of the farm, and although to experienced men

the details might have appeared unnecessary, yet our principal object is to inform the novice and the beginner in agriculture.

Our retrospect will commence with the month of October, 1879, this being practically the first month in the agricultural year, as it is the period for sowing Wheat, the chief sale crop or rent-paying produce of the arable land. It is remarkable that one of the lightest rainfalls on record was that in the three months of October, November, and December in 1879. This enabled the farmers in nearly every district, but especially in the midland and northern counties, to complete Wheat-sowing under very favourable conditions as to the weather. Unfortunately, however, much of the seed corn of that harvest was ill-matured, and the Wheat plant in consequence did not flourish in the winter; the frost, too, at times being severe much of the plant perished, or later in the spring was eaten by slugs. A very deficient plant of Wheat was the result in most districts, but as the spring wore on—the weather being dry in March, April, and May—the plants tillered and appeared very promising. Still the results were not satisfactory, although where a good plant was saved through the winter the Wheat yielded fairly in most instances, yet in those numerous cases where the plants were too thin they were so weakened by the tillering process and hasty growth that they fell a prey to blight and mildew during the heavy storms and floods which occurred in July, twenty-six rainy days being recorded during that month. With respect to the seed time for pulse crops as well as Lent corn, owing to the months of January to May inclusive being favourable, all these crops were sown in good time with the soil in fair condition throughout the kingdom. These crops promised well—especially Beans, Peas, and Oats—until July, when the dreneching and flooding rains rendered the crops so broken that they suffered in every district, especially the Barley, which in most instances was beaten to the ground.

The harvest for cereals and pulse crops commenced in 1880 during the first week in August, and with the exception of two heavy storms on the 7th and 25th days of this month the weather was generally favourable down to the 11th of September, thus giving time for securing the crops in the early districts throughout the southern and eastern counties in fair condition. From this date a general change of the weather occurred, and during the four or five following days  $3\frac{1}{2}$  inches of rain fell, which greatly impeded harvest operations in the late districts, and until the close of the northern counties harvest immense damage was sustained by all the cereal and pulse crops. Now, this was just the reverse of the operations during the previous year, for being late the northern counties enjoyed a favourable harvest, whilst in the southern and forward districts immense damage was done to all the cereal produce, a very large portion being unsaleable, and was used for feeding cattle and pigs. Referring to the crops of corn and pulse arising from the harvest of 1880 we give the following particulars, gathered from the various published reports of experienced men residing in different districts throughout the kingdom. Wheat is considerably under a good average. Barley, Oats, Beans, and Peas are, upon the whole, above an average. We must add, however, that the samples of Wheat are far better in quality than in 1879. The samples of Barley are not of so good malting Barley as was expected, and a large portion was seriously stained by heavy rains in the midland and northern counties. The crops of hay and also of green fodder were very deficient in most instances, and the early crops of hay as near totally spoiled as we ever remember having seen them. The second crops of Clover, however, owing to the continuous rains in July, proved of great bulk, and the dry weather during the harvest month enabled the crop to be stacked in good condition; we have therefore an average crop of hay for use, although for the most part both field and pasture produce of inferior quality. Root crops have greatly flourished, for although the Mangold seed did not generally vegetate with regularity, yet the few acres seeded early proved a magnificent produce, and the aftergrowths of the remainder being luxuriant an average crop has been the result. Of Swedes and Turnips, Cabbage, and Carrots there has never within our remembrance been a finer crop of rare feeding quality; therefore with an average crop of hay, although damaged, and an abundant root crop, the animals of the farm may fare well during the coming winter without any unusual outlay for artificial foods. The Potato crop, fast becoming an important produce to the home farmer, has this year upon the whole proved an almost unparalleled and healthy produce; but in various districts where the flooding rains fell with the greatest severity much of the crop has been lost by the disease. If, however, we take the aggregate produce we shall find that the Potato crop, as a whole, is one of the best quantity and quality considered that has been secured for some years.

The live stock of the kingdom, at all times both important and

interesting, has this year called forth unusual attention from the agricultural classes, consequent upon the enormous losses of 1879 by the eoathe and rot. Unfortunately the mischief has not ended with that year, but, in consequence of the storms and floods of July and the succeeding autumn months, much of the grazing and park lands of the kingdom have been seriously injured by floods. This has been the case more especially in some of the midland counties, and has again brought the entoza of the fluke into life and activity, and the flocks of sheep which depend principally upon grass feeding are again seriously affected by the fluke rot. Unfortunately this has in some instances been the cause of ruin to the farmers. We have, however, occasionally advised them upon the best way of avoiding this, by not feeding grass down too bare where the sheep have previously been coathed, also to allow them a good mixture of food the produce of the arable land, with a liberal allowance of cake and bean meal, and by all means to allow them access to salt, and have high and dry night quarters. At the same time we advise that such grazing lands should have a heavy dressing of salt twice a year, the quantity to be ascertained by experiment in order that it may not destroy vegetation. We hold to this matter tenaciously, because in our salt marshes where the sheep feed once a day we have never had a diseased sheep during the whole of our agricultural experience, although the sheep may have fed at some period upon meadows of very doubtful character upon the chalkhill and stonebrash farms. The sheep, although short of keep in the spring months, have proved more healthy than for some years past, and especially free from foot rot and foot lameness; in fact the fall of lambs has been a good average, and the general health of the breeding flocks on the hill farms has been good, they have also sold at a good price in consequence of the serious losses on the low lands and vale farms. We have only occasionally had to report pleuro-pneumonia amongst cattle, and typhoid fever in swine during the spring and summer—in fact, the health of cow stock has been good for several years, but during the past three months we have again to report serious outbreaks of foot-and-mouth disease in the horned cattle, sheep, and swine also, in several of the southern and south-eastern counties, and likewise in other and various districts, and the prospect at present is bad, because in spite of all precautions of the authorities the area of the disease seems to extend. No doubt the disease has been imported from abroad, in proof of which the country was entirely free from it for the past two years. It looks, therefore, that we shall have to make a new departure, so that all our cattle should be slaughtered at the port of disembarkation, except store cattle, which should be subject to careful and lengthened quarantine, because our present system of surveillance has proved ineffectual. For we have reason to believe there are districts where imported store cattle passed by the inspectors and sold as sound stock at the local fairs, have broken down with disease soon after arriving at their winter quarters. The seed time for Wheat has been very prolonged this autumn in consequence of fine weather only prevailing for short periods; it has, however, at last been concluded, and the young Wheat plant looks generally as strong and healthy as we have ever seen it. Let us, therefore, hope that our crops another year may prove more favourable than for several years past, and thus to some extent remove agricultural depression.

[In the fourteenth line from the bottom of the first column, page 602, last week, the word "deprivation" should have been printed "depreciation."]

#### RETENTION OF SOLUBLE MATTERS BY SOILS.

ONE of the many wonderful powers which the soil possesses is that of absorbing out of their solution in water certain substances, such as, for example, phosphate of lime and salts of ammonia. Our earliest information in reference to this absorptive power of soils was derived from the results of some experiments made in 1844 by Messrs. Thompson and Spence. They filtered solutions of salts of ammonia through layers of soil, and found that the ammonia was retained by the soil. In the Journal of the Royal Agricultural Society of England for the years 1850, 1852, and 1855 Mr. Way published the results of numerous experiments on the property of soils to retain certain ingredients of manure when subjected to the action of water. A certain quantity of the substance to be experimented with was dissolved in water, and the solution passed through a layer of soil of 10 inches or more in depth. The water which passed through was analysed, and in many cases it was found to have lost all or portion of the solid matters which it had contained.

Amongst the interesting results obtained by Way may be mentioned that soluble or superphosphate of lime was wholly removed from solution by the soil, and the superphosphate was not subsequently washed out by repeated applications of water to the soil.

The phosphate and carbonate of ammonia were wholly removed from solution; whilst in the case of the nitrates, and sulphates, and chlorides of ammonia, potassium, and sodium only the bases (ammonia, &c.) were retained, whilst the acids passed through.

Some bases are taken out of solution to a greater extent than others. According to Kullenberg, the salts and alkalies are retained according to the following order, the most readily absorbed being first—ammonia, potash, magnesia, lime, and soda. The last named base passes very readily out of the soil; and as nitric acid is also not easily retained by the soil, the nitrate of soda is liable to be carried out of the ground by drainage water.

The study of the composition of drainage waters throws light upon the absorptive properties of soils. The analysis of the latter shows that it contains the phosphates in large quantity, often from 0.5 to 1½ per cent. of potash salts, and small, but about equal, quantities of ammonia and nitric acid and of soda salts.

In the drainage waters the nitrates greatly exceed in quantity the ammonia compounds, and they contain much common salt. From one to twenty grains of nitric acid per gallon are often found in them; whilst it is rarely that in these waters so much as the twentieth part of a grain of ammonia is found. As for the phosphates, only the most minute trace is found in drainage waters, and often not even a trace.

As salts of ammonia and superphosphate of lime are retained with so much tenacity by the soil, these substances may safely be applied long before they are required for the use of plants. Farm-yard manure may be spread out upon the field in winter, and exposed to rain with perfect impunity; for the ammonia and phosphoric acid compounds which are carried down into the earth by the rain will be kept securely by the former until required by the plant. On the other hand, nitrate of soda should be applied only at the time it is actually required, or shortly before that time; for, as we have seen, this article is retained by the soil only to a very trifling extent.

It has been found that the very stiffest clays are not the worst absorbents of manurial ingredients. Sandy soils are not bad absorbents; but they are inferior to the light loams. The absorbent powers of the stiff soils are greatly improved by cultivation, by every process which renders them more porous. Just in proportion to the degree of porosity brought about by tillage will also be the beneficial effect produced upon the inert vegetable matter within the recesses of the soil by the action of the air freely admitted from without.—(*Irish Farmers' Gazette*.)

#### VARIETIES.

THE firm of agricultural engineers of Messrs. Ransomes, Sims, and Head of the Orwell Works, Ipswich, and 9, Gracechurch Street, London, will in future be designated Messrs. Ransomes, Head, and Jeffries, Mr. Sims' term of partnership having expired.

— SALICYLIC ACID *v.* FOOT-AND-MOUTH DISEASE.—The following letter has been published by E. H. Moore, County Analyst, Brighton:—"The valuable antiseptic properties of salicylic acid render it of infinite use as a local application in foot-and-mouth disease. Being perfectly harmless, it is equal to most of the remedies used without any risk. Its solubility is arrived at in a convenient form as annexed:—Salicylic acid, 60 grains; water, 1 oz.; glycerine, 2 ozs. Dissolve in a glass beaker at a gentle heat."

— LATE ENTRIES AT POULTRY SHOWS.—Complaints are frequent of secretaries receiving entries after the advertised date. A certain amount of unfairness cannot fail to result from the practice, as it gives the old hand who knows that his entries will be received a week or so after date an advantage over the beginner, who believes that the announced date is adhered to. Seldom, however, has the system been carried so far as at the recent Ryde Show; there entries were accepted so late that the catalogue was actually in print before they were received, and the numbers of many of the winning pens given in the prize list were not to be found in the catalogue. Moreover, the Secretary, who was the most to blame in the matter, actually wrote to our representative to ask him to draw the attention of exhibitors to the inconvenience he suffered from the late entries!

— SALE OF HOMERS.—We much regret to note the breaking-up of the stud of Belgian Homers, the property of Mr. John Hudson (of Pelican House, Peckham Road, London), which are advertised in our columns as for sale by Mr. Stevens, at his rooms, King Street, Covent Garden, on Tuesday next, 11th inst. Mr. Hudson has been so well known for the last forty years as an importer and breeder of

Homers—many of our best known birds, both for long distances and for taking prizes in the show-pen coming from his lofts—that we are sorry to hear of his retirement from the fancy.

— WHEAT-MEAL BREAD.—The Bread Reform League has had a conference at the Mansion House under the presidency of the Lord Mayor, and is supported by a distinguished and influential list of patrons. The object of the organisation is solely to impart information on the great advantages of Wheat-meal bread as made on Dr. Campbell Morfit's process of preparing the meal in a quasi-granular form instead of flattening it with the ordinary millstones, by which the flinty and irritative parts of the husk are retained. No one connected with milling or baking can become a member of the League, and there are no paid officials on the staff, all the funds that are subscribed being expended for the public benefit in advancing a system of bread reform. The League is anxious to forward at once to every clergyman, doctor, and chief magistrate in the kingdom an account of the Conference, and a copy of Miss Yates' lecture (which contains all instructions necessary for grinding the Wheat and home baking), so that those who visit amongst the poor, and those who in any way can influence public opinion, may be induced to promote a movement so highly conducive and devoted to the general welfare of both rich and poor. The Honorary Secretary of the League is Miss Yates (Ladies' Sanitary Association), 17, St. Edmund's Terrace, Regent's Park, London, N.W. We have tried this new bread and found it excellent, and superior to the ordinary brown bread now in use. We have also read Miss Yates' lecture, which contains information of practical importance.

— BANTAM CLUB.—We see that efforts are again being made to form a Bantam Club. While we think the Poultry Club is the proper centre for all fanciers, we must admit that the Bantam exhibitors have recently had much to complain of, and perhaps have special need for a club of their own. At Birmingham a pair of Pile Game Bantams were awarded first in the class for "Any Other Variety of Bantams, cock and hen," there being separate classes for Game Bantam cocks and Game Bantam hens, in which the Piles might have competed, and in which, in fact, most of the prizes went to Piles. Again, at Leeds there was a class for Game Bantam cocks, any variety; then classes for Reds, Duckwings, Blacks, Whites, Sebrights, and Any other variety. Here again Piles monopolised all the prizes. This case was perhaps more doubtful than the other, as, although there was a class in which Pile cocks might have competed, and did compete, there was no class open to Pile hens. We think schedules should be drawn up with more care to avoid questions of this sort arising, and we commend the matter to the attention of those about to form the Bantam Club.

— THE EXTINCTION OF PLEURO-PNEUMONIA.—In the "Veterinary Journal" for December, which is edited by Mr. Fleming, the following remarks appear:—"The measures applied by the Dutch Government for the extinction of lung plague have been crowned with the utmost success. The decrease in the number of cases has been rapid since the adoption of these measures, and from September 4th until October 2nd, the date of last information, no cases had been reported. Holland had been recognised as free from contagious bovine maladies by the German Government, and restrictions have been accordingly removed. It may be remembered that the measures adopted in Holland were voluntary inoculation where lung plague was not in existence; but on infected farms slaughter of cattle really diseased, and compulsory inoculation of those not showing signs of the malady, had to be carried out. The value of inoculation, as on other occasions, has been most clearly demonstrated, and has proved to be as certain a protective as vaccination is of human small pox. The mortality following inoculation has been small, and no instance has been adduced of the disease having been spread or perpetuated by the operation. The experience of Holland dispels many notions entertained with regard to inoculation, and we can only regret that unfounded prejudice and narrow-mindedness have prevented this most valuable prophylactic from saving the country many thousands of pounds."

— CAMBRIDGESHIRE ORNITHOLOGICAL SOCIETY.—The third Exhibition of poultry, Pigeons, cage birds, and rabbits, open to the

United Kingdom, will be held in the New Corn Exchange, Cambridge, on Tuesday, Wednesday, and Thursday, February 1st, 2nd, and 3rd, 1881, under distinguished patronage. The following special prizes are enumerated in the poultry classes:—1, Piece of plate or cup, value £5, will be given by the borough Members, W. Fowler and H. Shield, Esqs., M.P., in lieu of the first prize, for the best pen of Brahmas exhibited in Classes 3 to 6 inclusive. 2, Piece of plate or cup, value £5, will be given by L. C. C. R. Norris, Esq., in lieu of the first prize, for the best pen of Cochins exhibited in Classes 7 to 10 inclusive. 3, Piece of plate or cup, value £5, will be given by a few fanciers in lieu of the first prize for the best pen of Dorkings or French exhibited in Classes 11 to 14 inclusive. 4, Piece of plate or cup, value £5, will be given by the Rev. E. H. Morgan, in lieu of the first prize, for the best pen of Game or Game Bantams exhibited in Classes 15 to 20 inclusive. 5, Piece of plate or cup, value £5, will be given in lieu of the first prize, for the best pen of Hamburgs exhibited in Classes 21 to 25 inclusive. 6, Piece of plate or cup, value two guineas, will be given by Charles Reed, Esq., in lieu of first prize, for the best pen exhibited in Classes 26 to 29 inclusive. Special prizes, amounting to one guinea and a half will be given by G. C. Livett, Esq., for best four pens exhibited in Class 30. Specimens of poultry which have won a prize or prizes in open classes at the Crystal Palace or Birmingham Shows in 1880 will not be eligible for competition at this Exhibition. Special prizes are also offered for Pigeons and cage birds. All certificates of entry accompanied by cheque or post office order must be sent in or posted to the Secretary on or before Monday, January 10th. Late entries, if sent in or posted on or before the 15th of January, will be accepted only on payment of the ordinary entrance fee, and half that amount in addition for each entry. The whole of the specimens must be delivered carriage free at the New Corn Exchange, and placed in the pens or on the stages on Monday, January the 31st, or they will be too late for competition; if the carriage cannot be paid through, notice must be previously sent to the Secretary, otherwise the specimens cannot be received. Unhealthy specimens will not be exhibited, but immediately returned to the owners, and the entry fees forfeited.

## POULTRY AND PIGEONS

### POULTRY IN 1880.

THE year 1880 has been a favourable one for poultry. The spring was dry and not severe; and during the summer months, when excessive drought often retards the growth of chickens, abundant rains gave them a plentiful supply of insect food. Then came the lovely harvest time, which brought early birds into good feather and condition. A sight of one or two September shows at once led us to think that the year was not behind in early maturity of its birds, and the aspect of the great shows quite bore out this first impression. Many young birds of various breeds have been seen which at eight months old might well compete with adults, and which promise after another moult to grow into magnificent cocks and hens. In one or two instances so remarkable has been their size and development as to lead to controversies, or at least disagreeable insinuations as to their age. Objectors on this score should at least have some strong presumption, if not proof, of their point before entering protests against awards. In one notorious case not only was there nothing but the vaguest suspicion to support a protestor's plea, but abundant proof from independent witnesses was fortunately forthcoming as to the youth of an undoubtedly, in appearance, matronly pullet. The fact is that really careful and judicious feeding where birds are kept in small numbers can produce a size and early maturity which is quite surprising. On the whole we have not observed any great advance or decline in any of the most prominent breeds during the year. Dorkings are again, we rejoice to see, shown of the true Dorking form, and not the tall Malay-like creatures which bore off laurels some three or four years ago. This improvement has, we believe, come about from some of the most successful breeders of the variety temperately urging on the judges a return to the squarer type of bird, and from their continuing to show such in spite of much disappointment during two or three seasons. It has in part too, perhaps, been aided by some of the special admirers of Dorkings having frequently become their judges.

Competition in Light Brahmas becomes more and more severe, and the variety has been bred up to a point which would surprise the fanciers of a few years ago; the Darks are more stationary, but the one point which of late seemed lacking to the breed is, we are glad to see, now being regarded—viz., the combination of the fine size and robust form which the breed once had with the beautiful pencilling which has been produced within the last five or six years. In both varieties we regret to see the excess of vulture hocks which is now allowed. We always deprecated the making of hocks a necessary disqualification; but this is one thing, their requirement another. Such a change, too, from the standard of a few years ago is puzzling and discouraging to novices.

Cochins hold their own; in their case we regret even more than in the Brahma classes to see sweeping hocks in the prize pen. The Cochin is a bird of fluff and rotundity, and to our taste a stiff hock is as out of place on its legs as are sweeping sickles in its tail. Rumour says that there is to be a fresh attempt to obtain a new standard of excellence drawn up; if so, we hope that some understanding will be arrived at as to the most desired shades of colour for Buff Cochins, and the proper type of pencilling for Partridge, or rather we hope that choice in both will be left to the taste of breeders. At present some judges seem to have special narrow predilections to so exclude at times otherwise magnificent birds from the prize list because their particular tint is not the approved one. We have been specially struck here and there with Partridge hens considered of too grousy a shade which have been neglected.

Game are still perhaps more carefully bred to pedigree than any other breed, and, what is more, the great Game breeders seem well agreed among themselves as to all points desired, and generally unite in praising or condemning awards. Witness their unanimity of satisfaction at Mr. Lyon's wonderful double triumph at Birmingham. Polish and Spanish continue excellent in the hands chiefly of their old admirers. It is a pity that more practical breeders do not discover the fact that the former is not a delicate breed, and that for a table cross it is a most useful fowl. Hamburgs would be far more generally popular as exhibition birds if once for all trimming of combs could by general consent be abandoned. It is but a month since we heard a most enthusiastic admirer and successful exhibitor of the Black variety discussing whether he could keep it any longer on account of the way in which their combs are almost universally tampered with. Leghorns improve in size. We have lately seen the opinion of a clever fancier in point, that the yellow earlobe in this variety, to remove which much pains has been taken, is appropriate to the breed; here is another point of discussion for future revisers of the standard of excellence. Plymouth Rocks seem emerging from the variety class; we know not in what points they surpass the older Cuckoo breeds.

We have not in 1880 observed any striking additions to the said class, save birds which bore unmistakeable signs of mongrel origin, and which would therefore have been better placed in collections of cross-bred fowls. Bantams are promised a club! They need it, and we trust it may succeed. Japanese are the reigning favourites, and mustered strongly at the Crystal Palace. If the classification of Bantams were improved many almost extinct varieties might be resuscitated. Pekin Ducks continue their advance in popularity, and bid fair soon to be spread almost generally over the kingdom. We know of several cases in which kind and patriotic fanciers have given them to cottagers, who are finding them most profitable inmates of their little gardens.

That the year 1881 may not be behind that which is past we sincerely trust, and wish our readers much pleasure and profit from their poultry yards.—C.

### GRASS IN POULTRY RUNS.

It is generally understood that the best run for fowls is that composed of good grass. Experienced poultry-keepers always provide it when it can possibly be obtained, and beginners think, as a rule, that fowls will not do well until a grass run is secured. This is correct to a certain extent. A good grass run never fails to be an advantage, but it should not be forgotten that fairly good results have been had without it. In such cases I am inclined to attribute success to the care that is taken in other ways, and the provision made in finding a constant supply of green food to compensate for a deficiency of grass. Indeed I am of opinion, when this is done with due attention it is of much more benefit to the fowls than a bad grass run. When a large number of fowls are confined on a small run the best of skill and the greatest attention to cleanliness often fail to prevent it becoming half dead, and then it is worse than no grass, as it cannot be so readily cleaned as a sand, gravel, or earth run. But grass runs bear a great deal of

wear and tear provided they are well made at first. The smaller the space the more reasons there are that it should be well made, close in the grass, and firm in the bottom.

In making new runs turf can sometimes be had to lay down at once, but unless it is good it would be much better to begin with seed. Last April I tried both modes, and I decidedly prefer the seed, as it produced a dense mass of clean grass in a surprisingly short time.

Previously to sowing the seed it is well to have as great a depth of soil on the ground as possible. From 4 inches to 1 foot will do if no more can be had. The shallower it is the richer it should be made, and at all depths manure is beneficial. It should not be placed as a layer on the surface, but be mixed with the surface soil. This can be done on a dry day, and when the soil is in suitable condition the seed should be sown. Moderately thick sowing will produce the best turf, and the seed should be raked into the soil and rolled afterwards. The last operation may be repeated every two or three days until the grass is ready for cutting, and during this time the fowls should not be allowed to be on it. After the grass is high enough it must be cut frequently, which improves a lawn quickly in the bottom. In runs where the surface has become uneven the holes should be filled about the end of March and fresh seed sown. This will give a fine lawn for the young chickens when turned out in May and June.

When turves are placed down they should be beaten very firmly at the time, and rich soil underneath causes them to make more luxuriant growth than they otherwise might do.—J. MUIR.

#### PRACTICAL SCIENTIFIC POULTRY BREEDING.

THERE is hardly any subject upon which opinions more widely differ than upon the best method to be pursued in the breeding of exhibition stock. This diversity of opinion is perhaps to be accounted for by the fact that well-known breeders have succeeded in producing the uniformity of excellence aimed at by apparently widely different methods. We say "apparently" different advisedly, and we trust that before we have concluded the subject our readers will agree with us that the difference is more apparent than real.

To in-breed or not to in-breed is the question which first presents itself, and when that has been decided there follow other questions of almost equal importance. We propose in this and following papers to discuss scientific breeding as applied to poultry and Pigeons. The theory of breeding is similar to that observed by the breeders of larger stock, but in consequence of the difference of conditions existing as to length of life and similar matters the practice is of necessity dissimilar.

We do not intend to go very deeply into the scientific question, but rather to deal with the matter practically. It is necessary, however, that we should, for the benefit of less experienced readers, begin by defining a few of the leading terms. In the first place, then, what is in-breeding? It consists (for our purpose) in the mating of birds which are related in blood to each other. The relationship may be the near, as that of brother and sister, or remote, a mere fortieth cousinship for instance; but if there be any relationship between the birds which are mated it is in-breeding. "Prepotency" is another term which must be defined. It is the power possessed by a bird of stamping his or her likeness upon the progeny of a union to the exclusion of the likeness of the other parent. "Heredity" is the inheritance by offspring of the characteristics or likeness of their ancestors more or less remote. A "strain" is, properly speaking, a family with established and recognised points of mutual resemblance. A "breed" is generally understood to mean a natural division of species differing in certain distinct points from all other species. A breed may consist of several "varieties," agreeing in certain common features but differing in others. Varieties are generally artificially produced, or they may be produced by different climatic or similar influences operating upon certain individuals of a breed. They may also be the result of a "sport," which is an accident or freak of Nature, whereby is produced offspring differing in some important point or points from the breed or variety to which its parent belonged. "Throwing back" is a return by the offspring to the original or natural type of the parents.

The theory of "natural selection" and of "the survival of the fittest," to which we shall have occasion to refer, put shortly is as follows:—Birds, as other animals, in a state of nature select their mates partly on account of their superior strength, &c., and partly on account of certain beauties pleasing to the eye. In addition to this the weaklings of each brood die, and those the plumage of which is least adapted for concealment from predatory animals, &c., fall a prey to their natural enemies. In both these ways the

strength of the stock is kept up, and a particular type of plumage (that most pleasing to the eye of the other sex or that most suited for concealment from enemies) is perpetuated. "Artificial selection" is entirely different, and consists in the first instance in the arbitrary settling by man of certain features which he desires to perpetuate, and the perpetuation by artificial means of these features.

Having said so much by way of explanation we come to the first great question, Is in-breeding desirable? Much has been written on both sides of this question, and many statistics have been prepared by the advocates of each view. Into these we shall not go, but the concise result of the whole matter seems to us to be this: In-breeding is not of itself injurious. In theory you might in-breed for ever and do no harm, subject only to the proviso that the original pair chosen for the experiment were entirely free from any disease or latent tendency to disease. In practice this proviso is so difficult to fulfil that success in extreme in-breeding is the exception and not the rule. The importance in practice of this consideration of perfect health may be demonstrated thus: We take two birds, A and B, both apparently in perfect health. A is the bird of the exact type which we desire to perpetuate, and from whom we mean to in-breed. A has a latent tendency to, say, liver disease. B has no such tendency. From the offspring of the union of A and B we select the bird most suited to our purpose and mate it with A. This bird is half A and half B. The progeny of this latter union are three-quarters A one-quarter B. One of these again is chosen and mated with A. The produce are seven-eighths A and only one-eighth B. We have thus a number of birds partaking very strongly of all the tendencies of A, and having these intensified by the fact that they have only one-eighth of any other blood to counteract these tendencies. The tendency to liver disease has probably been developed by this into actual disease, and this is caused by the in-breeding. Had there been no in-breeding the young birds would only have had in them one-eighth of the blood of A and seven-eighths of various other letters of the alphabet, none of which probably had a tendency to liver disease. If both the original pair, A and B, happen to have tendencies towards the same disease the evil result will be arrived at all the more rapidly. It will be apparent, then, to our readers that however harmless in-breeding may be in theory, in practice the probability of evil resulting is most material. In future notes we shall endeavour to show that, notwithstanding this risk, the fancier can only hope for success by judicious in-breeding.

OUR apiarian department is with this number placed in connection with gardening, as more appropriate than associating it with the home farm and poultry sections of this Journal, and this arrangement will be continued in future under the heading of THE BEE-KEEPER.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

26th.—Overcast and cold, sunshine for a short time at noon; misty towards evening.  
 27th.—Snow during night, which rapidly disappeared; mild and rainy all day.  
 28th.—Wet morning, clearing by noon; damp and mild throughout.  
 29th.—Mild and overcast with rain nearly all day; very heavy rain in evening and high wind; colder at night; at 11 P.M. fine and starlight.  
 30th.—Slight fog in morning, and ground white with snow from 7 till 9 A.M.; fair but cold rest of the day, with a glimpse of sunshine at 2 P.M.  
 31st.—Morning fine, clear, and cold; snow in forenoon; bright sunshine from 1 P.M. till 3 P.M., giving a good opportunity for seeing the solar eclipse.  
 January 1, 1881.—Cold, calm, and damp day; dull and overcast in evening, but milder.

\* A week of average temperature, but more than average rainfall. The total fall in the past year was 30.28 inches, which is about 5 inches above the average here.—G. J. SYMONS.

### GALVANISED WIRE AND FRUIT TREES.

(Concluded from page 2.)

**P**UBLISHED evidence on this subject has shown that the injury to trees is by far the most pronounced where smoke prevails; and if the cause of that injury is due to the escape of acid from the wire then it seems to follow, as was stated last week, that all the worst wire—that containing the most acid—has happened to be sent to the vicinity of towns, and the best—that containing the least acid, to the country districts where the air is pure and the trees not nearly so seriously nor generally affected. It is not possible that such a division of injurious and safe wire could have occurred by chance; and the different effects of the wire, assuming that the escaping acid is the sole cause of the injury, can only be accounted for in one way—namely, that the wire has a much slower sale in the country than the town, and often remains in stock for a considerable time in the shops of local ironmongers until most or all the acid has escaped from it; but in towns it does not remain in stock nearly so long, and is consequently newer and more noxious to vegetation. This contingency is worthy of mention, for it is certain that old wire is much safer than new. Although the “escaping acid” theory of a practical man does not, to my mind, settle the question at issue in a satisfactory manner, it must not be altogether ignored, and it will be decidedly safer to use old wire than new, and especially that which does not bend freely, as its brittleness is evidence of its long immersion in the acid bath.

I pass now to another aspect of the case, and one that demands careful attention. Whatever injury may result from acid within the wire, I think it can be demonstrated that the branches of trees secured to zinc-coated wire are injured by the action of acid from without acting on the zinc surface with which the shoots are brought in contact. It is on this basis, and, so far as I can see, on this alone, that the different and conflicting statements that have been published can be reconciled, and this accord being effected we may hope to find an answer to the vexed questions—1, “Why is the wire injurious in some cases and not in others?” 2, “Why is the injury to trees so slight, or non-existent, in the pure air of the country, and so serious in situations where the atmosphere is impregnated more or less with the sulphurous compounds of smoke and vapours from ‘works’ and manufactories?” If these questions are not already answered, the following fact, which I think is indisputable, will complete the reply—namely, that sulphuric acid combined with zinc forms white vitriol—sulphate of zinc—which is a corrosive poison, and I will

further show that sulphate of zinc is the active agent of the injury under examination.

After the publication of the various letters on the question at issue, it was considered most desirable that a subject of such practical importance should not be left in the uncertain state it was. Different kinds of wire were therefore obtained last spring, to which the young laterals of Vines were secured in a small house in a decidedly “smoky district,” for it is within the sound of “Big Ben” of Westminster. The following were, briefly, the results:—1, New galvanised wire, serious injury. 2, One-year-old galvanised wire, slight injury. 3, Two-year-old galvanised wire, scarcely any injury. 4, Charcoal-drawn wire, no injury. 5, Copper wire, no injury. 6, Pure zinc wire, no real injury (but not put up soon enough). 7, Painted galvanised wire, new or old, no injury. Where the growths touched the new galvanised wire corroded specks were apparent in four days, and in a month the injury was severe, and was equally apparent on the shoots, tendrils, foliage, and berries that were placed in contact with it. Eventually the wire became covered with a thin film of oxide; as this increased the injurious power of the wire decreased, and towards the autumn the wire had little or no effect on the harder wood. Long before the autumn, however, and as soon as the effects of the different wire were apparent, the whole subject was considered, and I was supplied by Dr. Hogg with a packet each of oxide of zinc and sulphate of zinc with the object of proving the presumed safety of the former and danger of the latter. The results were exactly in accordance with the anticipations. On worsted being saturated with a solution of the former, tied round the stems and wires, old and new, and kept moist, no injury whatever followed; but on whatever kind of wire the sulphate of zinc was placed and the shoots attached to them, injury immediately followed, and this of a kind precisely similar to that communicated by the new galvanised wire. On examining laterals injured artificially with the sulphate of zinc with those affected naturally by the wire, no difference whatever could be detected between them; in fact, it was utterly impossible for anyone to whom injured portions were submitted to determine which had been injured artificially and which had sustained damage by ordinary contact with the wire. Some shoots that were girdled with worsted saturated with the sulphate of zinc were speedily killed, others that rested on the poisonous solution were only corroded on one side, the same as those resting on the wire. I am confident that whoever adopts the plan recorded will experience the same results.

We have here a few important facts in precise harmony with each other. Sulphuric acid combining with zinc produces sulphate of zinc—sulphate of zinc corrodes Vine shoots in contact with it; sulphuric acid is more abundant near cities and towns than in the country where there is little or no sulphurous vapour—injury to trees in contact with galvanised wire follows where smoke prevails, but is much less marked, when observed at all, where the air is quite pure; old wire covered with the protective and innocuous oxide is comparatively safe; new wire, especially near towns, is decidedly dangerous to vegetation that is in contact with it. These facts appear to point directly to the conclusion that the cause of the injury under notice is that above indicated, and, what is more, they do not seem to be so well reconcileable on any other basis that has yet been suggested.

I have examined the subject as closely, fully, and fairly as I have been able, with the sole object of eliciting the truth. Two years ago I was a disbeliever in the injurious effects of galvanised wire, now I am fully satisfied that it is, when new, highly dangerous in certain situations. It is, perhaps, too much to expect that all will agree with the conclusions arrived at; but those who differ will, of course, submit proof that the injury in question, that in many places has been so serious, has not resulted either from the escape of acid from the wire or the action of acid on its zinc surface, from a vitiated atmosphere.

Several letters relative to the injuriousness of galvanised wire have been received that it was not necessary to publish, as the writers simply repeated in substance what had previously appeared in the *Journal of Horticulture*, but extracts from a few of those letters may be given. "CIVIS" writes from Derby as follows:—

"Last spring I wrote two or three letters in your *Journal* calling attention to the injurious effect of galvanised wire for tying Peach trees, which called forth several replies disagreeing with my opinion as to the injurious effect upon the trees, notwithstanding I had all the galvanised wire removed and substituted copper wire instead; and no one need wish to see a better lot of trees in any house. They are full of flower buds and the wood ripened. I enclose you a small branch I cut off one of the trees that is tied to the back wall of my Peach house, and you will see for yourself the injurious condition of the wood. I found this branch had rested against a galvanised peg stuck in the wall, through which the copper wire ran. You will see it has eaten nearly through the branch, which in itself is a proof of damage the zinc wire will cause."

The injury to the shoot was very pronounced, and precisely the same effects are produced by placing a shoot in contact with sulphate of zinc, which corrosive substance forms on galvanised and not on copper wire. "W. E." writes from near Birmingham:—

"I planted *Habrothamnus fascicularis* in the border of a conservatory and trained it to galvanised wire. About a month after planting the leaves turned black and fell off, also the ends of the shoots were injured. I took it out of the border from the wire and potted it. When it had made shoots 2 or 3 inches long I returned it to the border. In a short time the same thing happened to it again. I again took it up and kept it in a greenhouse through the winter. The following spring I again planted it in the aforesaid border, but with the same results as before. I then had the wires painted, and the tree grew away amazingly. From observation I find that wire that has been in use some years to be harmless by being coated over with dirt, &c., which destroyed its injurious properties, and also think that the process of galvanising has something to do with it, some new wire being harmless and others very destructive."

Both the theories advanced receive confirmation from this letter. The coating of dirt, &c. (oxidation) preventing the sulphurous acid of the atmosphere of a smoky district acting on the zinc and producing the poisonous sulphate; while some "new wire being harmless and others very destructive," suggests that there is "something in" the mechanic's assertion that some wire contains more acid than others by a longer immersion in the bath, and that the acid afterwards "sweats out" and corrodes the plants. This view also applies to the following case. Mr. Allis writes from a presumably salubrious district, Bedfordshire:—

"Last spring I planted two houses with Peaches and Nectarines. The summer's growth was trained to new galvanised wire; the consequence is that many of the shoots are badly gummed. I have looked carefully through both houses, but I have not been able to detect a single instance of gumming except where the shoots came in contact with the wires. I have just had the wire painted with one coat of good white lead mixed with linseed oil. I am of opinion that one coat of paint is ample at one time, for this reason: If more than one coat is put on I am afraid it would scale off. Besides, it would be better to give the wires one good coat annually rather than two or three coats at one time, for at least two or three years. I have found that Cucumbers, Melons, and Tomatoes have been diseased where trained to galvanised wire. I have had my suspicions that Vines have been injured where the tender shoots have come in contact with the wire, but as a preventive I shall have all the wires painted with one coat of good white lead, and the walls with Carson's anti-corrosion paint, which answers the purpose admirably. We have tried it on galvanised wire, but it does not adhere to it."

This letter repeats a remedy that, so far as I know, has never failed; and it does not appear to be necessary to incur the expense of substituting copper for galvanised wire.

Mr. Geddes, writing from near Derby, attributes the injury

to the overheating of the galvanised wire by the sun. He states that

"The wires in a Peach house became so hot that no young shoot in contact with them could escape injury. I immediately had the wires painted with two coats of white paint, and a gentleman suggested that blue paint would be equally effectual. We painted again with blue, and never had a shoot injured since. Last summer we had two Peach houses painted. The painters painted the stout iron rods black, and every shoot that crossed those rods was burned; and by way of experiment a part was shaded from the sun and no injury followed there. Galvanised wire becomes too hot when not painted, and that is the sole cause of injury. Black or brown paint will not prevent the wire being heated; white will, as it is a non-conductor of heat."

That, as the Yankees say, is a "new notion;" but the overheating theory fails to answer the question that the wire under notice is injurious in some cases and not in others. The sun's heat is general, and is certainly as intense in the country as near towns—at Longleat, for instance, where galvanised wire is innocuous to vegetation, as near Sheffield and Derby, where its use is dangerous. Further, charcoal-drawn wire is black and safe; and old oxidised wire is much darker than new galvanised wire, while the latter, and lighter-coloured, is unquestionably the more injurious.

A Berkshire correspondent, "A. L. N.," writes as follows on imperfections in galvanising—

"Assuming for the moment that perforations in the zinc coating do exist—though they may, perhaps, be too minute to be visible with the naked eye—what will be their effect? At each one of them we have two out of the three requisites for forming a galvanic cell. We have the two dissimilar metals iron and zinc (the latter the most active ordinary metal that could be found for the purpose), and at some near point they are perfectly connected. The only thing, therefore, that is required for producing a slight local electric current is a drop of water, whilst a drop containing an acid will give a considerably stronger current. Drops of either kind may be supplied by the rain according to the situation. If they fall through the pure air of the country the raindrops will give feeble currents; if through the smoke-laden atmosphere of our towns they will have absorbed some of the sulphurous acid which is always present, and the action will be stronger. In either case its effect will be to dissolve some of the zinc, thus enlarging the uncovered portion of iron, which at first may have been a mere speck, till sooner or later it reaches some branch that is tied to the wire and subjects it to the fatal influence of the electric current. Several of Mr. Wright's facts tend probably to this explanation. He finds that—first, wire of the same metal throughout has no injurious effect (no galvanic action can here take place); secondly, more injury takes place near towns than in the country districts, because the rain contains acid in the former case; thirdly, immunity is obtained by well painting the wire—the paint closes the perforations and prevents the action. The alleged existence of free acid in the body of the wire is curious. If it is there and escapes in the manner stated, it would in doing so act more readily on the zinc than on the iron, and would thus produce the perforations in question. But independently of their being produced in this way, one would quite expect to find them, as zincing depends only on mechanically moistening the surface of the iron, which is itself far from homogeneous. Lastly, the almost passive condition which zinc assumes after exposure as compared with its chemical activity when bright and clean, would seem to account for old wire being harmless in cases where new would do mischief."

This is a very interesting letter, but whatever force the observations may have generally, they do not apply to the above-mentioned experiments, which, with four Vines out of the five, "not a drop of water" was applied to the wires. The Vines are grown under glass, and there is no leakage from the roof.

In purchasing new galvanised wire any that will not bend freely should be rejected. Unpainted and pliable wire may probably be safely employed in country districts where the air is pure, provided the wire is placed in water for a week before it is used for the extraction of any acid it may contain; but near towns and in manufacturing and mining districts the new wire cannot be regarded as safe if it is not well painted.

I wish to add that I have had the counsel of Dr. Hogg throughout this investigation, and I am indebted to him for valuable hints and suggestions in endeavouring to render an important and difficult subject plainer than it was before.—J. WRIGHT.

GARDEN REFUSE.—The articles on this subject that were published in your last volume were most timely, and another brief note will perhaps not be unacceptable. The accumulation of rubbish from various sources in different departments in a large

garden is considerable, which, when well incorporated with a slight admixture of quicklime, forms one of the best fertilising agents that can be employed for many purposes. Materials of this description do not usually receive sufficient attention. At times, therefore, when from the effects of frost or other causes the progress of ordinary work is interrupted, attention should be given to the materials which form the rubbish heap, turning them, and taking out such as are fit for use, and adding a little quicklime to what remains, well mixing it together in order to accelerate decomposition and furnish supplies as speedily as possible.—PRACTICALIST.

### STRAWBERRY FARMING.

(Continued from page 591, last vol.)

THE basis of all successful Strawberry culture, or of any other culture indeed, is a knowledge of the nature and habits of the plant we grow. I shall therefore shortly refer to them.

The botanical name of the Strawberry is *Fragaria*, and many species are found growing wild in both hemispheres. The typical European species is the Alpine Strawberry (*F. vesca*), the delicious flavour of which made it famous among the ancient poets. It does not appear to have been regularly cultivated for more than four hundred years, and during the earlier half of that period was very little improved from its native habit. It is peculiarly unaffected by cultivation, tending to reproduce itself with unvarying exactness. However, about 1727 a new species, more capable of improvement, was introduced from Chili (*F. chilensis*). Most of our modern varieties are the descendants of this. Strangely enough the other American species introduced about the same time (*F. virginiana*) seems to have been neglected for about a century, until its tendency to produce new varieties from seed was discovered. The Virginian Strawberry is the original of nearly all the famous varieties now cultivated in the United States.

It is to be noted that, in raising varieties from seed, we may find in the same batch three different kinds of plants—male, female, and bisexual, or perfect-flowered. This accounts for the occasional appearance of barren plants in our fields and gardens. Only the perfect-flowered varieties are worthy of culture, although good crops may be raised by planting those having pistils only, if every tenth row be occupied by either a staminate or perfect-flowered variety. The necessity for this precaution, and the consequent trouble and confusion, have led to the almost universal adoption of the bisexual-kind. Those who attempt hybridising, or allow seedlings to remain in the ground, ought not to lose sight of the facts. Even in perfect flowers, too, it is important to know that the stigma is ripe before the pollen on the same flower. Under proper precautions, therefore, it is comparatively easy to obtain a direct cross between selected varieties.

Besides producing seed the Strawberry propagates itself by forming new crowns and by rooted runners. Its seedlings are so unreliable we depend mainly on runners for new plants, though scarce varieties may also be propagated by dividing the crowns. The new crowns are produced year by year at the sides of those that have produced fruit, and soon after forming they emit new roots above the old ones, thus becoming almost independent of the parent stock. This habit accounts for the tendency of the plant to push itself out of the ground, and proves the absurdity of planting on the top of a ridge—a method too common in this quarter. In such a case the working of the ground and the influence of the weather soon deprive the plant of all chance of forming new roots. When, on the other hand, the plants are set rather under than over the level of the soil, an opportunity is afforded of year by year drawing in the soil so as to afford a chance to the new roots, and greatly prolonging the term during which a plantation may profitably remain.

Much difficulty is often experienced in selecting varieties suitable to particular localities. Perhaps no fruit seems so capricious in this respect as the Strawberry. The usual plan is to go on testing varieties for years till a suitable one is found—a wearisome and costly process. May not a little study of the habit of some varieties enable us to avoid in some measure such trouble? For instance, one variety is naturally strong in foliage, another only moderately so. The former will generally be found to fail in rich ground, the latter to thrive; while the opposite may be the case on poor soil. Again, some varieties, like Elton Pine, have long wiry roots that penetrate deeply into the soil, while others, like Rivers' Eliza, have short fleshy roots. The former will therefore thrive where the latter would starve, the one drawing its supplies from so much greater a radius than the other. Doubtless this property of the Elton Pine has led to its being the favourite in this district, where the soil is very poor. The other local favourites are likewise strong-growing deeply-rooted varieties, such as Excel and Rifleman. The tendency of a kind to

throw an excess of runners is also worthy of notice; for it may be taken for granted that if, after the first year, runners abound the fruit will be scanty. Of course, by constant pruning much may be done to remedy the evil, but on the whole it is better to select varieties with less erratic tendencies.

The character of the foliage should also be taken into consideration in selecting varieties. In shady cool localities the less heavily foliated forms are the best, as they allow the sunshine to act on the roots and flower buds; while in situations where the soil is light, and especially where there is a decided southern exposure, those with heavy foliage are to be preferred. The same selection should be made for localities more than ordinarily exposed to black frosts, the strong withered foliage being a necessary protection to the flower buds during winter; yet I have seen gardeners on the approach of winter shave their Strawberry beds with a scythe as close to the ground as possible, without even giving a mulch as an equivalent. Where late spring frosts are common it will often be found that varieties which, like Sir J. Paxton, throw their flowerstalks above their foliage are hopelessly blasted in a night; while others, like Excel, that hide their blooms under their leaves, escape. Such are a few of the considerations that should assist us in selecting varieties. Many others will suggest themselves to the observant.

A word more as to roots. Rooted runners continue to extend their rootlets from their extremities the first year until cold weather sets in. If these are to be transplanted in autumn they should be lifted very carefully and as carefully replanted without any root-pruning. Such plants will at once go on growing from the ends of the roots. The case is different with runners left till spring. By that time the roots have ripened, and will be mostly broken in the lifting. Such broken roots, like broken cuttings, do not throw out fresh fibres so readily as when cleanly cut. All spring-planted runners, therefore, should have their roots shortened by a sharp knife. The result will be a set of new fibres from the cut ends, and consequently a much stronger plant than if left unpruned. Such pruned roots should, however, never be placed in immediate contact with fresh manure, but be spread out in the moist soil.—WILLIAM RAITT.

(To be continued.)

### PROTECTING TEA ROSES.

THE old proverb of the uselessness of locking the stable door after your horse has been stolen has several times been brought to my mind lately on visiting the gardens of some of my friends. The last two winters killed nearly all their tender Roses. "They would be in time this year," said they; and early in November litter and mats disfigured their gardens. Up to now, the 5th of January, we have had very mild weather, and if in such weather we smother up our Roses and "coddle" our tender Teas woe betide us when the March winds and spring frosts come. I strongly advise my brother amateurs to have litter and matting and bags in perfect readiness, so that an hour's work will make all safe, but the policy of wrapping-up in mild weather on the chance of some day getting severe frost is a mistake.

Mr. George Paul says, "The fact is, we must 'watch' our Teas." This is quite right. We must thoroughly protect in severe weather, and when this weather changes suddenly we lovers of the Tea Rose must change our tactics, and remove from the immediate neighbourhood of our plants that light or heavy litter which if left close round them causes them to 'sweat,' and so to become a more easy prey to Jack Frost's next attack. I use cocoa-nut fibre. It is very clean, and easily moved with the hand. In half an hour I can cover or uncover one hundred trees. I have it about 8 inches deep. Many of my buds are starting on the Manetti. How precocious H.P. Lord Macaulay is! If this weather lasts much longer and we have a cruel spring untransplanted Rose trees will have a sorry time of it.—J. A. W.

### THE SEED ORDER.

I DON'T know how it may be with other gardeners, but making out the seed order with me is no small affair. True, it is simplified by practice, but I still spend many hours over it every season and return to it again and again. It is not that a packet or two of seeds, which may not turn out as well as the catalogues would have us believe, is a very serious affair; there are many things to be taken into consideration besides the actual purchase of the seeds. First, they cannot be grown without labour and room; and secondly, they may effect for good or for bad the successions which are expected to be kept up in all well-conducted establishments. When a man is spending his own money only he has a right to please himself in everything he buys, and if he is an enthusiast the interest he takes in his own experiments will to a

great extent compensate for any diminution of crop which may occur; but employers of professional gardeners know very little and care very little about the details of cultural experiments. A good supply of everything at the least possible cost is what they look for, and what those of them who allow sufficient means have a right to expect. What signifies it to them, for instance, whether a Bean has a white flower or a red one if the produce is equally good, or both? or whether the top of a Beetroot, which is not used for ornamental purposes, is black or green?

Possibly the craze for running after novelties simply because they are novelties is abating in some degree, but there are still many cases where novelties have the effect of pushing out standard things of sterling merit. Try promising novelties by all means, but my advice is, Never depend on them till you have proved them; there are now so many first-rate varieties of every kind of vegetable that a wrong selection is no excuse for a breakdown. Mishaps do occur, of course, in every place owing to a variety of circumstances under which we are at times helpless, but a seed order carefully made out and honestly executed will often do a great deal towards ensuring success.

I generally mark out first in pencil the quantities which I think are required at the margin of the catalogue, to be afterwards revised and corrected in ink as well as copied on to the order form. The catalogues so marked are carefully kept from year to year, and it is astonishing how the success or failure of the different crops will rise up before one's imagination as they are scanned over for the sake of guidance in the present selection. There is no need to refer to other memoranda, a figure signifying so many quarts of Peas or so many ounces of Onion seed will bring the whole crop very vividly before one's eyes, when judgment is easily passed on them even at this distant date. Last year I went out of my usual track in ordering Peas, as it was well known that all the better class of Marrows were imperfectly ripened, and consequently there were doubts about their germination. The splendid spring rendered these doubts almost groundless, but we cannot yet foretell the weather with certainty, and it is best to be on the safe side.

This year the seed is probably good (although I observe the best varieties are expensive), and if the exchequer will allow it we can again return to our favourite varieties. In naming those I grow I do not pretend to say they are the best for everybody; all I can say is that they are of good quality, they succeed well with me, and that I like them best of the varieties I have tried. William I. is as yet the best flavoured of the hardy very early Peas, and should not be discarded by anyone till he has personally proved another variety to be better. Last year for the second early I called in the services of an old friend which I had nearly forgotten, and was astonished at the quality of it; this was Eley's Essex Rival, and I mean to keep to it to provide two or three successions to come in between William I. and the real Marrow-fats. Among the Peas for general crops there are so many good ones that it is scarcely possible to be wrong in ordering any of them. Perhaps the most important thing to consider is the height, for when some of them grow 12 or 13 feet high, as they did last year, it is awkward for a short man to gather them, especially if he is in a hurry. I am still satisfied with G. F. Wilson and Veitch's Perfection for the main crop. I make several successions of them, and at each sowing two rows of each sort are employed. Generally speaking the middle of May is late enough to sow these.

For later crops the selection is a much more important affair, for good dishes of Peas in the end of October are reckoned among the best of dainties; and although the two varieties just named will often hold out very late in autumn if the weather is favourable, they are not quite so hardy as some other varieties to be specially recommended for that season. I have not yet seen a better late Pea than Ne Plus Ultra, but its height, which is 8 to 12 feet in good soil, is objectionable. Omega is nearly as good and is only 3 feet high, but I am afraid we shall not be able to have it again this season, and must fall back on our old friend with the Latin name and keep a pair of steps near. By-the-by, was the name given to this Pea in compliment to its height or to the season in which the crop is produced? About the 10th of June is the time here for making a last sowing of Omega. When earlier varieties are used they may be sown a week or a fortnight later. I do not remember seeing the Pea weevil during the past summer; did the previous wet year wash it away?—WM. TAYLOR.

**KING OF THE PIPPINS APPLE.**—In my opinion this is the best Apple in cultivation. This impression does not apply to any one particular merit, as it possesses every quality requisite in an Apple. In good seasons or bad seasons it never fails to produce a crop here. The fruit is extremely handsome in shape, high and

beautiful in colour, firm in flesh, and excellent in flavour. It is ready for use by the end of October or beginning of November, and retains all its qualities until March. I think it would not be easy to name another Apple which is in season for such a length of time; it is just as suitable for cooking as for dessert.—J. MUIR, Margam.

### SCIENCE IN HORTICULTURE.

AS the Potato disease has been ably and sufficiently discussed recently, and the matter remains very much the same as before, I will at present only refer briefly to the subject, which still remains a puzzle; and well it may do, for it defies all calculations and upsets all theories. Thus nothing has been more strongly insisted upon than change of soil. How, it is said, can ground which has become Potato-sick by having Potatoes grown on it year after year ever be expected to be free from disease? yet a short time ago I saw a man digging up in this parish, on a piece of ground which has grown Potatoes for thirty years and perhaps more, one of the largest healthiest crops of Potatoes I have seen this year, the ground, moreover, being moist and well manured, and in which last year there was considerable failure; while on my own ground, higher, of lighter texture, less manured, and after another crop, the failure was great. Does not this upset all the fine theories that have been set afloat concerning the Potato disease and the way to prevent it? If Science be all that it asserts itself to be, surely by this time we ought to have had something more certain than conflicting statements and fantastic directions as to culture.

I was very much amused the other day by reading in a contemporary a short statement on electricity as applied to horticulture. It was there stated that if a band of perforated zinc were placed round a plant and tied together with copper wire, a stream of electricity would be created which would shock the snails and slugs and prevent them doing anything so wicked as eating the plant enclosed by it. But this piece of cheap science is all fantastic. I have for years used the zinc collar without the copper wire and have found it quite efficacious in preventing their ravages. They seem to have a great objection to crawling over the rough surface of the zinc, and so, without even a chance of trying the electricity, keep clear of the plants.

Amongst the things which were impressed upon me from my earliest days of horticulture was that all pots in which plants were to be grown must be porous. Various scientific reasons were adduced why this was absolutely necessary. I was a little shaken in this when I recollected the slate tubs which Mr. Beck of Isleworth used; but all my early teachings were shattered when I saw this year the largest and healthiest collection of Auriculas I ever saw grown in highly glazed pots. Now the Auricula is not the easiest grown plant, yet here it was flourishing under conditions that were pronounced fatal to it. "Oh, but you will not find the roots coming out to the sides." Yes, I did, and apparently enjoying their position quite as much as in unglazed pots. I leave on one side the advantage or otherwise of this mode of treatment; but this is incontestable, that the plants flourish as well by this treatment as in the ordinary way, and here again science is at fault.

There was a great stir some time ago about carnivorous plants. We were assured that Dionæas, Sarracenias, Droseras, and such-like were furnished with a wonderful mechanism by which flies were caught; the plants fed upon them, increased in vigour as human beings would do on a meat diet, &c. This was denied by others; but as an ignoramus I should very much like to state that in going over Mr. Bull's wonderful establishment a little while ago I saw quantities of Sarracenia flava and Drummondii; the pitchers had indeed caught the bluebottles and other flies, but they had succumbed themselves, for they were all dead. Then, again, everyone who grows Heaths knows how the viscid varieties catch any number of flies—in fact more than any of the so-called carnivorous plants, and I never heard that anyone attributed any remarkable effect on the health from this strange diet.

Amongst other plants of which I have written a great deal in the Journal is the Gladiolus. Now here again I have been over and over again assured that I must not expect to grow it successfully in the same soil a second year; yet the most successful grower of them on a small scale I ever knew grew his for seven years on the same spot.

These are a few of the instances which have occurred to me, and which have certainly led me to the conclusion that when anything is very dogmatically put forward as to be accepted on scientific grounds I must "bide a bit." The story is well known of Charles II. puzzling his courtiers by asking why it was that a vessel of water weighed precisely the same when a two-pound fish was put into it as it did before. The savants set themselves to

give reasons, until one of the Court who did not lay claim to that title thought he would weigh it, and then he found the king had only been "poking fun" at them all. A little weighing and waiting will do no harm now-a-days.—D., *Deal*.

#### VARIATION IN TOMATO FRUITS.

HAVING seen a plant of Vick's Criterion Tomato at Norris Green bearing both smooth and corrugated fruits, Mr. Cox (page 8) has arrived at the conclusion that "fruits can be gathered from the same plant and exhibited as distinct varieties without much fear of disqualification." This deduction I consider doubtful, but in other respects his remarks are correct, as nearly all the medium and large-sized varieties are given to "variations and peculiarities," and the stronger and better they are grown the more apparent will this be. Propagating by cuttings, as Mr. Bardney suggests, will not affect the true characteristics of the variety beyond the first few fruits. The first bunches of blooms, both on seedlings and plants raised from cuttings, are often partially lost owing to a check—by late potting, perhaps, in the first case, and the process of striking in the other—being given to their development. The most forward blooms, and on some varieties frequently the next two or three that follow, on each bunch, are invariably much the strongest, the pistils frequently being fasciated; and from these result the fruits objected to by so many. Remove these blooms and the others will be benefited thereby, though by no means can the fruits be induced to grow so large as the mis-shapen fruit.

Unless I am much mistaken the lowest fruits on Mr. Bardney's plant were set from the last few blooms on the bunch, and the plant, having been considerably strengthened by good culture, produced stronger successional bunches, which in their turn bore some larger and corrugated fruit. If all the fruits were corrugated Mr. Bardney is not growing the true variety. To stage these corrugated and smooth fruit as distinct varieties would show either inexperience or but a poor opinion of the qualifications of the judges, who are acquainted, or at all events ought to be, with the eccentricities of the Tomato. Trophy and Stamfordian, which differ but slightly, are prone to produce ill-formed and handsome fruits, but no experienced person would think of sending the two examples as distinct varieties to the Fruit Committee of the Royal Horticultural Society. The handsome fruits might certainly be staged as Improved Trophy; but this will not avail, and properly qualified judges ought to be as expert as the majority of that Committee. Disqualifying is a disagreeable necessity, and it is not wise to give the judges an opportunity for resorting to it.

In conclusion it must be understood that these remarks are written in no controversial spirit—quite the contrary; and are simply offered to set Mr. Cox right and others who may think as he does.—W. IGGULDEN.

#### PRUNING GOOSEBERRIES.

FROM my youth I have been told by gardeners that Gooseberry trees ought to have their centres cut out, and ought to be trained outwards, low down, to produce the best and heaviest crops. Some six years ago I was taken ill and so affected that I could not stoop sufficiently low to gather Gooseberries from low bushes, so I determined to try and induce the trees to grow higher. I obtained some strong hazel rods, to which I had the leading shoots tied of each alternate Gooseberry bush. Next season every tied shoot produced a crop of Gooseberries hanging on it as closely as a rope of Onions.

The result has astonished many of my friends who have seen the trees in bearing, and I am now training upwards all the intermediate trees, for I find the side shoots "follow the leader," and in two or three years the bush becomes pyramidal and gives a much heavier crop for the ground occupied than when grown on the usual system. My bushes are now 4 to 5 feet high, and if I had not trained them upwards I should have had to cut out or remove a great many of them.—G. O. S.

#### MEYENIAS.

ACANTHACEOUS plants are as well known in our stoves and greenhouses and as much admired as the members of several other large natural orders in the same division of the vegetable world, which contribute to the attractions of such structures and of borders also. It is only necessary to mention the names of *Apheandras*, *Justicias*, *Eranthemums*, *Libonias*, and *Thunbergias* in support of this observation, for they all include species of considerable general value, easily grown, and characterised by brightly coloured flowers. To these may be added the small genus *Meyenia*.

which, though less popular than the others, is only so from the merits of its species being less widely known. It is closely allied to *Thunbergia*. One of the species is especially near to it both in habit and structure, but the other two are distinguished by their shrubby non-climbing habit. It has already been stated that the cultural requirements of the *Meyenias* are few; and it may be added that if a light rich compost of fibrous loam, peat, leaf soil, and a small proportion of well-decayed manure be employed, carefully draining the pots, and growing the plants in a brisk moist stove temperature, very little difficulty will be experienced in obtaining vigorous specimens that will flower satisfactorily. A position well exposed to light, and yet sufficiently shaded in hot sunny weather to prevent the foliage being scorched or the colour of the flowers deteriorated, is beneficial, with abundant supplies of water to the roots and over the foliage while growth is active. The plants have sometimes a tendency to become rather

Fig. 6.—*Meyenia erecta*.

straggling without a little attention is given to pruning the too greatly extended or bare shoots, but this is a matter that is very easily accomplished. As regards increasing the stock cuttings are readily obtained, and, if judiciously selected, usually strike readily in an ordinary propagating frame. The moderately firm wood should be chosen, as the tender extremities of the shoots are rather liable to damp off.

A few descriptive notes will suffice to indicate the respective characters of the species, commencing with the one represented in fig. 6, namely—

*M. erecta*.—A handsome plant of shrubby habit, with dark green leaves and fine axillary trumpet-shaped flowers, the corollas of which have a pale yellow tube, a throat of deeper yellow, and a rich purple limb. As the name implies it is erect in habit and has none of the climbing tendency which characterises the last-named species. It is a native of western Africa, where it was found near Cape Coast Castle by Dr. Vogel, after whom one of the species is named. Seeds, it appears, were sent to this country about 1855, from which plants were raised in several establishments and thence distributed. It is a really useful plant, as flowers are produced nearly all through the year—a quality which distinguishes it from the other forms. One variety is known in cultivation named *M. erecta alba*, which has white flowers with a yellow tube, resembling the type in other respects.

*M. Vogeliana*.—A species from the island of Fernando Po, in the Gulf of Guinea, whence it was imported about twenty years ago. It is very nearly related to the preceding species, but has large.

flowers, bracts, and leaves. The corollas are of moderate size, the limb being a rich purple hue, the inner surface of the tube bright yellow, and the outer white. It flowers during the summer months, and when in good condition is extremely handsome.

*M. Hawtayneana*.—This is also known as a *Thunbergia*, which it resembles, and it is, moreover, widely geographically separated from the other two species, being a native of the western portion of Hindostan. It has been longer known in this country than the other, for it had been some years in cultivation when a coloured figure of it was published in "Paxton's Botanical Magazine" in 1839. Dr. Wallich had, it appears, sent plants from Calcutta to England, and they had been grown by Messrs. Rollisson, at Kew and several other gardens; but the first to flower is said to have been the one figured by Paxton, which was in the then celebrated collection of Mrs. Lawrence. The plant is climbing, with opposite oval leaves and axillary flowers, the corolla being a deep bluish purple with a yellow tube about 2 inches in length. It is equally as attractive as the two already noticed, and as easily grown.—L. C.

## ROYAL HORTICULTURAL SOCIETY.

JANUARY 11TH.

THE first meeting of the year was exceedingly well attended by the members of the two Committees; and though the exhibits were not proportionately numerous, there were sufficient to render the Council-room very bright, Orchids, Primulas, Camellias, and Cyclamens constituting the chief portion of the display.

**FRUIT COMMITTEE.**—Harry J. Veitch, Esq., F.L.S., in the chair. Messrs. Saltmarsh & Son of Chelmsford again sent their new Apple The Queen, and after another examination the Committee decided that it is quite distinct, and confirmed the first-class certificate which was awarded. Mr. Woodbridge, The Gardens, Syon, exhibited a new Banana, one of a collection of eight varieties imported from Brazil. It grows about 12 feet high. The fruit is short and thick, and excellent in flavour, and the Committee highly approved it as to flavour and quality. Mr. Woodbridge also exhibited a good specimen of Telegraph Cucumber, to which a vote of thanks was awarded. Mr. J. Clark, Sycamore Gardens, near Farnham, sent a dish of Orangefield Dwarf Tomato, to which a vote of thanks was awarded. Messrs. James Veitch & Son exhibited two pots of forced Seakale, one the Lily White, and the other the old kind. The Lily White has already been certificated, and the Committee confirmed their approval of it. A collection of twelve sorts of Parsnips, which were grown at Chiswick under the following distinct names—Maltese, Guernsey Half-long, Student (three times), Elcombe's Improved Hollow-crowned, Hollow-crowned Improved, New Maltese, and Elcombe's; all of which were identical with the exception of Student, which was more fleshy than the others. One sort called Round Early was quite distinct, being round with a short taproot like a Turnip-rooted Beet.

**FLORAL COMMITTEE.**—Dr. Denny in the chair. Messrs. J. Veitch and Sons, Chelsea, contributed a group of Orchids, comprising nineteen species and varieties of *Odontoglossum*, among which the following were admirably shown:—*O. Alexandræ* was represented by a variety with very large pure white flowers, the lip stained with yellow and spotted with brown; *O. triumphans* very fine, richly coloured; *O. Andersonianum*, *O. pulchellum* with its spikes of small white flowers; *O. gloriosum*, *O. Pescatorei*, *O. nevadense*, *O. prænitenis*, *O. blandum*, *O. maculatum*, *O. anceps*, *O. tripudians*, *O. Roezlii* and var. *alba*, *O. Rossii majus*, *O. hystrix*, *O. Chestertonii*, *O. Coradinei*, and *O. crocidipterum*. In addition small plants of *Sophranites grandiflora* were flowering well and brightly. The dwarf *Leptotes bicolor* had numerous small flowers with a purple-stained lip, and *Oncidium auriferum* had a panicle of yellow flowers something like *O. cheuophorum*. The charming hybrid *Dendrobium endocharis* had about ten growths, each bearing a dozen white flowers, the plant not exceeding 9 to 10 inches in height. A vote of thanks was accorded for a plant of *Billbergia nutans*, with pendulous spikes of the peculiarly formed flowers marking the genus. A group of *Cyclamens* was exhibited, all the plants being extremely vigorous and well flowered, the whites pure and crimsons rich. The firm also staged a collection of small Conifers, *Retinosporas*, *Thuja*s, &c., showing the character of several handsome varieties. The *Retinosporas* were especially notable for their excellent colour. For all these collections a silver Banksian medal was deservedly awarded.

Mr. B. S. Williams, Upper Holloway, sent a collection of plants, chiefly Orchids, in very good condition. *Saccolabium giganteum* was particularly fine, two specimens bearing half a dozen spikes each. In one the rosy colour of the lip was particularly well marked, the sepals and petals being pure white. *Calanthe Veitchii* had three handsome spikes of flowers. *Dendrobium heterocarpum* had several fine flowers with pale yellow sepals and petals, the lip marked with rich brown. *Masdevallia tovarensis*, the pretty white-flowered species, was in excellent condition, and the diminutive *Masdevallia Wagneriana* was also shown. A silver Banksian medal was awarded. From the Society's gardens, Chiswick, a large collection of double Primulas was exhibited, comprising many particularly beautiful forms. Blushing Beauty (Henderson), white faintly suffused with pink, and King

of Purples (Henderson), rosy purple, were noteworthy for the good size and form of the flowers. Gilbert's Mrs. Barron is also a handsome variety with large white double flowers profusely borne. Mr. George, gardener to Miss Nicholson, Putney Heath, was accorded a vote of thanks for a collection of *Abutilon* flowers of excellent form and rich colours. Mr. H. Boller, Kensal New Town, was similarly honoured for a collection of diminutive succulent plants. Messrs. W. Paul & Son, Waltham Cross, Herts, exhibited nine boxes of *Camellia* blooms in remarkably fine condition. The varieties chiefly represented were the old and beautiful *alba plena*, *imbricata*, *Halleyi*, *Marchioness of Exeter*, *Jeffersoni*, *conspicua*, *Eclipse*, and *Montironi*. Other varieties were shown, but in smaller numbers; of these the most notable were *Princess Charlotte*, *Linda Rosazza* good in form, *Aulica*, and *Reine des Fleurs*. A box of Tea Roses was also shown, comprising neat buds of *Safrano*, *Madame Falcot*, *Niphetos*, and *Isabella Sprunt*. A silver Banksian medal was awarded.

Mr. H. Cannell, Swanley, Kent, staged cut blooms of some Zonal *Pelargoniums* of extraordinary merit. They included the following:—*Olive Carr*, pink, very large, and of good form; *J. B. Miller*, brilliant scarlet, enormous size, petals very broad and excellent form; *Aida*, white tinged with pink, very distinct and delicate; *Colonel Seely*, very deep rich scarlet, fine form; *Romeo*, rich scarlet, large; *Dr. Denny*, a most distinct variety, warm purplish tinge; *Mrs. Strutt*, pale pink, large flowers; and *Mrs. Moore*, scarlet centre and white petals, all handsome. Primulas were also well shown, *Lilacina*, *Swanley Red* and *Swanley Purple*, being in admirable condition.

First-class certificates were awarded for the following plants:—

*Carnation Andalusia*.—Mr. Hill, gardener to Sir N. de Rothschild, Tring Park, Herts, obtained a certificate for this variety as a decorative plant. It is one of the tree section with pale yellow flowers very full, of good size and form, the petals elegantly fringed. It appears to be of free growth and profuse in flowering.

*Vanda lamellata Boxallii*.—Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Streatham, was awarded a first-class certificate for this variety, which has small flowers, the three upper divisions of the perianth being white, the lower streaked with rich brown, and the small lip bright rosy purple.

*Pelargonium Eureka* (Cannell).—A pure white Zonal variety. Flowers of good form, originally exhibited under the name of I've Got It; very good in habit, robust, and free in flowering. A handsome variety, and one of the best whites in cultivation.

**SCIENTIFIC COMMITTEE.**—Mr. Boulger exhibited and described a series of models of carnivorous plants made by R. Brendel of Berlin, and under the direction of Professor Cohen, admirably adapted for class purposes. Some discussion followed on the nature of the pepsine and peptones discovered in plants, in which Professor Church and Dr. Gilbert took part; the former observing that peptones are found in Lupin seeds and not as the result of a ferment, Dr. Gilbert observing that such was the result of defective ripening. Dr. Masters exhibited a specimen of Twitch, *Triticum repens*, which had penetrated through a Potato.

*Chinese Passion Fruit*.—An orange Solanaceous fruit sold in the markets under the above name, is fruit of a species of *Cyphomandra* (*Solanum betaceum*). Mr. Noble of Bagshot, forwarded a plant of *Abies lasiocarpa* grafted on a Silver Fir, which being in a diseased state had produced a large cork-like knob at the point of union.

**LECTURE.**—The Rev. G. Henslow commenced his lecture by describing the methods by which *Cyclamen* buries its pods, as detailed by Mr. Darwin in his new work on the movements of plants, and observed that it afforded a hint to horticulturists to supply the growing fruit pods with nutritious matter which could be absorbed by them. He also described the burying of the fruit of *Trifolium subterraneum*, which exhibited "aggregation" of the protoplasm in the cells of the hairs of the calyx, implying a power of absorbing nutritious matter, and confirming the remark he made in last lecture on a similar absorptive power discovered by Dr. Masters in the nectaries of the Hellebore, that probably all plants can absorb nitrogenous matter if presented to their surfaces in a suitable manner, and possibly this would prove to be one if not a chief use of plants being so often hairy when growing in dry localities. The lecturer also described the circumnutating process of hypocotyls when the germinating seedlings are issuing from the ground.

Collections of single and double *Primula sinensis* furnished the substance of remarks on intercrossing of flowers illustrating heterostylism, while some cut flowers of *Abutilon* were remarkable for their strong proterandry, a phenomenon also shown by *Pelargoniums*. These peculiarities, however, were not absolute but relative, inasmuch as *P. sinensis* is very liable to become homostyled in having the pistil of the same length as the stamens, while *Pelargonium* may so shorten the time between the maturation of the stamens and pistil as to render the flowers self-fertilising. Mr. Darwin mentions the curious fact, that while of most other Primulas the short-styled form is most self-fertile, in *P. sinensis* it is the long-styled form, and this is perhaps attributable to the fact that the corolla on falling off drags the anthers over the stigma and so secures fertilisation. A group of Cactaceæ and succulent Euphorbiaceæ illustrated representative plants, the quaint forms of the former of Mexico being exactly paralleled by those of Euphorbia in Africa, though the structure of the flowers showed they had nothing else in common than their general physiognomy.

As a further illustration of this fact, the lecturer described with the aid of diagrams the strong proterandry of *Malva sylvestris*, and the self-fertilising method of *M. rotundifolia*, both, as well as *Abutilon*, being of one family—the *Malvaceæ*. The double-flowered *Primulas* supplied material for a few remarks on the different methods of doubling, such as conversion of carpels and stamens into petals, and their multiplication; or by the development of an extra corolla called catacorolla, or by conversion of stamens only into petals, as occurred in the double Cherry; or carpels only, the stamens remaining normal, as in *Anemone*, &c.

A collection of *Camellias*, which botanists now regard as identical with the genus *Thea*, suggested that the leaves should be roasted and a decoction made from them to see if a palatable tea could be yielded by them; for it is said the common Holly is used as tea by the peasants in the Black Forest, and there is another species of *Ilex* of which *Ilex paraguayensis* is a second. This latter furnishes the Paraguay tea of South America.

### VEGETABLES NEW AND OLD.

THE year 1880 will be remembered by many on account of the unusual abundance of vegetables. To all but the growers for the markets this remembrance will be an agreeable one, as private gardeners and others have not for some years obtained such an abundant return for their many weeks of intelligent care and labour. Unfortunately to market growers over-abundance generally means a profitless season, as they cannot afford to grow vegetables for sheep-feeding, to which use immense quantities of some kinds have necessarily been applied during the past season. Private gardeners have not much to complain of generally, though many doubtless lost the greater part of their Potatoes by disease. Others have had their Celery much weakened by the larvæ of the Celery fly, and still more have good reason to lament the disfigurement of their Carrots by the maggot. On the whole, however, failures were few, and should there be no severe frosts this winter those vegetables in season will be abundant and good.

Brussels Sprouts have apparently been planted, both in private and market gardens, in much greater numbers than heretofore. This is as it should be, as there is not a more reliable or more profitable crop grown. In 1879 we read many complaints of the failure of Brussels Sprouts to "button." Several reasons were given for this; some suggesting that late sowing and planting, and others that faulty stocks of seed, were the primary cause of failure. To a certain extent both may have been correct in the respective cases, as there is no doubt that if heavy crops are required early sowing and early planting must be practised, and it is equally certain there are some superior stocks of seed. At the same time I am inclined to think the true cause of failure lay in the preparation of the soil and planting. Planting thickly and in a rather loose rich soil almost invariably encourage excessive growth, and the reverse of what should be aimed at. I took a lesson from the market growers, and raise the plants as sturdily as possible, plant early on firm moderately rich ground, placing the rows 3 feet apart and the plants 2 feet asunder in the rows, and invariably secure good crops. I was at one time under the impression that cultivation alone affected the heavy or light cropping habits of the Sprouts, but find that the Aigburth Sprouts are undoubtedly superior to any I have tried.

Cauliflowers during the past season were particularly good, though at times much infested with caterpillars. I grew three "extra earlies," and as they were apparently identical shall merely recommend that an extra early be grown in every garden. They may be planted thickly, say 15 inches apart each way. I never allow more than 18 inches each way for the largest varieties of Cauliflowers, and cannot understand others giving more room when many more smaller and appreciable heads can be had from a given space. Dean's Snowball is one of the best Cauliflowers I have grown; it is very compact in growth, the heads of medium size and very close, and it can be had good up to July and August. The Dwarf Erfurt Mammoth is still worthy of a place in every garden. Carter's Mont Blanc follows this, and still later Suttons' King of the Cauliflowers comes into use. Both are valuable also for the autumn supply. I find Dicksons' Eclipse a good early autumn variety; but the stock is scarcely fixed, as my batch of plants included at least two distinct varieties, one resembling a good Walcheren Cauliflower, and the other Veitch's Autumn Giant, though scarcely so well protected as that variety, but is rather earlier and will be grown on that account. The Autumn Giant was particularly good. Some that followed Potatoes and were planted in the second week in July on a south border have continued to yield a number of small heads up till now (January 5th), care being taken to closely cover the heads with the oldest leaves.

Broccoli in the open failed completely in many districts, even where allowed abundance of room. Veitch's Autumn Broccoli,

although scarcely so good as I read of others having it, produced a number of small useful heads; as also did Snow's Winter White. Both require protection during a severe winter. At the present time I have both very good in the open. Osborn's Winter White is my ideal of a good Broccoli, being dwarf and close-growing, therefore hardy; heads medium size, white, and well protected. It is fit for use early in February or later according to the season. I had no novelties for trial, and have only to state that I find Knight's Protecting, Leamington, Cattell's Eclipse, and Suttons' May Queen excellent varieties, which come into use in the order named.

Of Cabbages I find Hill's Dwarf Incomparable (Osborn & Sons) to be most profitable; it is compact in growth—indeed they only require 15 inches each way—and the conical heads are of good size and quality. Carter's Heartwell is the best of the larger varieties. Rosette Coleworts are now very useful and good. Savoys came in too early, and were of less value accordingly. I consider Little Pixie, Early Ulm, and Drumhead a good selection.

Celery has been particularly good this season, the only exception being the earliest sown, nearly the whole of which decayed at the hearts in an unaccountable manner. They were raised in heat (not fire heat), pricked out on a slight hotbed, and gradually grown into sturdy plants. They grew well in the trenches, were never to the best of my knowledge dry at the roots, and were carefully earthed up. When examined early in September prior to lifting for use what should have been good Celery was worthless. The variety grown was Williams' Matchless Red, which in previous seasons has proved exceptionally good. Later sowing of this, Carter's Incomparable Crimson, Major Clarke's Solid Red, and Leicester Red have all turned out most satisfactorily. The two latter differ but slightly, and I have no preference for either of them. We generally sow the principal part of our Celery seed, and also Celeriac or Turnip-rooted Celery, thinly over a large shallow hotbed, thinning out the seedlings where crowded, and transplanting direct into the trenches as the selected ground is cleared of Cabbages. We plant the Celeriac on well-manured ground which was previously occupied by the second early Cauliflowers. They are planted on the level, allowing the plants 15 inches apart each way, and are watered during very dry weather. The roots that follow are rather larger than cricket balls, and are much appreciated during the winter.

Beet had a tendency to coarseness. Fortunately the greater part of our seed was sown late (May 5th), and we therefore secured enough of the requisite medium-sized roots. Osborn's Select (Dell's Crimson) was good in every respect. The Turnip-rooted Beet was much the earliest, and was unusually good in colour. I do not store any of this, but it saves the main crop and deserves to be generally grown. Carrots, as before stated, were very maggoty, wood ashes apparently failing to act as a preventive. The Nantes Horn, James' Intermediate, and Altringham form a good selection.

Turnips have been very plentiful and good. With us the Purple-topped Munich was ready for use some days before any other variety, and is for that reason valuable. It was inferior in quality to Suttons' Snowball and Carter's Jersey Lily, both of which are excellent early varieties, and also suitable for autumn sowing. Carter's Golden Rose is, I find, good for autumn sowing; the flesh is orange yellow in colour and of excellent quality. Mitchellson's Market Jew, kindly sent to me by Mr. W. Roberts, is a large quick-growing variety, in some respects resembling the Green Round. The flesh is pale yellow in colour and of good quality, and the variety is much liked, I am informed, by the Cornish market growers. The Jews have a partiality for yellow Turnips, and great quantities are sent from this district to the Spitalfields market for them.

Peas were both abundant and good, but they grew to a greater height than usual, and we found it necessary in some instances to top them, as the pods filled badly. Harbinger was ready for use a week before William I., was of good quality, cropped heavily, and from near the ground. It attained 4 feet in height, while William I. reached 5 feet. The latter was very profitable, and will be sown again with Harbinger. The second sowing of these varieties was closely followed by Culverwell's Telegraph and Carter's Telephone, both varieties cropping heavily, the pods being large and well filled with peas of excellent flavour. The succession was maintained by Carter's Pride of the Market and Stratagem, which may be described as good dwarf forms of Telegraph and Telephone respectively. A great favourite of mine—Huntingdonian—fully sustained its reputation as a good tall second early variety, and the same remarks apply to Carter's Little Wonder as a dwarf variety. Neither Dr. McLean nor Sharpe's Invincible did well on our rather cold soil, but some of the latter I gave to a friend for a light soil succeeded admirably.

Webb's Triumph, described as a 4-foot Pea, grew 7 feet in height, but did not prove very profitable. On some soils it may be found a good main-crop variety. Laxton's Marvel succeeded admirably, cropping heavily, the long pods being closely filled with very sweet peas. A still finer Pea is Laxton's John Bull, and both this and Marvel are suitable for the main crop, especially where medium-height varieties only are grown. I cannot speak in favour of Laxton's Baron. It grew luxuriantly and cropped heavily, but the very large pods filled badly. Suttons' Duchess of Edinburgh is a very profitable tall Pea suitable for main crop. It is one of the best-flavoured Peas grown. I find Veitch's Perfection and Ne Plus Ultra two good varieties for the latest supply.

Of Broad Beans we grow but few. Early Longpod and Hardy's Pedigree Windsor are two profitable varieties, and for exhibition purposes none are equal to Carter's Leviathan.

Kidney Beans were very productive, none more so than Osborn's Forcing, which is still the best early variety. I found it advisable to stake Canadian Wonder, and was rewarded with an abundance of very long tender pods. Monster Negro cropped well in frames and in the open, but I failed to discover in it any very marked improvement on the old Negro Longpod. Carter's Advancer was again very productive and good. Runner Beans produced extra heavy crops. The Scarlet Champion and Giant White were grown. Parsnips, owing to the wet season, were much cankered. The Student is my favourite.

Onions were inclined to be "bull-necked," but they give promise of keeping well. The White Naples or the Early White Italian are particularly good for autumn sowing, as they bulb early the following spring and their mild flavour is much liked. The Trebons and Giant Rocca are also suitable for autumn-sowing, as if well ripened they will keep till midwinter. For summer sowing I like the Improved Banbury, good substitutes being the Improved Reading, Pinesfield Improved White Spanish. James's Keeping and the Brown Globe are the best keepers. I find the Round or Summer Spinach quite as hardy as the Prickly or Winter, and this autumn the seed of it germinated more freely.

Tomatoes cropped very heavily, but many of the fruit was diseased. Some of the most profitable were Early Gem, Earley's Defiance, Acme, Conqueror, Vick's Criterion, and Vilmorin's Early Dwarf. Remarks on Potatoes must be deferred.—W. IGGULDEN.

## NOTES AND GLEANINGS.

At a General Meeting of the ROYAL HORTICULTURAL SOCIETY held last Tuesday, Sir Trevor Lawrence, Bart., M.P., in the chair, the following candidates were duly elected Fellows of the Society—viz., Lady Lavinia Bertie, Mrs. Bret-Ince, A. Crowfoot, Wolf Harris, Mrs. Miller, Mrs. Frank Morris, Mrs. Edward William O'Brien, Mrs. John Park, Arthur Pease, M.P., J. P. Pike, J. Rattle, Mrs. Sheepshanks, Rev. — Howard, and A. Watson; George Duffield, and Mrs. Rubens, were elected Guinea Members.

— SNOW FELL IN LONDON on Tuesday night to the depth of about 2 inches—the greatest fall in the metropolis during the present winter.

— THE following are the names of the gentlemen elected to serve on the COMMITTEES OF THE ROYAL HORTICULTURAL SOCIETY for the present year, in the place of some retiring members:—*Scientific Committee*—John Ball, F.R.S., G. S. Boulger, W. Carruthers, H. J. Elwes, F.L.S., F.Z.S., F. P. Pascoe, F.L.S., and Sir W. C. Strickland, Bart. *Fruit Committee*—J. Burnett, F. Campion, John Lane, Major F. Mason, T. Francis Rivers, Sir C. W. Strickland, Bart., and Jesse Willard. *Floral Committee*—John Burley, G. Duffield, Henry Eekford, Andrew Henderson, Maxwell T. Masters, M.D., F.R.S., Robert Parker, and J. Roberts.

— WE regret to announce that A FIRE BROKE OUT AT THE FULHAM NURSERIES of Messrs. Osborn & Sons about 11 o'clock in a packing shed which contained a quantity of dry hay, straw,

&c. The shed was partially destroyed and all that it contained. Fortunately there was not much in at the time for packing. The fire was subdued before reaching the office and seed shop adjoining, but in the meantime the mob which had collected dragged out bags of seed and anything they could lay hands on. The consequence was a quantity of seed was lost, as many bags were open at the mouth, and many were split open from rough usage. Many other sundries connected with the seed business were also lost or broken. The plants in the adjoining greenhouse also suffered to some extent. Had the wind been blowing from a southerly direction the whole of the buildings must have been destroyed. The cause of the fire is unknown. We are pleased to learn that it will not interfere with the general routine of business, but the execution of seed orders will necessarily be delayed about a week.

— AT a meeting of the ROYAL BOTANIC SOCIETY, Regent's Park, held on Saturday, Mr. Beresford Hope, M.P., in the chair, a long list of donations of plants, seeds, &c., received since the last meeting was read, including seeds of African Copal from Zanzibar, and of the Talipot Palm from Ceylon.

— MR. R. INGLIS sends the following note—"The total RAINFALL during 1880 at BORDER HILL (Mid-Sussex), was 36.16 inches. Only 10.21 inches fell during the first six months. The driest month was May, and the wettest month October, 0.37 inch in the former, and the unusual large quantity of 8.24 inches in the latter. Rain fell on 152 days. The autumn has been remarkably fine and open. The mercury fell below freezing on three occasions in October, twelve in November, and seven in December, mostly slight frosts, the lowest being 23° Fahr. on November 17th."

— WE had last week to inform our readers of the death of a noted horticulturist, and we have now the same unpleasant duty to perform. Mr. CHARLES EDMONDS, who is so well known for his long period of service as gardener at Chiswick House, died in the commencement of his seventieth year on the 30th ult., at Llandudno. The deceased was for many years one of the Council of the Royal Horticultural Society, and frequently officiated as judge at metropolitan exhibitions.

— WE have received the schedule of the SUTTON COLD-FIELD ROSE EXHIBITION, which contains seven sections and twenty-three classes. Twelve prizes are offered in the nurserymen's classes, ranging in amounts from £5 to 10s. In the amateurs' classes silver cups are offered for thirty-six and twenty-four blooms, distinct. Four and five prizes are provided in the local amateurs' classes, and special prizes are offered by J. McLeland, Esq., Messrs. Cranston & Co., and Mr. George Paul. The Exhibition is to be held on July 22nd, in the grounds of the Crystal Palace Company, which are close to the stations of the Midland and London and North Western Railway. The Rev. J. A. Williams, Yardley Wood Vicarage, near Birmingham, is the Honorary Secretary of the Rose Show, to whom all communications and entries should be addressed.

— THE annual general meeting of the METEOROLOGICAL SOCIETY will be held at 25, Great George Street, Westminster, on Wednesday, the 19th inst., at 7 P.M., when the Report of the Council will be read, the election of Officers and Council for the ensuing year will take place, and the President will deliver his address.

— WE are informed that the MEXICAN POTATO, which is a variety cultivated by Capt. Mayne Reid of Frogmore House, Ross, Herefordshire, raised by him from seed obtained from Mexico, and is said to be unaffected by the disease, has passed into the hands of Messrs. J. Cheal & Sons, Crawley, Sussex. We gave

some time since a description of the variety in the words of the raiser.

— WE have previously referred to the enormous importations of American Apples, and it appears that the APPLE TRADE IN CANADA is annually assuming greater proportions, which may be gleaned from the fact that up to the 13th ult. 126,633 barrels had been shipped from the port of Montreal alone to this country. This number exceeds last year's exports for the same period by 76,849 barrels, besides heavy shipments *via* Boston and New York.

— THE weather is now very WINTERLY NEAR LIVERPOOL; sharp frosts have prevailed since Thursday last, varying from 8° to 14° below freezing. The trees are densely covered with white rime, and look most beautiful. The sun has not made its appearance during these days of frost, and forcing operations have to be conducted with much care.

— REFERRING to Pettigrew's CARDIFF CASTLE CUCUMBER "AMATEUR" writes—"In several trade catalogues I find a Cucumber bearing this name offered as being 'one of the best in cultivation.' As it is new to me, I should be glad to know what are its chief recommendations, and in what way it differs from Telegraph or any other well-known leading kind? Is it a distinct cross, or is it only one of our old varieties under another name?"

— WE learn that Her Majesty's Office of Works has entrusted Mr. Anthony Waterer of Knap Hill Nursery, Woking, with the providing and planting of a large number of RHODODENDRONS AND AZALEAS IN HYDE PARK during the approaching season. The plants are well set with bloom buds, and with fair weather it is believed they will make a fine display in Rotten Row.

— ON the 8th inst. the Rev. H. H. Higgins of Rainhill delivered an excellent LECTURE ON THE CULTIVATION OF MOSSES to the members of the Liverpool Horticultural Association. The lecturer treated largely upon native as well as many tropical species, and illustrated with diagrams many different varieties, minutely explaining their botanical construction. Mr. Higgins is well acquainted with Mosses, and at one time cultivated about 220 forms, each grown in a separate pot and grouped in a large Wardian case. The lecture was much appreciated by the members of the Association. Mr. Bardney also read a paper on "Hybrid Perpetual Roses in Pots," principally for forcing. The meeting terminated with the usual vote of thanks to Messrs. Higgins and Bardney, also to Mr. Halhead, the Chairman of the meeting.

— As will be seen by an advertisement in another page, it has been proposed to raise a GARDENERS' MEMORIAL TO THE LATE MR. ARTHUR VEITCH. It is intended, if sufficient subscriptions can be obtained, to institute a fund for the Gardeners' Benevolent Institution, to be called the Veitch Memorial Fund. No doubt the general respect entertained for the deceased gentleman will induce many gardeners and others to give substantial support to this excellent proposition.

— "W. J. M." writes respecting HOLLY BERRIES IN IRELAND—"I can confirm the truth of Mr. Campbell's observation as to the scarcity of Holly berries so far as this locality is concerned, and my correspondents in other districts invariably say the same. This scarcity is not confined to Holly; Arbutuses, Aucubas, Kalmias, Cotoneasters, and Pernettyas, where grown outside in sheltered situations, are equally deficient. The absence of berries and the lingering growths of the more tender shrubs I believe must be credited to the terribly severe check sustained from the winter of 1878."

— WE are requested to call the attention of our readers to

the sad circumstances attending the death of the late THOMAS TUCKER, foreman packer, for eighteen years in the employ of James Carter & Co. By his sudden death his widow with a family of six children are left utterly unprovided for. A few friends and fellow workers have subscribed a fund for temporary purposes, and a Committee has been formed to receive subscriptions from anyone desirous of helping the family. Contributions will be thankfully acknowledged by any of the following members of the Committee, and should be addressed to them care of Messrs. James & Co., High Holborn:—A. H. Dunnett (Hon. Treasurer), C. H. Sharman (Hon. Sec.), W. G. Sharman, A. Ainsworth, W. H. Hayward, W. F. Cuming, J. Comont, H. Ingrey.—Old "Show" hands will remember Tucker.

— WE are glad to learn, says *Nature*, that Prof. MacOwan, late of Gill College, Somerset East, has accepted the post of Director of the Botanic Garden, Cape Town. He will also lecture at the South African College. The appointment of a man whose long and enthusiastic devotion to South African botany has earned him a wide reputation is to the credit of the Cape Government, and is of good omen for the scientific future of the Cape Botanic Garden. This has never yet attained the position which it would naturally derive from the resources of one of the most interesting floras in the world.

#### FORWARDING EARLY PEAS.

PEAS cannot be had too early, and various means are adopted for advancing the crop. November-sown Peas sometimes come in the earliest, and in other cases they are behind those sown in spring. If outdoor culture is exclusively followed the autumn-sown Peas might be the first in most instances, but if a little extra attention be given to spring-sown Peas they will be the most satisfactory. I think it would astonish many if it was only known the quantity of seed that is lost through various causes by November sowing, and the patchy rows we often see in spring promise anything but a full and abundant crop. Mice and other vermin are more destructive on these than those sown at any other time, and it is generally before the growths come through the soil that the injury is done. From this it may be inferred that if early Peas were sown under protection, and planted out after they had grown a few inches, losses or blank rows would be nearly unknown. This is my opinion, and of all ways of forwarding early Peas I think there is none better than sowing the seed under cover and planting out.

I have tried many ways of raising young Pea plants—such as sowing them in turves, in tiles, old waterspouts, boxes, &c., but I never found them do so well as in small 3-inch pots. Sowings made in two or three hundred of these supply plants to make several fine rows. No drainage is put in the pots, but a little rough manure is placed at the bottom of each, and then rich soil is rammed firmly over this until the pot is about three parts full, when from eight to twelve peas are placed in each and covered with a little more of the soil. They are then placed close together in a cold frame or cool house, and no water is given until the growths are seen. These soon appear, and water is supplied afterwards as it may be required. They are placed as near the glass as possible, but never in forcing heat, as this would weaken the growths and entail labour in having them "bordered off," besides running great risk of giving them a severe check while undergoing the operation. Air is admitted on all favourable occasions until they are large enough and the weather permits their being planted out.

When the time comes for this the pots are well filled with healthy roots, and planting is done without injuring a leaf or root. All our best spring and early summer Peas were raised in this way last year, and I never had better. The labour required is inconsiderable compared with the advantages. In planting we do not place the potfulls as close together as they will stand in, but each little tuft is planted about 6 inches from the other. Before they come into fruit they look as if they were or had been originally packed in close together. If a little old potting soil can be placed against the roots at planting time it assists them in growing. The stakes are placed into them at once, and if the situation is bleak or the weather cold a few Fir branches or Laurel trimmings are put in here and there for shelter.

With valuable Peas it is a bad plan to trust the seed in the ground early in the season, as from various causes many may fail,

but if the plants are raised in pots all dangers of the kind cease. In fact all our new Peas are raised in this way whether they are wanted in spring, summer, or autumn, as many of them can only be had in small quantities.—A KITCHEN GARDENER.

### THE QUEEN APPLE.

THIS very fine new culinary Apple is referred to in our report of the Fruit Committee on page 26. The fruit is medium-sized; oblate, even, and regular in its outline, and ribbed round the eye. Skin clear lemon colour, almost entirely covered with bright crimson, which is again marked with broken streaks and patches of dark crimson, and with a lining of russet in the stalk cavity. Eye half open, with long erect slightly divergent segments, set in a deep and ribbed basin; tube short conical; stamens median. Stalk nearly three-quarters of an inch long, deeply inserted in

Fig. 7.—Apple The Queen.

a wide and deep cavity lined with russet. Flesh white, tender, very juicy, with a mild acidity. Cells of the core open.

A fine culinary Apple, in use from October to January. Very handsome.

This received a first-class certificate from the Royal Horticultural Society, November 16th, 1880. The seedling was raised twenty-two years ago, with three others growing beside it, from the pips of one Apple, but the parentage is unknown, as the Apple was purchased in the market. It first bore fruit about the time of the famous Tichborne trial, and was originally called The Claimant. It is larger, handsomer, a better keeper, and more productive than Cox's Pomona.

### SELECTION OF VEGETABLES.

IN reply to Mr. Brotherston on page 5, I can hardly say what proportion of the Peas named should be sown, unless I knew what demand there was for Peas at any particular time; but as the seasons of all are stated, everyone can sow one or all to suit their circumstances. Supposing Peas were wanted throughout the season, I would sow one quart of William I. for an early crop; one quart of Stratagem, two quarts of Telephone, and two quarts of Telegraph for main crop; and one quart of Omega and one quart of Ne Plus Ultra for late supply. According to our thin and improved way of sowing, this quantity would make close upon 400 yards of Pea rows at the lowest calculation, and this length would yield an enormous quantity of Peas. In speaking of economy Mr. Brotherston must have been thinking of the price of the seed of some of these Peas, but that is nothing compared with their produce, which should be taken into consideration. I know that quarts could be had of some varieties at a less cost than pints could be bought of others; but, on the other hand, peeks of pods would not be had from the former to bushels from the latter. I have tried them all, and am as fond of economy as anyone, but I do not think there is much of this in buying an inferior packet of seed for 6d. if superior could be had for 1s.—J. MUIR.

HAVING for a length of time read your valuable Journal, not without benefit, I venture to ask a few questions relative

to the "trustworthy selection" of vegetables given by your correspondent Mr. Muir on page 592 of your last volume. Those that I would be glad to have further information about before depending upon them for a main crop are the following:—Is Giant White Runner Bean of a good green colour when cooked? Ought I to depend upon Shorthorn Carrot alone? May I sow Cabbage Lettuce—Wheeler's Tom Thumb—as the only source of salad for the season? having never grown it, I wish to ask if it is as good in flavour as a Cos variety? Is William I. a good main crop Pea? I have not grown the Green Gage Tomato; is it reliable when only one is grown? The vegetables named and the Custard Marrow are accorded the place of honour—that is, "first named," being those recommended where only one variety of a kind is wanted. A good selection of vegetables at the present time is of great assistance to a beginner, and I shall be grateful to Mr. Muir or to any other of your able correspondents who will advise me on the varieties indicated above as to their fitness for main crop purposes.—ALFRED PEACOCK.

### COTTAGE GARDENING.

"COTTAGE GARDENER" has always held an honourable position among the titles of the Journal, and there has hardly been a number without some hints of value for the owners of cottage gardens. Such hints are, however, not always apparent, as a prominent position is not often assigned them, and many of my village friends are not wont to bestow more than a passing glance upon the articles in which they are to be found, probably thinking very naturally that elaborate instructions upon the culture of any particular plant or crop can only be intended for the benefit of gardeners having special facilities for doing it. Glad should I be to find that I am mistaken in so thinking, and to know that the valuable cultural hints with which the pages of the Journal abound are intelligently read and applied to practice by all readers. However this may be, there can be no doubt that notes written for a special purpose are more calculated to receive particular attention from those to whom they are addressed than others of a general character, and therefore I have no hesitation in contributing hints for those having small gardens and desire to make the most of them. In our village we have a club—not the old-fashioned benefit society, which holds its monthly meetings at the village inn, but a decidedly modern institution, which aims to care for its members in health as well as in sickness by promoting social intercourse, and placing within their reach facilities for pleasant rational amusement and self-culture. Our reading-room and library is a pleasant comfortable apartment, very attractive on a winter's evening with its bright lamps, warm fire, and large central table bountifully laden with daily, monthly, and weekly periodicals and newspapers, among which I am glad to say the *Journal of Horticulture* is to be seen.

It was a pleasant surprise to me to find the Journal upon the table without any hint as to its purchase from myself, and the sight of it gave rise to the thought that, by its aid in such a place, much might be done to brighten the village gardens and to render them more productive of good fruit and vegetables. Such gardens are generally from a quarter to half an acre in extent, and afford sufficient space for much more than a Cabbage bed and Potato plot. A tolerably good succession of vegetables might be had as well as many a little luxury of fruit in its season if every foot of space were turned to best account. Hard work bestowed upon a man's own holding undoubtedly brings a very sweet reward, for nothing in life is half so good as what is gained by our own exertion in our own home and its surroundings. Old Will Hobbs once said to me, "There's naw'n got by hard work o'ny aching bones." But I felt certain he did not mean it, for he has a very snug cottage and a neat garden all his own, and all the result of downright hard work; and the garden, too, is not without its special attractions. I do not mean the pigstye that stands well away from the cottage, and which is never long without an occupant; but that Rose bush that has its hundreds of blooms every summer, and is so beautiful that I have more than once gone in to see it and discuss its charms with dame Hobbs; and the Lilac, which I was able to tell her surpassed every one of ours at The Hall last season. Then, too, there is a bush of Rosemary, another of Southernwood, and, greatest treasure of all, a large tuft of double blue Violets.

To this very limited list of sweet things I propose to make some additions in subsequent notes; but no new plants will ever be regarded as these are, for they were there when the sons and daughters, now out in the world, played around them, and they

are as dear to them as the old home itself, of which they are regarded as part and parcel.—EDWARD LUCKHURST.

#### GARDENIA CITRIODORA.

A NATIVE of Natal, this deliciously fragrant white-flowering evergreen shrub does not require a high temperature, thriving excellently in an intermediate temperature or cool stove. The foliage is a bright deep green, the leaves longer and broader than *G. florida*. The fine Jasmine-like flowers are produced from the

axils of the leaves of the last year's growth in a branched peduncle of several flowers, white, and having a delightful Orange-blossom-like fragrance, hence their value when mounted for bouquets. A plant in flower is sure to awaken interest and attract attention by its agreeable perfume. Flowering naturally at the dull season, usually in December or January, it is a welcome addition to our list.

It is very easy of culture. Not being a cross-rooting plant it must not be overpotted and when at rest overwatered, or the flower buds will drop; indeed, at no time must a sodden condition of the soil

Fig. 8.—GARDENIA CITRIODORA.

exist, or the plants will suffer. Any pruning—*i.e.*, shortening of irregular growths, should be performed after flowering; and when the plants have started fresh growth repot, merely removing the old soil, disturbing the roots as little as possible, draining efficiently, and employing a compost of turfy loam with a little leaf soil or thoroughly decayed manure. Syringe overhead daily during growth, watering copiously, affording a light position to solidify the growth. Strong shoots often spring from the base. Stop them when a few inches high, or they will so appropriate the sap as to cause the old growths to die. The other growths must not be stopped as the stronger they are the more profuse

and finer are the flowers. The accompanying spray, of which I have grown many such, indicates the attractive character of this *Gardenia*.—G. ABBEY.

#### DEATH OF MR. JOHN SPENCER.

It is with unfeigned regret that we have to announce the death of a distinguished horticulturist, an accomplished man, and a public benefactor, in the person of Mr. John Spencer of Buck Hill House, Calne. Mr. Spencer was best known in the horticultural world as "Mr. Spencer of Bowood," for it was there as

gardener to the Marquis of Lansdowne that he made his mark in the pursuit which he so much adorned.

It is near upon fifty years since Mr. Spencer went to Bowood as gardener to the grandfather of the present Marquis, and up to the year 1860, when he resigned this appointment to take the more responsible position of steward of the Bowood estates, the services he rendered to horticulture are recorded in almost every horticultural periodical and work of the period, and as a recognition of his merits in this respect he was early elected a corresponding member of the Horticultural Society of London, to the *Journal* of which he contributed several useful papers, and of the Council of which he was for several years a member, when it extended its work to South Kensington. In 1862 he became associated with his friend, Dr. Robert Hogg, in the proprietorship of "The Florist," which had been previously conducted by Mr. Edward Beck and Mr. Charles Turner; and now it was issued in a new series under the designation of "The Florist and Pomologist," on account of the greater prominence given to fruit in the new series. As his duties in connection with the Bowood estates and his public engagements required his attention, Mr. Spencer was obliged after a time to relinquish his literary connection with the gardening press, though from time to time he continued an occasional contributor to the pages of this *Journal*.

In 1854, in conjunction with Dr. Hogg, Mr. Spencer was instrumental in forming the British Pomological Society, and along with him was for several years joint honorary secretary. There was no important horticultural movement at that time with which Mr. Spencer was not associated; and there was none, the success of which was not nourished by his presence and influence. Like his old friend, Sir Joseph Paxton, he was a great power in horticulture, and not in horticulture alone, but in every social movement which required sound judgment and deliberate persistent action with which he was invited to co-operate.

It was not, however, in horticulture alone that Mr. Spencer was proficient; other branches of science and of general knowledge had equally their attractions for him, and especially in geology he acquired a wide reputation. On this subject he was a frequent lecturer at the provincial institutes of the district, and there was perhaps no one who could speak with higher authority and had greater experience of the geology of the Oxford oolite and the Bagshot Sand, both of which were abundant in the district, than Mr. Spencer. No greater treat could be enjoyed than to have the privilege of a drive through the picturesque country in which he lived, and to listen to his pleasant talk and exposition of the formations over which we were travelling and by which we were surrounded. These were occasions which will always remain fresh and green in the memory of the writer.

It is impossible in a short notice like the present, which has been hurriedly prepared, to give anything like a perfect sketch of the career of this estimable man, and we will therefore merely mention some of the public offices he held, and which will show the high position he held in the esteem and confidence of the county and district in which he resided. Up to the time of his death, which took place on the morning of the 10th inst. a little after ten o'clock, he was Vice-Chairman for a great many years of the Calne Union, and Chairman of the Assessment Committee. He was also for some years one of the Directors of the North Wilts Bank, and subsequently, on the amalgamation of that with the Hampshire Bank, then styled the Hampshire and North Wilts Banking Company. This subsequently became the Capital and Counties Bank, and he retained his seat on that board as a Director to the end of last year, when he resigned consequent on his failing health. He was one of the oldest Free-masons in the province of Wilts, in which he had held every office, and was a Past Provincial Grand Senior Warden.

Mr. Spencer was born at Langley in Derbyshire, on the 27th of June, and was consequently in the seventy-second year of his age.

#### DEATH OF MR. WM. GORRIE OF EDINBURGH.

WE are sorry to have to announce the death of Mr. William Gorrie, President of the Botanical Society of Edinburgh. On the evening of Thursday last, the 6th inst., Mr. Gorrie was on his way home in the train from Edinburgh to Newhaven, and expired in the railway carriage of heart disease. Mr. Gorrie has been a prominent figure in Scottish horticulture for nearly fifty years. Trained by his father, the late Mr. Archibald Gorrie of Annat in Perthshire, he early exhibited those qualities which led him to take an important place in the world in after life. When yet a young man he entered the establishment of Messrs. Peter Lawson & Son of Edinburgh at the time when the late Mr. Charles Lawson originated the Agricultural Museum, which afterwards became the property of the Highland and Agricultural Society

of Scotland, and the care of the museum was entrusted to Mr. Gorrie, who for several years continued to be its curator. During this time he was also occupied in the preparation of the *Agriculturists' Manual*, published by Messrs. Lawson, and which was the joint production of Mr. Gorrie and Mr. Charles Lawson, the former getting the matter together, conducting the experiments in the experimental nursery at Meadowbank, and the latter giving a general supervision and advising on the technical parts of the work. For some years afterwards he acted as steward to the Earl of Stair at Oxenford Castle, where his attention was much occupied with the culture and crossing of Rhododendrons, and subsequently he returned to Edinburgh to take charge of the extensive nurseries of Messrs. Lawson. Of late years Mr. Gorrie has retired to comparatively private life, though still active in the pursuit of his love of plants and botanical studies. His little garden at Raitt Lodge, Trinity, was a Noah's ark of horticulture, where he delighted to spend, no matter how long, with friends who would enter into and appreciate his tastes, and his spare time was occupied in practising landscape gardening and garden designs.

#### HARDY FRUIT GARDEN.

THE favourable change in the weather will admit of pruning being completed. Apples and Pears grown as pyramids, bushes, or cordons should have attention, so that the borders can be cleaned and mulched with rich material. In pruning it should be remembered that some Apples and Pears produce their finest blossoms and fruit on the terminal points of the last year's growths; therefore pruning-in too closely should be avoided, except in the case of very gross shoots. If summer pruning, and, with extremely vigorous trees, root-pruning, have been attended to, there should be very little use for the knife at this season, though it may be advantageously employed to thin out wood or spurs where too thickly placed. For weakly trees with an overcrop of bloom buds it is advisable to remove some of the buds where too closely set to give additional strength to those retained, an overcrop of blossom taxing the energies of the trees so severely as to prevent the fruit setting and swelling freely. Plums as bushes make a quantity of spray, soon becoming crowded with spurs, and unless they are thinned some are likely to die. Remove dead spurs and all unnecessary growths. The pruning, dressing, nailing, or tying of the above-named trees and Cherries should be concluded as soon as possible. Apricots are best pruned early, as the wounds have more time to heal, and are consequently less liable to gum than when the sap is active. Beyond cutting out the old weak bare wood, shortening any long spurs, thinning where too crowded, and keeping the growths close to the wall, the knife should be used as little as is necessary to ensure the symmetry of the trees.

#### FRUIT HOUSES.

*Cherry House.*—If the house was closed early last month a little fire heat will now be needed to keep the temperature at 40° at night and 45° to 50° in the day, allowing an advance of 5° to 10° under the influence of sun heat. It is, however, a great mistake to proceed too hastily in the early stages of forcing fruit trees, particularly with the Cherry; therefore commence ventilating the house at 0°, and when the weather is mild and sunny admit air abundantly. Attend regularly to watering trees in pots, syringing them occasionally, and damping as required to promote growth. If black aphides are present fumigate repeatedly, so as to have the trees clean before the blossoms expand.

*Cucumbers.*—Plants in bearing will require to be examined at least twice a week, removing all weakly and exhausted growths, and reserving as many of the young bearing shoots as will maintain a balance between the roots and foliage, retaining, however, no more than can have full exposure to light. Stop the shoots one or two joints beyond the fruit, keeping strong plants more closely stopped than those that are weakly. If mildew appear promptly dust the foliage with flowers of sulphur, also applying it to the hot-water

pipes. Damp the floors and other surfaces at about 8 A.M. and 2 P.M., repeating it if sharp firing be necessitated in the early part of the evening.

*Figs.*—See that the fermenting materials in the bed are replenished from time to time as necessary to maintain the heat of the material about the pots steady at 70° to 75°. The forward trees being now in active growth will require abundant supplies of weak liquid manure of the same temperature as the bed—viz., 75°, and should have a top-dressing on the surface of the soil of well-decayed manure. The night temperature may range from 55° to 50°, and 60° to 65° in the daytime artificially, commencing ventilating from 65°, increasing it with the rising temperature to 75°, keeping it between that and 80°, and close the house at 65° to 70°. Trees planted out intended to afford ripe fruit about the end of May must now be started, keeping the temperature at 50° at night, 55° by day from fire heat, and from 60° to 65° from sun heat, allowing a free circulation of air above 65°.

*Strawberries in Pots.*—Another batch of plants should be introduced to a Peach house or vinery where no special structure is at command for the forcing of the fruit to succeed those which were introduced in December, which will now be well advanced for flowering, and it is important that aphides should be subdued before the flowers expand. Until flowering a temperature of 50° to 55° is most suitable, and with an advance of 5° to 10° from sun heat, accompanied with a free circulation of air, which is essential to the vigour of the trusses and blooms. It is also essential that the house have free ventilation whilst the plants are in flower with the temperature above indicated, and the blossoms kept dry, assisting fertilisation by liberating the pollen with a feather or camel's-hair brush. When the fruit is swelling the temperature should be 60° to 65° at night and 70° to 75° by day, with 5° to 10° more from sun heat, maintaining a moist atmosphere, and feeding with liquid manure, continuing this treatment until the fruits change colour, when a drier atmosphere and less supplies of water at the roots will be necessary to ensure good flavour.

#### FLOWER GARDEN.

As there is little of an attractive character in this department it is of the greatest importance that the walks and grass be kept in the best possible condition by frequent sweeping and rolling, having the beds and borders neat. Lawns or grass verges that have an uneven surface should be attended to at once, as nothing is so offensive to the eye as an uneven lawn. Any alteration involving the relaying of turf should be proceeded with in favourable weather. The surface of lawns that are mossy should be well raked and top-dressed next month with a mixture of lime, wood ashes, and soot, in about equal parts, applied at the rate of a peck per rod. Shrubbery and herbaceous borders should now be dug over as deeply as the roots and plants will allow, affording a top-dressing of decomposed refuse or old potting soil. The stronger-growing herbaceous plants, such as Phloxes, will be benefited by a good dressing of manure, and Hemerocallis, Irises, &c., outgrowing the space allotted to them may be re-arranged or reduced. Where it is intended to grow *Ricinus*, *Wigandias*, *Solanums*, and *Cannas* a good dressing of manure must be given, and the ground trenched; also for *Dahlias*, *Hollyhocks*, and other plants that require a deep rich soil.

#### PLANT HOUSES.

*Orchids.*—*Dendrobiums* that are showing flower should receive a moderate supply of water at their roots, and will require an increase of heat to enable the flowers to grow, along with all the light possible. Care must be taken not to excite the general stock of *Dendrobiums*, nevertheless the plants must not be allowed to shrivel; the same remarks applying to *Cattleyas* and the majority of the Mexican *Orchids*. *Cypripediums* will require a plentiful supply of water, alternating occasionally with a little weak liquid manure. *Oncidium*s and *Odontoglossum*s will be coming into flower, and must be well supplied with water, otherwise the pseudobulbs will shrivel. *Odontoglossum*s that are growing rapidly should have a good supply of water at the roots. Keep a sharp look-out for insects, especially aphides, and promptly destroy them by fumigation. The temperature, from which no injury will result by a deviation of a few degrees, should be, for the East India house, 60° at night and 65° to 70° by day; Mexican house, 55° by night and 60° by day; cool or *Odontoglossum* house, 45° to 48° at night and 50° to 55° by

day. The necessary materials for potting *Orchids* may now be procured. A good supply of sphagnum is of first importance, and should have all the rubbish picked out of it, especially woody matter, as it encourages fungus. Peat will also be necessary, and crocks and pots should be washed clean. Material for baskets should also be procured, maple or oak and teak being most suitable.

## THE BEE-KEEPER.

### SHOULD BEES BE BRANDY-BIBBERS?

YOUR valued correspondent "B. & W.," in giving in a recent issue some well-timed "hints for safe wintering," recommends that the syrup used in feeding should be "fortified with a little gin or other spirit." I so generally agree with the writer that he will, I am convinced, regard me as only working with him for the common good if I explain my views upon this matter, which are certainly in this case most pronounced and the exact opposite of his own. The question involved is one to which I have given some little attention, and my settled conviction is that no greater error could be committed than that of giving to bees alcohol in any form. But no man has a right to an opinion until he has earned it by studying the grounds upon which it should be based, so I ask the indulgence of "B. & W." while I give the reasons for my position.

Different kinds of sugar, such as sucrose, glucose, and lactose, agree in containing carbon, hydrogen, and oxygen, the latter two in the proportions in which they form water. This sugar becomes the heat-giver to the bee in the following manner:—Air containing oxygen is taken in by the bees through the spiracles (the breathing openings) in the sides, of which there are fourteen in number, and this oxygen is by degrees united with the carbon of the sugar, which is being carried about in solution in the fluids of the insect. The carbon thus becomes a part of a gaseous product—carbon dioxide, which is thrown out from the breathing tubes (tracheæ) at every contraction of the abdomen. The union of oxygen and carbon is always attended with a great evolution of heat, and is, indeed, the sole cause of the fervour of a charcoal fire, and mainly gives intensity to one of coal. Heat, then, is developed within the bee's body as this chemical union progresses, and during the winter each insect plays its part in keeping up the temperature of the cluster. It must be added to save misconception, that in certain circumstances the organised tissue of the insect may itself unite with oxygen and contribute to heat formation, but our argument will be made the clearer if this point be left out of view.

We have now to consider the physiological effects of alcohol to ascertain whether the bee would be likely to be assisted by it in keeping out the cold, and here we must argue from its well-ascertained action upon men and some of the higher animals; but in this we shall be justified, since morphia, strychnia, aconite, and some other drugs are well known to microscopists to influence creatures even so low in the scale as infusoria and rotifera after the same manner as they affect those with the most complex organisation. Numberless experiments upon men, dogs, and Pigeons have clearly shown that alcohol *hinders* the union of oxygen with carbon in the vital fluids, and in consequence a smaller amount of heat is produced during its presence in the blood, while it follows that less carbon dioxide is thrown out. Applying this to the bee, it would follow as a matter of course that it would be far less able to withstand the rigours of winter with it than without it. Those who know anything of the history of our arctic expeditions will recognise the complete corroboration which these give of the truth of this position. That alcohol produces a feeling of flush is well known, but the cause is the partial paralysis of the pneumo-gastric nerve, the duty of which is to hold in check the minute blood vessels. The check removed, the blood vessels stretch out under the pressure of the contained blood, and a general surface blush is the result; but this no more produces warmth than would turning the hot inside of a manure heap to the surface warm it. Indeed it is an act of cooling, in which heat that before was deeply seated is made to display itself, but is at the same time lost by dissipation in the surrounding air. Those who care to look to the *Lancet* for August 25th, 1866, will find details of some remarkable experiments tried in University College Hospital, putting this matter in the clearest light, and showing that alcohol immediately after the first flush is a most persistent and powerful depresser of temperature. But since the structure of the circulation of insects is very unlike our own, it is

chiefly important for us here to note that its action is due to its lowering of nerve energy, than which nothing would be more likely to unfit bees for battling with the adverse conditions of a protracted winter. That alcohol may give a flash as it were none will deny; but even this it does not do because it gives strength, but because it renders a further paying-out of our resources possible; but as they are paid out we are left poorer, weaker, than before, hence the excitement brings exhaustion, and the higher the one the deeper the other. Alcohol is an irritant, and therefore a waster of vital energy, and so the very reverse of that needed by wintering bees, every power of which should by all means be husbanded in order that returning spring may find them with a large balance of energy still standing to their account.

Three powerful reasons, amongst several others unmentioned, are now before us, each one by itself sufficient to condemn alcohol as a part of bee food. We find it hinders oxidation and prevents heat being developed. It lowers nerve tone, and so in the end weakens. It irritates and therefore exhausts, while, so far as I have been able to discover, it does not bring us for these evils one countervailing advantage.

Good indeed would it be for many if the old unscientific delusion that alcohol keeps out the cold were altogether dispelled; but I write because I am deeply convinced that it will be good for our bees when every bee-keeper knows that protection keeps in the heat, and that good honest sugar is the right thing to produce it.—FRANK CHESHIRE, *Avenue Road, Acton.*

### CONGRESS OF GERMAN AND AUSTRIAN BEE-KEEPERS.

(Continued from page 15.)

As stated last week, the next question discussed was, "What are the essentials to be observed in order to winter colonies of German, Italian, and Carniolian bees well?" After some introductory remarks, which contained many valuable hints respecting wintering bees, Mr. Schlösser said that when Italian colonies had a population too small for wintering them it was advisable to strengthen them early in autumn by giving some brood comb or bees from other hives. The Italians should not be allowed to indulge their bad habits of tearing out their brood in autumn when there is nothing more to be gathered. Italian bees, he continued, were in the habit of arranging their brood in regular succession, and if not induced by feeding to make useless excursions they were always in a more advanced state than German colonies in spring.

Italian and German colonies with about 4 lbs. of honey at the end of March would raise proportionately less brood than if they had 12 lbs. of honey left; but Carniolian bees, as well as their hybrid descendants, often commence breeding early in the spring without any regard to the quantity of honey there may be in their hive. Gübler preferred to treat all races of bees alike. In his opinion the chief thing is to winter bees in a cool situation and in thick-walled hives with isolating layers. He wished the hives to be arranged in such a manner as to admit cool air to the bees. Another gentleman believed that nine-tenths of the bees perish through bad construction of hives. Mr. P. Schachinger of Vienna advocated wintering bees in a place which keeps out the frost, but from which heat of course should also be excluded. Mr. Klausmeyer described a different arrangement of the flight hole.

A "Few Observations on the Physiology of the Bee," by Dr. Dönhof—who was unable to finish his subject on account of the lateness of the hour—is a most valuable paper, and is published at length in the "Bienenzeitung." To a citizen of Cologne, however, it was reserved to carry off the local honours of the discussion.

Mr. Schüller introducing the question "What is the cause of the decline of bee-keeping in the city and district of Cologne which at one time was in such a flourishing condition, and what should be done to advance bee-keeping there?" expressed himself as follows:—"To make bee-keeping a success four things are necessary—1, The Cultivation of melliferous plants; 2, a sufficient number of hives; 3, Intelligence in the management of bees; 4, Favourable weather. As regards the last point, it might not be out of place here to quote the words of the late Baron von Berlepsch, 'When the sources of honey are flowing even the hedge poles furnish a supply.' The decline of bee-keeping in Cologne dated from the day when the first sugar factory was established there, which was immediately followed by the following strange police regulations:—

"I. It shall not be permitted to keep more than five stocks of bees to one house within the city of Cologne in such a way as to make it possible for the bees to get to other people's property. (The reading was interrupted by loud laughter and ironical cheering.

"II. Any person who keeps more than five hives of bees shall be liable to a fine of one to ten thalers (3s. to 30s.) for each hive above this number, or shall be liable to imprisonment if unable to pay a fine.

"III. This regulation shall come into force on the 1st March, 1855.

"Cologne, 5th December, 1854.

"Signed by the Superintendent of Police,  
"GEIGER."

"Gentlemen," continued Mr. Schüller, "I am sure there cannot remain the slightest doubt in your minds that this police regulation was drawn up without the assistance of any Cologne bee-keeper (Renewed applause). When this regulation came into force the fate of bee-keeping in Cologne was sealed. We have been endeavouring for years to get this law repealed, but not much progress has been made. From my point of view as a bee-keeper I maintain that bee-keepers existed before the sugar factories were built. Bees can easily be kept away by wire netting. It is incomprehensible to me how the tax-paying citizens of Cologne could have been made to put up with such regulation. Bee-keepers of Germany and Austria, let us get this police regulation withdrawn and in its place have legal protection to bee-keeping!"

Many other gentlemen spoke strongly to the same effect.

Pastor Weygandt read an excellent paper on "The Transfer of Larvæ from one Cell into another." The speaker admitted that, strictly speaking, this procedure was of no great practical value at present, but he thought it might afford very many advantages hereafter. For example, he said a bee-keeper may have a strong colony of German bees, of which he does not want any offspring; he may at the same time be possessed of a small colony of Cyprian, Carniolian, or Italian bees with an original queen. It might thus occur to him how desirable it would be to obtain as many queens of the new race as useful queens of the German colony. Pastor Weygandt proceeds by cutting open with a pair of scissors a royal cell in a comb of a German colony, bending the edges back, taking hold of the royal larva in the cell by means of a pair of tweezers, and removing it. He then places the worker larva of the race from which he wishes to rear queens upon a small camel's-hair brush previously moistened, and transfers it to the empty royal cell, embedding it in the royal jelly, and after this no further manipulation is requisite. The workers in almost every case seal the cell, and the worker larva becomes developed into a queen. The metamorphosis is in most instances distinctly recognisable on the following day. In reply to a question as to the age of the larva to be employed in such manipulation, Pastor Weygandt said it did not make much difference. He had by such transfer succeeded in changing worker larvæ which were on the point of passing into the pupa state into royal larvæ, and had occasionally obtained very vigorous and even the most beautiful queens. The practical advantage of such a transposition consists in our keeping a German colony a number of queens of the race which it is decided to increase. Pastor Weygandt's most interesting speech was loudly applauded. It was followed by a discussion on the composition of chyle.—ALFRED NEIGHBOUR.

(To be continued.)

The Title-page and Index of the last half-yearly volume of this Journal will be published next week.

**Garden Hose (Amateur).**—Vulcanised indiarubber hose an inch in diameter will be suitable for your purpose. We are unable to state the cost of hose and fittings; this information is best obtained from an ironmonger or dealers in garden requisites.

**Dalechampia Roeziana rosea (Alpha).**—You will find the cultural notes to which you refer as having been written by Mr. Wills, in No. 365 of the *Journal of Horticulture*, page 1, vol. xiv. You are quite right in your assumption that the author of them is the "great floral decorator of Warwick House, Regent Street, London."

**Garden Walls (Deodar).**—We are much obliged to you for your suggestion. Had we been aware of your possession of the back numbers we should have given the information in a different form. You will find the details of building walls illustrated on pages 50-51 of vol. xiv, new series; you will also find the subject treated on rather fully in vol. x. on pages 366, 430, and 431.

**Growing Fruit (J. B. B.).**—With ordinarily fertile soil there is no doubt whatever you may succeed in growing all the most useful hardy fruits if you follow the instructions that are published from time to time in this Journal. If you require specific information at any time to aid you in carrying out your project, we will readily supply it if you will state your wants fully and clearly.

**Peas for Succession (Reader).**—You will find a selection of useful varieties in reply to a correspondent on page 16 last week. If you add to the varieties there named those mentioned in your letter you will have the number you require, and which, sown at proper intervals and well cultivated, will afford excellent produce as early and as late as the weather permits.

**Forming Oval Beds (P. P.).**—If you refer to the issue of the Journal of June 3rd, 1880, you find two diagrams that will give you the information you require. If you do not possess the number it can be had from this office post free for 3½d. The name of your plant is *Ficus repens*.

**Planting Strawberries (J. C.).**—We are unable to inform you the cost per acre of planting Strawberry runners, as so much depends on the nature of the soil, the cost of the runners—some varieties being dearer than others—and the skill of the men employed. Assuming that the runners are small, early spring, just as signs of fresh growth are apparent, would be the safest time to plant. In the absence of farmyard manure 5 cwt. of guano and 2 cwt. of salt

per acre would answer on most fairly well-conditioned land; but if the land is naturally moist the salt should be withheld. Mr. Raitt's articles on Strawberry farming will probably afford you useful information.

**Fruiting Vines in Pots (J. Dixon).**—Your Vines being in 12 and 13-inch pots you may fruit them in these, or you may pot them into 18-inch pots, providing good drainage and not disturbing the roots. If you keep them in the 12-inch pots be content with putting the drainage right, relying on top-dressings of manure and applications of liquid manure at the same time. The Vines would carry a heavier crop if the pots were placed on shallow tubs containing soil, into which the roots could run after passing through the holes in the bottoms of the pots, which they would do freely. We shall shortly publish some notes on this subject.

**Peas and Broccoli (A Reader).**—Moderate-priced varieties of Peas of good quality growing 3 to 4 feet high are William the First, Laxton's Alpha, G. F. Wilson, James' Prolific, Princess Royal, Maclean's Best of All, Veitch's Perfection, and Omega. The heights of Peas vary with soils and seasons. Ne Plus Ultra grows taller than you require, nevertheless you ought to include it, as it is valuable for affording a late supply. Useful Broccoli for succession are Snow's Winter White, Cooling's Matchless, Leamington, Carter's Summer, and Suttons' Queen.

**Insects (W. Martin).**—The insects from having been wrapped in dry wadding were so dry and withered, mere husks only remaining, that it is impossible to identify them. If we can receive some in a fresh sound state, and you will inform us what plants they infest, we will endeavour to name them for you.

**Propagating Pyrus (Cydonia) japonica (A. H.).**—The best mode is to layer the shoots in September, pegging them into the soil at a sufficient depth to ensure their being constantly moist, and there let them remain for twelve months before they are severed from the parent tree. They are also increased from seeds and suckers. The Cabbage Broccoli is not, that we are aware of, yet in commerce.

**Carnations in Winter (Inquirer).**—La Belle and Guelder Rose are very useful white varieties, A. Alegatière scarlet, and Scarlet Defiance, with Rose Perfection are also good. We have tried the plan of growing them in the open ground during the summer, lifting and potting the plants in the autumn, but it is not so satisfactory as growing the plants well in pots plunged in ashes. By the former plan many of the plants receive a severe check, which seriously limits their period of flowering, which does not occur when the plants are grown in pots throughout.

**Layering Roses (Idem).**—If you layer or peg down the strong shoots of the Hybrid Perpetual Roses you will obtain far more flowers than if you prune them severely. Roots will also be emitted in due time from the layered portions if they are covered with soil deep enough and always kept moist.

**Camellia Flowers not Expanding (Florist).**—If you had sent us a portion of the growth as well as the decayed flower buds we should have been better able to have formed an opinion on the case. You say the "tree is perfectly healthy, with fine dark foliage, and is a very free bloomer, but not 1 per cent. of the flowers expand." Occasionally when a Camellia produces its growth in the full sun that growth becomes prematurely matured, and a great number of flower buds set. In that case, if a number of the buds are not thinned out, the flowers rarely expand, but most of them decay in the centre and fall off. Assuming that your plant has been properly supplied with water, and the temperature is suitable, we think you have left too many buds on the shoots, and as these could not have the support requisite for perfecting the flowers they have failed to expand. Some Camellias, however, never open their flowers so freely as others, and yours may possibly be one of the "stubborn" varieties. If this is not the case we think we have indicated the cause of failure.

**Vegetables for Exhibition (A. J. J.).**—From July 10th to August 10th the following will be suitable:—Red Round Potatoes.—Triumph and Beauty of Kent. White Round Potatoes.—Porter's Excelsior and White Emperor. White Kidney Potatoes.—Veitch's Improved Ashleaf and Woodstock Kidney. Peas.—Carter's Stratagem, John Bull, and Ne Plus Ultra. Broad Beans.—Seville Longpod, Carter's Leviathan, and Hardy's Pedigree Windsor. Runner Beans.—Champion Scarlet and Giant White. Dwarf Kidney Beans.—Canadian Wonder and Negro Longpod. Turnips.—Sutton's Snowball and Carter's Jersey Lily. Parsley.—Veitch's Curled and Carter's Fern-Leaved. Lettuce.—Alexandra Cos and Suttons' Superb White Cos. Parsnips.—The Student. Carrots.—Nantes Horn. Radish.—Red and White Turnip. It is unwise to rely upon one variety in each instance, or upon one particular sowing, as so much depends upon the nature of the soil and the weather experienced. Grow good breadths of a few standard varieties in preference to small patches of many sorts. Telephone and Telegraph Peas, which you have, are when in good condition unsurpassed for exhibition purposes; but on your light soil very probably they would be past their best towards the end of the stated time, and would then be excelled by Ne Plus Ultra. Stratagem is a dwarf and somewhat later form of Telephone. John Bull is scarcely so large in pod, but opens well, and this tells in its favour. A good dish of Ne Plus Ultra is not easily surpassed.

**Propagating Hardy Ferns from Spores (D. D.).**—Choose a pot which a bellglass will just fit within the rim, place a large crock over the hole, half fill the pot with smaller pieces, and on them place half an inch of moss; then fill the pot to the rim with the following mixture—viz., sandstone broken in all sizes from that of a grain to a hazel nut, sandy fibrous peat, and yellow fibrous loam, of each equal parts, adding to the whole one-sixth of silver sand. Put over the surface a very small quantity of sifted soil, and make it firm by pressing it with the hand. Put on the bellglass, and if it fit closely on the soil it is all right. Remove it, and stand the pot in a pan in a rather shady but not dark part of the greenhouse, for what is wanted is a diffused, though not a strong light. Give a good watering all over the surface through a fine-rosed watering-pot, filling the pan with water. Now take the frond with the spore cases open, and, holding it over the pot, rub it with the hand on the under side, and a kind of brown or yellow dust will fall on the soil. You may scrape the spore cases from the back of the fronds, but if the dust fall so as to make the soil brown or yellow it is enough. Press the surface gently with the hand and put on the bellglass, taking care that it touch the soil all round. Keep the pan or saucer full of water, and give none on the surface except it become dry, which it never ought to do, nor will it if sufficiently shaded and the saucer be kept full of water. When the surface becomes green tilt the bellglass a little on one side at night, and as the soil becomes greener tilt it higher, giving a gentle watering now and then to keep the surface from becoming dry. When the plants have made two or three fronds gradually remove the bellglass, and pot off the Ferns when they can be handled safely. The pots may be placed in a pit or a shaded position in a greenhouse.

**Cactus not Flowering (C. C., Donegal).**—You have treated your plants

too generously. In all probability they do not need repotting annually, and if they do the spring, not the autumn, is the best time for the work. The soil you employ is also too light. Two-thirds of turfy loam and one-third of leaf soil with a liberal admixture of crushed bricks, a little mortar rubbish and charcoal, form a suitable compost, the soil to be pressed very firmly round the roots and the plants not overpotted. In such soil the leaves will have more substance than when the plants are grown principally in leaf soil. From October to March, if the plants are kept cool, they will scarcely need any water, a soaking once every ten days or a fortnight being ample. When growth commences the supply of water must be increased, and throughout May, June, and July when growth is rapid it must be liberal. During the last-named month place the plants outdoors in the driest and hottest position at command, and when the growth is made gradually withhold water, and eventually give only just sufficient to prevent the stems shrivelling, they will then assume a bronzy hue and flower buds will form. Remove the plants to their winter quarters before the occurrence of autumn rains, just keeping the leaves fresh during the winter, and you may expect flowers in the spring.

**Pruning Roses in Pots (Idem).**—Remove the soft unripe portions, and proceed as described on page 10 last week; probably a third in length of the shoots will have to be cut off, as by your description the wood appears to be in an unripe state. Bone dust sprinkled on the surface of the soil is an excellent manure for Roses. If the soil is of such a character to adhere to the roots well the plant will probably sustain little check by being taken up and potted, but if it is light and falls away from the roots the plant will not expand its flowers after its removal.

**Names of Plants (B.).**—The larger form is a species of Hymenophyllum, probably H. tunbridgensis, and the smaller specimen resembles a Jungermannia, but both were insufficient for certain identification. (T.).—Asplenium lucidum.

**Scottish Bee-keepers (A Bee-keeper).**—If you will inform us in what way you conceive the information which you ask us to publish would be of general benefit the subject shall have our consideration.

#### COVENT GARDEN MARKET.—JANUARY 12.

#### POULTRY AND PIGEON CHRONICLE.

#### AGRICULTURAL IMPLEMENTS AND MACHINERY.

UNDER this heading a very extensive assortment of implements seem to claim our notice; we propose, however, only to occasionally refer to them, in order that other subjects more appropriate to the time of year may not be excluded. The use of new and improved implements is not only important as labour-saving, but also as a saving of time and money, all of which are of the greatest consequence to the home farmer, particularly as manual labour is not available as it was formerly, and in many important farm operations the labour of women and boys is missed, for in some districts female workers cannot be obtained.

We will first notice a very valuable machine in practical field labour, "Koldmoss Weed Eradicator," or improved weeding and seed-gathering machine, "Jurgenson's Patent," and sold by

nearly all local agents in the kingdom. This implement is extremely useful in the removal of weeds which may be growing amongst corn when it is in the last stage of blade just previous to the ear shooting-up in the stalk, and upon many farms where Charlock and wild Mustard abound the corn may have been drilled wide enough to horse and hand-hoe, yet such weeds as named will be found to a more or less extent to be left growing in the rows of corn, whether of Wheat, Barley, or Oats. In such cases and when the ground is soft the weeds are drawn up by the root, in other cases their heads are pulled off, in either way destroying the weeds or preventing their reproduction. It must be used at the time when the weeds have made considerable progress and the corn is yet in the blade, so as to freely admit the passage of the revolving combs either over or through it. The combs are lines of iron claws fitted along the drum of the machine, and revolving with it by a process of mechanism, and so adjustable that they can be lowered or elevated to suit the condition of the crops upon which they are required to operate. When so disposed or regulated they pass harmlessly through or over the young corn, and at the same time pull up the weeds, leaving them behind to die. We quote the result of a trial of the machine by a Mr. T. Casey, agent to Messrs. Ord & Maddison, who says, "We started the weeder about two o'clock. The day being wet was unfavourable. The field was covered with Charlock, no blade of corn could be seen. There were about eighty farmers present, and I believe there would have been as many more if the weather had been fine. Never did I see people more astonished, as the weeder made beautiful green lanes as it went up and down the field. Loud were the praises of the bystanders. A more successful trial could not have taken place." Since this trial large numbers of this implement have been sold, and the testimony of practical farmers who use it is favourable. These machines are drawn by one horse and are light of draught, as they only cover a space about 6 feet 3 inches in width. This weeding machine is at the same time the most useful and the best known implement for gathering White Clover and other seed-heads, and consists of a hollow drum resting upon two ordinary wheels, and so adapted as to be raised or lowered as required. In and out of the drum work several rows of combs, which catch the Clover heads, strip them off the plant, and let them fall into a bag attached to the drum. It is necessary to keep the parts of the machine well oiled; in particular the combs have to be kept clean and bright if expected to do their work well. A machine of the usual width strips during twelve hours' work the heads of the Clover growing upon  $11\frac{1}{2}$  acres of land. In conclusion, we recommend it to the home farmer as not only the best but the only way open to him to destroy the weeds in his corn crops in the absence of the hand labour which was once so usefully and generally employed in destroying the weeds of the farm. How far the implement can be used for the same purpose in other crops further experiments may in the future inform us.

We will next refer to Gibbs' drying machines, which are now of varying capacity, and which the succession of wet seasons has tended to bring into more prominent notice. Farmers may grow abundant crops of corn and hay, but if these are to be spoilt or seriously injured by wet weather how is it possible they can contend against, or compete with, the products of superior climates, where the weather can generally be depended upon at given times of the year as favourable for the harvesting of their growth of corn and hay? We have no notes by us or any calculation as to the proportion of seasons in which the agricultural products of the kingdom can be safely harvested in the open fields. In the absence of any such calculation, however, we know that in nearly every season either the early or late harvest periods are unfavourable, but this is especially the case in certain north-western districts and Scotland. Take, for instance the hay and Oat crop in these districts. How seldom can the crops be secured without damage more or less! hence the necessity of the adoption of the plan of putting hay into large cocks whilst green, and the making of numerous small ricks of Oats as practised in Scotland and other late districts. Now it appears to us that there are many points to be considered when we find that Gibbs' drying machines are offered to us, because when the weather is unfavourable and we attempt to preserve our crops from injury in the open field, we are subject not only to damage of the produce but also the waste of it. Take either hay or corn for instance. We wait for fine weather, and our corn or grasses for hay become over-ripe. We also incur expenses in continual operations, such as turning our hay, although we use the best machinery for tedding as well as raking, but when we have done all we can the slightest change of the weather causes waste. The leaf of the Clover is lost, the falling out of the corn or its sprouting, also the labour of setting-up stooks in stormy weather, adds the cost of extra labour to the

losses under the head of waste. Again, in our Clovers, during rain the extra time of laying on the ground damages the next crop, sometimes seriously. If machine-dried the green grass may be taken as fast as cut to the drier without any loss either of the leaf of the grasses or its aroma, or the ultimate feeding value of the hay. Just in the same way with regard to corn, for not only is the grain preserved of the best quality, but the straw—which is now of more consequence than at any former period, is secured both bright and sweet.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will now depend very much upon the weather. If it is open and mild plough after roots for Wheat; the sowing may be done simultaneously with the ploughing. There is a prospect of a good plant of Wheat sown now if the land is rich enough to bear it, and especially if the land should plough up heavily and be succeeded by some copious rains to settle it down firmly. In case, however, the land should plough up light and loose it should be then pressed at the time of ploughing and sown after the presser instead of drilling, for the grain then falls into the presser grooves and finds a firm bottom to root in. Again, if the land is light and dries off quickly after harrowing, it may be rolled with the ring roller with advantage and so left. If the weather should prove unfit for tillage work it will be necessary to employ the horses in carting manure on to Clovers and grass land if the land should be frozen and capable of bearing the carts without leaving wheel tracks; otherwise earth may be carted to heaps, gravel may be carted on to the farm roads or near and around the farm homestead, in order to maintain not only a decent appearance of the premises but to enable all the carting work on the farm to be done by light horse labour.

*Hand Labour.*—This will vary in different districts. Spreading manure after being laid out on the Clovers will be required; also, in the enclosed farms, hedging, ditching, banking, &c., will be going on. In the chalk-hill and stonebrash farms the hedgerows will, some of them, come fit for cutting, so that the hazel may be made into hurdles and made up for other useful or saleable purposes. Trenching in the meadows previous to being laid up for cutting of the grass intended for hay should now be done. The irrigated meadows will also require the constant attention of the drowner by changing the flood waters, so that all parts of the crop may be made ready for early feeding at the earliest period, and simultaneously one part with another. The threshing and marketing of grain for sale, also Clover and other seeds, should now be done when the weather is favourable, for we consider that these ought to be considered as applicable chiefly to the winter months, in order that the labour of the farm both in men and horses may not be required for such purposes during the busy times of spring and summer; indeed, we consider that if corn is kept for future instead of present sale the labour is the principal point to be considered, and that, if threshing of corn takes place in the leisure time of winter and the sale deferred, the corn should be in granary ready for delivery at any advantageous period of the markets in reference to value.

The shepherds on various farms will now be engaged in the lambing season, for the Dorset down ewes will now be in the middle of their lambing time. The Hants and Wilts Downs will be just commencing their lambing season. We have previously called attention to the preparations and formation of the requisite lambing yards; therefore, at present the duties of the shepherd and his assistants will be fully required in the lambing fold both by night and by day, and in the height of the season the men may take turns in the night work, so essential to the saving of lambs which may be weakly or otherwise requiring attention. The ewes, both before and just after lambing, should receive Cabbages and sweet hay, and the shepherd must look well to the ewes after lambing, so that when the lamb cannot take all the milk the udder should be drawn, for there is nothing more injurious to young lambs than an accumulation of milk in the ewe's udders, causing them often to reject it or to suffer from diarrhoea from taking it; in fact, there are so many matters requiring attention by the shepherd, both to the ewes and lambs, that we cannot now enumerate only a few. If the ewes suffer from inflammation of the udder it is a very dangerous disorder. In such a case we always bleed the ewe from the neck vein and until the ewe falls from loss of blood. This will generally allay the inflammation, whilst the common practice of bleeding from the udder vein is absolutely injurious, because there is an increased flow of blood afterwards to the affected part. We have often found that with copious bleeding from the neck and the application of the sugar of lead ointment to the udder will effect a cure; if not, a second bleeding and an application of verdigris ointment will prevent mortification.

#### VARIETIES.

*BRITISH BEE-KEEPERS' ASSOCIATION.*—The next quarterly conversazione will be held on Wednesday, January 19th, at 6 P.M., at the Board Room of the National Chamber of Trade, 446, Strand (opposite Charing Cross station). Subject for discussion—"Cheap

Bar-frame Hives for Cottagers' Use." To be introduced by F. Lyon, Esq., of 94, Harleyford Road, London. The annual general meeting of the Members of the Association will be held in the above room at 446, Strand, on Wednesday, February 16th, at 4 o'clock P.M. Members who wish to bring forward any motion at this meeting are requested to communicate the same to the Honorary Secretary, Rev. Herbert R. Peel, Abbot's Hill, Hemel Hempstead, on or before Saturday, February 5th.

— THE MECHI FUND.—A preliminary meeting of the Committee of the Mechi Fund was held on Friday last at the offices of the Royal Agricultural Benevolent Institution. Among those present were the Marquis of Huntly (Chairman and Treasurer), Mr. Samuel Morley, M.P., Mr. Thomas Duckham, M.P., Mr. R. K. Causton, M.P., Mr. James Caird, C.B., Mr. Edwin Chadwick, C.B., and Mr. Bousfield Shaw, the Honorary Secretary. Letters were read from Lord Spencer and others regretting their inability to attend. On the motion of the Marquis of Huntly, seconded by Mr. R. K. Causton, M.P., it was resolved that a national Committee be appointed with the view of raising a fund to provide for the widow and family of the late Mr. J. J. Mechi, and a general Committee, consisting of the gentlemen present, with power to add to their number, was appointed for the purpose of carrying out that object. Among the subscriptions promised were—The members of the Court of Aldermen, £500; the Duke of Bedford, £100; the Earl of Leicester, £100; Mr. Samuel Morley, M.P., £100; Messrs. Garrett, Grimswood, & Whittaker, £105; Mr. John Maple, £52 10s.; Mr. H. R. Nicoll, £52 10s.; the Skinners' Company, £52 10s.; Mr. Jeremiah Colman, £52 10s.; Messrs. Causton & Sons, £52 10s.; and Mr. James Caird, C.B., £50.

— SOLUBILITY OF MANURES.—Dr. Morgen, in the Journal of the German Agricultural Experimental Stations, reports the results of numerous experiments on the time required to render the valuable constituents of certain manure materials available for the growing plant. The chief articles experimented on were bone meal and leather meal. The total valuable contents of each were in about the same proportions; but the solubility of the bone meal was found far greater than that of the leather. No acid was used. The materials were used as they would have been by the farmer if bought in the rough state. The author strongly recommends the use of bone meal. His conclusions have been verified by others, and the employment of bone superphosphates and special manures having bones for their base is rapidly extending. Leather, however, when prepared with acids, and after receiving certain other treatment, is nearly as valuable. It is employed as the base of some special fertilisers with most beneficial results.

— OLEOMARGARINE.—A London daily paper states that the manufacture of oleomargarine in Philadelphia has reached the large quantity of 100,000 lbs. per week, and is still very far below the demand. The manufacture consumes about 1,500 lbs. of genuine dairy butter per day, and nearly 30,000 lbs. of fat, and, strange to say, quite two-thirds of the product is sent to Europe; London, Liverpool, and Glasgow being the chief markets. The Dutch are large purchasers too; but from long experience in the making of "bosch," they do not buy the finished article. They purchase the oil before it is churned, and finish the oleomargarine themselves, being well aware of the profit to be made by the addition of the salt, milk, and other ingredients which enter into the finished article—the "prime fresh butter at 1s. 2d." of the London shops.

— FOOT-AND-MOUTH DISEASE.—A serious outbreak of this disease has occurred on the estate of the Duke of Northumberland at Isleworth, the whole of a splendid herd of Scotch runts, numbering between thirty and forty, being affected. His Grace has a number of valuable cows and heifers on the same estate, and every care is being taken to keep them from infection. The disease is also prevalent at Twickenham, Hampton, Hanworth, and other parts of West Middlesex; indeed it is said to be more general in this division of the county than has been known for some years. In the county of Buckingham, the whole of which the Privy Council have declared to be an infected area, it appears to be subsiding, only one fresh outbreak being reported last week—viz., at Penn, near Amersham.

— DISEASE IN SHEEP FROM EATING LUPINS.—Lupin hay is often used as fodder on the Continent. In a recent case half of a large flock of sheep fed on it died within a brief period. The hay on examination was found to be covered with a fungus. The suggestion has been made that steaming the hay would prevent the injurious effects, or, perhaps, strongly heating it during its preparation.—(*Irish Farmers' Gazette*.)

## POULTRY AND PIGEONS

### A FANCIER'S INCUBATOR.

DURING the past two seasons I have been employing hydro-incubators instead of hens for hatching my Dark Brahma chickens. The first season I had but one incubator, and put in the eggs as they were laid. Finding, however, that more successful results were attained by placing the entire batch of eggs in the machine at once, closing all the ventilators, and thus keeping a close moist atmosphere for the first eight or nine days, and ventilating freely for the remainder of the twenty-one days, I last year worked two incubators. No. 1 was unventilated and kept very moist with a temperature of about 102°; No. 2 was thoroughly ventilated, not quite so moist, and kept at about 104°. The eggs were as they were laid placed in No. 1 and left there for eight days. The fertile eggs were then moved into No. 2, where they remained for the residue of the period of incubation.

This system worked fairly well, but there were two points capable of improvement; firstly, placing cold eggs amongst those some days advanced in the hatching process was objectionable; and secondly, the necessity of keeping two incubators at work involved much extra trouble. I wished for a machine which would combine in itself the qualities of the two incubators, and would also be suitable for ordinary fanciers who cannot possibly set ninety eggs at a time, but only a few each day.

The idea of a machine with two drawers, the one ventilated and the other unventilated, at once occurred to me, but I also thought there would be considerable difficulty in maintaining an equal temperature in two drawers deriving their heat from the same source but under dissimilar conditions as to ventilation. It also struck me that this unevenness of temperature might be, to a great extent, corrected by the eggs in the ventilated drawer being well on in the hatching process, and thus throwing out some heat themselves, while those in the unventilated drawer, not yet having an independent blood circulation, would absorb much of the superfluous heat.

I was ignorant as to how far these conditions would affect the result, while I knew from experience that a greater or less space between the eggs and the bottom of the cistern caused a material difference in the temperature. I therefore came to the conclusion that, by having the false bottoms of the drawers made capable of being raised and lowered by means of screws, any inequality of temperature might be met by increasing or diminishing the distance between the eggs and the source of heat.

A moveable division in the unventilated drawer would, I thought, obviate the difficulty as to putting cold eggs into the machine. I talked the matter over with Mr. Christy, and the result of our conversation was the construction of "the Fancier" hydro-incubator in an experimental form. A division was inserted in the drawer space of an ordinary ninety-egg hydro-incubator so as to accommodate two drawers, No. 1 containing thirty-six eggs, No. 2 containing forty-eight eggs. The false bottoms of both these drawers were made to move up and down to the extent of 2 inches, and in No. 1 there was a moveable division which fitted into slits cut in the side of the drawer. No. 1 was unventilated, No. 2 thoroughly ventilated.

This incubator was sent to my rooms at Herne Hill on the 26th of November; I at once got it to work, and on the 1st December I put a dozen eggs (Leghorns and farm cross) in No. 1. On the 2nd December I placed in twelve eggs more, and on the 3rd another dozen. The second and third lots were each for one day kept shut off from the rest of the drawer by the division. As soon as each dozen had been in nine days they were taken out of No. 1, tested for fertility, and the fertile eggs placed in No. 2. On the 14th, 17th, 21st, and 24th December respectively an additional dozen eggs were put in No. 1. Twenty-eight of the first three dozen contained living germs when tested (the remaining eight being clear or addled), and there was therefore at one period one drawer full of eggs only a few days in, and the other containing twenty-eight eggs with well-developed chicks in them. I

found that, although when both drawers were empty No. 1 was about 2° hotter than No. 2, yet when the stage already indicated was reached, No. 1 at an equal distance from the cistern was 5° or 6° colder than No. 2. I therefore gradually raised No. 1 and lowered No. 2. I found it necessary to go to the extreme limit of difference of height possible, and to put No. 1 two inches nearer the cistern than No. 2, before I could attain the heat I desired—namely, 102° in No. 1 and 104° in No. 2. The screws, however, gave me sufficient scope to obtain the desired temperatures, and have since afforded the means of meeting any variations caused by the removal of live chicks.

Now as to the hatching results. From the twenty-eight fertile eggs twenty-four fine healthy chicks hatched out, generally a day before they were due. One of the remaining four eggs produced a live chick, but it was a monstrosity and died at once. Two others died in the shell, when ready to hatch out, from their heads being so placed that they could not reach the shell with their beaks. The fourth was the only failure which could be attributed to any fault in the hatching, as it contained a dead chick of about seventeen or eighteen days' growth.

These results I consider most satisfactory; and indeed taking into account the season of the year, that the eggs had travelled by rail from Brandon, and that some of the second dozen were at least a week laid, I think the hatch wonderful. I have only to add that by the method of working which I adopted—namely, keeping a small gas stove constantly alight in the fireplace with a four-gallon pot of water upon it, and replacing the boiling water used by what I drew off from the incubator, the trouble and time consumed were reduced to a minimum; the atmosphere of my room was not in any way vitiated, and the expense was kept low. The average consumption of water was three gallons night and morning. The temperature of the room varied from 50° to 60°.

I believe that Messrs. Christy intend to make "the Fancier" rather larger than the experimental one—namely, to contain one hundred eggs in all, forty-five in No. 1, and fifty-five in No. 2 or thereabouts. This would give a steady setting capacity of five eggs per day, or fifteen every third day, and would probably suit the wants of many who now cannot use an incubator. "The Fancier" could of course be fitted with the new heating apparatus.—ALEX. COMYNS.

#### THE POULTRY CLUB.

THE last Committee meeting of the Poultry Club for 1880 was held on the 29th ult. at the Clarendon Hotel, Oxford. Present, the President (Hon. and Rev. F. G. Dutton), S. Lucas, and O. E. Cresswell. The Hon. Secretary reported that he had recovered for two members of the Club sums due to them from two defaulting shows. Complaints were laid against three other shows from members of the Club, and the Hon. Secretary was requested to inquire into them. The following new members were elected:—Mr. R. W. Brett, Gas Works, Hertford; The Hon. Mrs. Somerset Calthorpe, Ryde, Isle of Wight; Mr. L. Ponsonby, Old Parks Farm, Charlton, Malmesbury; and Mr. A. Stevens, Penhill, Cardiff, an associate member, was elected a full member. A communication concerning the management of a large show was considered. It was decided that the drawing-up of a circular, in conformity to the resolution passed at the Crystal Palace, would more properly be left to the enlarged Committee, which might probably meet for the first time at Wolverhampton during the time of the show.

#### ABERDEEN SHOW.

THE fifteenth annual Exhibition of the Northern Poultry and Pigeon Club was held at Aberdeen on the 6th, 7th, and 8th inst. It was very successful both in regard to the number and quality of the exhibits, and the management was all that could be desired. Owing to a rule that not less than six entries should in any class form a competition, several classes were deleted and the entry fees returned. We think it would be better to allow the classes in such cases to stand, but to diminish the prize money or withhold some of the prizes. One of Mr. Tomlinson's incubators was specially purchased by the Committee, and with a Christy already in hand was used for the purpose of hatching out birds at the Show. The incubators were opened at regular hours. They attracted much attention, and considering the circumstances gave very fair results. Mr. Raines judged the poultry, Mr. Alexander Frame the Pigeons.

**BRAHMAS.**—Any Colour Cocks (seven) were all Darks, and not good as a class, coarseness of comb being almost general. First (Edmonston) large, shapely, and good in colour, but coarse and uneven in comb and carrying too much tail and hook. Second (Lind) good in size, but of very defective colour. Third and fourth (Wilson) only moderate, the former, however having the only neat comb in the class; h.c., Mrs. Suter; c., Forbes. Hens (sixteen) were again all

Darks, and for size and shape were mostly of a good type. We think size has been properly kept in view in the north, and not sacrificed to mere peneilling. First (Sandeman) is, we believe a well-known winner. She is very pure in colour and well marked, but looks overdone. Second (Sandeman) another very good one of similar type, but deficient in foot feather. Third (Edmonston) rather brown in shade though well marked. Fourth (Mrs. Suter) same type as the winner, but not so good in marking; h.e., Edmonston, Mrs. Bennett (2); c., Edmonston, Duncan, Wilson, Duguid. Cockerels (fourteen) were, with the exception of one unnoticed bird, all Darks again, and a good class. First-and-cup (Edmonston) a good cockerel in nearly all points, his faults being a rather uneven comb and rather too much leg. Second (Toplis & Duff) good size, but not very shapely. Third and fourth (Edmonston) both good-sized hooked cockerels of quality, the latter very neat in head; v.h.c. (Mrs. Bennett), very shapely and neat in head, the best Brahma in the class, but too dark in hackle, and grizzled; h.e., Sandeman, Mrs. Suter, Toplis & Duff; c., Mrs. Suter (2). Pullets (fourteen) were as a class, like the hens, good in size and shape, in these respects far surpassing the southern birds, but not so good in marking. First and second (Mrs. Bennett), both exceptionally large and of good colour with fairly clear markings, and rightly placed. Third (Sandeman) rather deficient in breast marking. Fourth (Edmonston) shapely, and good in breast marking, but not clear on wings and back; v.h.c. and h.c., Mrs. Suter; h.c., Edmonston (2); c., Forbes Robertson.

**COCHINS.**—Any Colour Cocks (seven) were a fairly good class. First (Mrs. A. Davidson) a large Buff, rather hollow in breast and white in tail, entered at 10s. and bought at £1; a bargain surely. Second, Forsyth Grant. Third and fourth (Mrs. Steven) all very good Whites rightly placed; c. (Reid) a Buff. Hens (seven) showed a considerable failure in colour in the Buffs, to which the first three prizes went. First-and-cup (Mrs. Davidson) a large, shapely, and well fluffed bird, of a lemon shade, but mossy. Second (Steven) a similar stamp, but darker and worse in colour. Third (C. Brown) was rather better in colour, but carried too much tail. Fourth (Mrs. Steven) a good White; v.h.c. and c., Mrs. Davidson; h.c., Reid. Cockerels (eight) were rather a poor class. First (Mrs. Forsyth Grant) a large Buff, heavy in comb and uneven in colour. Second (Mrs. Steven) a neat White very free from yellow. Third (C. Brown) a moderate Buff. Fourth (Mrs. Davidson) a shapely Buff of the Dark sort; v.h.c., Mrs. Davidson; h.c. and c., Pickeman (Whites). Pullets.—No competition.

**DORKINGS.**—Coloured except Silver-Grey Cocks (six) contained some really good birds. First (J. Cran) a fine-shaped full-breasted Dark cock; he won the cup at Elgin last year as a cockerel for the best Dorking in the show; his comb was over, but only from the frost, we believe. One of Mr. Smyth's breed, we understand. Second (Cathcart) another Dark of good size but rather too upstanding. Third (Charles) another good Dark cock of Messrs. Smyth's strain, the cup-winner at Inverurie, we believe. Fourth (Snowie) another Dark of very nice quality, and might have stood higher but for one spur being outside; v.h.c. (J. Cran), a good-sized one light in colour. Hens (eleven) were a remarkably good class. First (J. Cran) a large-bodied shapely hen of very good colour with nice feet; second at Elgin, we believe. Second (Cathcart) another large hen, not quite so good in shape or colour as the winner; first at Edinburgh. Third (Cathcart) the third Birmingham hen, we think. Fourth (Cathcart) not quite so large, but good in colour; v.h.c., Charles, Cran; h.c., Toplis & Duff; c., Lind. Cockerels (nine) were not so good as a class as the old birds. First (J. Cran) a large bird with good comb and ear-lobes, and very white feet, but rather dark in colour and long in leg; he also came from Londonderry. Second (J. Cran) the Elgin and Inverness winner, in fine condition; will make a very good one with a little more age. Third (Toplis & Duff) the Dundee and Forfar winner, good in size and shape, but shockingly dark feet. Fourth (Ovens); v.h.c. (Cathcart) we preferred to fourth; h.c., Charles, Mrs. Snowie, Mrs. Morrison. Pullets (seventeen) were a very good class indeed, except that dark feet were very prevalent. We did not think them well judged. First (Anderson) rather long in leg and black feet. Second (Toplis & Duff) a large shapely pullet, but dark feet and one spur right outside. Third (ditto) a good pullet but for dark feet again. Fourth (Snowie) still another dark-footed bird; v.h.c., Cathcart (2); h.c., Charles, and 151, Cran, unnoticed, we liked best in the class; they were both good in size and colour, and had white feet; after them the prizewinners would have been rightly placed; c., Snowie, Smith, Morrison. Silver-Grey or White Cocks (six) were all Silvers of good quality. First (Morris) a grand bird, one of the largest and most massive for a Silver we have seen for some time. He might with advantage be more silvery in shade. Second (Cran) a cockerel, good in head and feet but hardly body enough. Third (Angus) another good old bird, splashed on breast. Fourth (Ovens) rather yellow on back. Hens (eleven) were another strong class of Silvers. First (Morris) a grand Dorking indeed but down behind, which some thought should have thrown her out. Second (J. Cran) the Edinburgh and Elgin winner, not so massive as first, but still a large fine hen of pure colour. Third (Mrs. Robertson) a squarely made shapely bird of medium size. Fourth (Black) also a good one though smaller; v.h.c. (Angus) might have stood fourth but for a corn on one foot; Ovens, Meff; h.c., Geddes; c., Morris. Cockerels (eighteen) were again all Silvers and a good class. First (Annand) nice in shape and colour but too long in leg.

Second (J. Cran) good in body and feet, but not quite right in colour, and comb over. Third (Ovens) a little too long in leg and squirrel-tailed, good in body. Fourth (Masson) the best shape in the class, but yellow and dark-footed; v.h.c., Black, Annand; h.c., Meff, Black. *Pullets* (twenty) were a very good class, Silvers being alone represented. First (Annand) the Elgin winner, a grand pullet indeed in all points. Second (Meff) a very neat good-coloured pullet, but far behind first. Third (Morris) not quite so clear in colour, long in leg, with dark feet. Fourth (Morris) squarely made and good in colour, we preferred her to third; v.h.c., Ovens, Annand; h.c., Black, Cran, Ovens; c., Meff and Duffus.

**GAME.—Black or Brown Red Cocks** (ten). First-and-cup (Duncan) a very reachy stylish Black Red, brown in fluff. Second (Park) a Brown Red, long in reach again and laced on breast. Third (Noble) a Black Red of similar type to the winner, but not so stylish. Fourth (Young) a Brown Red, nicely laced on breast but rather dull in colour. *Hens* (seven).—First (Allan) a powerful-looking hard-feathered Brown Red. Second (Noble) a moderate Black Red. Third (Glen) a reachy Black Red, not very clear in colour. Fourth (Park) a Brown Red again, more or less laced all over. *Any Other Variety Cocks*.—No competition. *Hens* (six) were not a strong class. First (Maxwell) a moderate willow-legged Pile. Second (Cable) another of the same sort, as also were third and fourth (Noble).

**HOUDANS.—Cocks** (eight) contained some fine birds. First (Adams) a grand-bodied bird of fine colour, but rather heavy in comb. Second (King) good in crest, comb, and colour, but slight and long in leg. Third (King) good size, but coarse in head again. Fourth (Massie) smaller but neat and shapely, failing in crest and comb; v.h.c., Carter and Thompson. *Hens* (thirteen) were a remarkably fine class. First (Adams) very nice in marking, good in crest and muffling, but hardly massive enough. Second (Mrs. Philip Turner) a beautiful crest with good shape and colour; on the whole we preferred her to first. Third (Mrs. Robinson) a solidly made hen, rather light in colour. Fourth (Mrs. P. Turner) a moderate bird. All the noticed birds were really good v.h.c., Turner, Carter; h.c., Turner, King; c., Chalmers. *Cockerels* (nine) were again a fine class. First (Mrs. P. Turner) the Crystal Palace and Birmingham winner looking well. Second (Adams) a good-bodied bird, rather too upstanding, bad fifth toe, and spurs outside. Third (Adams) a stylish cockerel, perhaps a trifle long in leg and deficient in crest. Fourth (King) a grand Houdan of the Dark sort, rather rough in comb; h.c., Craib & Reid; c., Masson. *Pullets* (eleven) were another fine class. First (Mrs. Turner) very good in crest, muffling, and colour, but deficient in chest. Second (Mrs. Robinson) better in shape but light in colour. Third (Adams) a good crest but not very large. Fourth (King) a very shapely Dark pullet, good in all points; h.c., King, Masson; c., Chalmers.

**HAMBURGHES.—Silver-spangled.—Cocks** (ten) showed, as a rule, too much comb. First (Campbell) good in colour and stylish, but rather large in comb and lobe. Second (Cowie & Fowler) a very ugly comb and red lobes, for which reasons we much preferred third (Campbell), which had a clear white lobe, and was fair in comb. Fourth (Anderson) a nice ear-lobe, but only moderate in marking; v.h.c., Mr. Matthew Mearns; h.c., Campbell, Ogg. *Hens* (eight).—Cup and all four prizes went to Mr. Campbell with birds good in most points, except that they had heavy combs; h.c., Lawson, Ogg. *Gold-spangled.—Cocks* (six) were not a strong class. First (Mearns) the Elgin winner in the Variety class, very stylish and good in colour, moderate comb and lobe. Second (Lowe & Kidd) a shocking comb, and rather large in body. Third (Walker) again bad in comb, but good in ear and colour; only moderate in marking. Fourth (Andrew). *Hens*.—No competition. *Gold or Silver-pencilled.—Cocks* (six) were only a fair class. First (Mearns) a smart cockerel, neat in head and lobe, and good in colour. Second (Leslie) nice lobe, moderate comb, colour fair. Third (Mitchell) clear in lobe, but rough in comb and bad in tail. Fourth (W. Smith) a moderate all round bird. *Hens* (eight) a moderate class. First (Meek) a nicely marked hen, good in comb and lobe. Second (Mitchell) not so good in breast marking. Third (A. Smith) only moderate. *Black.—Cocks* (eight) were far too heavy in comb as a rule. First (Winn) white lobe, and very brilliant condition; very heavy comb. Second (Cowie) rather more stylish and in good gloss, but heavy about the head. Third (Leslie) a smaller comb, but one very bad lobe. Fourth (Leslie) very smart, and not so bad in comb as the rest; we should have placed him higher. h.c., Leslie. *Hens* (twelve) were better as a class than the cocks. First (Terris) in good bloom and fairly neat in head, as also was second (Stewart). Third (Winn) failed rather in condition, though very neat in lobe. Fourth (Leslie) neat head and lobe, but dull in colour; v.h.c. Mrs. Wilson, Cowie; h.c., Winn, Chalmers.

**LANGSHANS.—Cocks** (six) were a fine class. First (Sleigh) a large glossy bird rather long in the shanks, and these almost devoid of feathers. Second (Bennett) of similar stamp, though not so bright in colour. Third (Tait) not so long in leg as the other two, and in brilliant condition, but with a rather large tail. Fourth (J. Cran) of the long-legged sort again; h.c., Mrs. Wade; c., Pirrie. *Hens* (six) a wonderfully fine class. First-and-cup (Mrs. Bennett) far the best Langshan we have ever seen, of great size, full breast, shapely and neat in head, moderate foot feather, of the same type as the winning cock. Second (Mrs. Bennett) of good size, but not very bright in colour, and too upstanding. Third (J. Wilson) in nice bloom, but slight in build. Fourth (Sleigh) very shapely and in fine bloom, but wanting foot feather. *Cockerels* (eighteen) were again a very good

class. First (Morris) large and in fine bloom, but too long in leg. Second (Mrs. Bennett) glossy, but long in leg and squirrel-tailed. Third (Watson) a good-bodied bird. Fourth (Sleigh) moderate; v.h.c., Linton; h.c., Tait (2) Pirrie; c., Sleigh. *Pullets* (fifteen) as a class were good and showed wonderful gloss and condition. First (Morris) square and shapely, but short of feather. Second (Bennett) another large good-shaped one, rather too long in leg. Third (J. Cran) same type as first. Fourth (Tait) very shapely, but perhaps too much of a Cochon type; v.h.c., Mrs. Grant; h.c., Strachan, Mrs. Bennett; c., Linton.

**LEGHORNS.—Cocks** (six) were not a good class. First (Blair and McDonald) a well-made richly-coloured Brown, with a huge comb and heavy lobe. Second (W. Fraser) a good White in all other points, but pink in lobe. Third (Robertson & Douglas) a Brown, fair in colour but rough in lobe, and comb over. Fourth (Anderson) a very dirty White, quite out of condition. *Hens* (nine) a good class. First, third, and fourth went to Mr. W. Fraser for Whites, good in all points. Second (Robertson & Douglas) a very large White, failing in lobe and colour of leg; h.c., W. Fraser.

**POLANDS.—White-crested Blacks** at the first look round struck us as wonderful classes, and upon consulting our catalogue we were surprised to find that all of the twenty birds (ten cocks and ten hens) shown belonged to the same exhibitor. We fancy that nowhere else than in Aberdeen could such a collection from one yard be seen as the birds sent out by Mrs. Henderson to this Show. Seven in each class were noticed, and deservedly so, by the Judge; and the cup for the best four birds in any one class by one exhibitor (Leghorns, Polands, or Spanish) of necessity went to Mrs. Henderson.

**SPANISH.—Cocks**.—No competition. *Hens* (six) were, except the winner, poor. First (Biset) a very nice pullet with a large flat lobe. Second (Ogg) a hen very good in face, but with a humped back and too long in leg. Third (Duncan) and fourth (Hunter) only moderate.

**ANY OTHER VARIETY**.—No competition.

**BANTAMS.—Game, Black, or Brown Red Cocks** (fifteen) were all Black Reds and a fair class. First (Grieve) a very shapely bird, good in reach but a trifle dull in colour. Second (Frew) another very smart bird, carrying his wings rather low. Third (Duncan and Kennedy) very dull in colour and apparently out of sorts. Fourth (King) in brilliant condition, but rather large, and showing some brown on his breast; c., Horne, Robertson. *Hens* (ten) were again all Black Reds and a moderate class. First-and-cup (Duncan and Kennedy) a neat hard-feathered bird, the best in colour. Second (Robertson) good in reach, as also was third (Carter and Thompson). Fourth (Grieve); h.c., Frew; c., Anderson. *Game Any Other Variety Cocks* were a moderate class of six. First and Fourth (Duncan and Kennedy) both willow-legged Piles. Second (Mitchell) a yellow-legged one, as also were third (J. Adam); and h.c., W. Adam. *Hens*.—No competition. *Black Cocks and Hens* (ten) were all Rosecombs and fair as a class. First (Grant) neat in head, nice in lobe, and in fine condition, but the cock a trifle large. Second (Mr. Andrew) good in lobe, but the cock rough in comb and the hen dull in colour. Third (Pirie) not in condition. Fourth (Craig); h.c., Ogg, McAndrew; c., Miss Frew. *Any Other Variety*.—No competition.

**DUCKS.—Aylesbury**.—No competition. *Any Other Variety* (ten) were a fair class. First (Mrs. Turner), good Pekins. Second (Mrs. Wade) Pekins again. Third (Fenton) Muscovies. Fourth (Angus) Rouens; v.h.c., Shepherd (Rouens); h.c., Mrs. Jack, Mrs. Barclay, Reid (all Rouens), Fenton (Muscovy). There was no competition in the classes for Turkeys, Geese, and Crossbred fowls respectively.

#### PIGEONS.

**POUTERS.—Blue or Black-pied.—Cocks** (eight).—All the winners were very fine and well placed. First (Mitchell), second (Robb), and third (Johnston) were all Blacks. Fourth (Black) a Blue. *Hens* (eight).—A very fine class. First, second, and fourth Blacks, and third a Blue, all came from the lofts of Mr. Mitchell of Glasgow; c., Mitchell (Blue). *Red or Yellow-pied.—Cocks*.—No competition. *Hens*.—No competition. *Any Other Colour.—Cocks* (nine).—The winners were all fine specimens. First (Phillips) a grand Mealy. Second (Robb) a Strawberry. Third (Towers); fourth (Hay), both Whites. *Hens* (nine) were another good class. First (Mitchell) a Black Chequer, second (Mitchell) a Red Chequer, third (Phillips) a Silver, and fourth (Hay) a White, were all true Pouters, small in girth, long in feather, and of good carriage. *Any Colour Cocks bred in 1880* (eleven).—First (Mitchell) a grand Blue. Second (Black) a Black, wanting a little in crop, but otherwise a good one. Third (Robb) a fine Black. Fourth (Wilson) a good Blue; v.h.c., Mitchell (Red-pied); h.c. and c., Johnston (Black). *Hens bred in 1880* (eight) were another very good class. First (Thomson) and second (Johnston) were Blacks, third (Wilson) and fourth (Robb) Blues; v.b.c., Mitchell (Blue); h.c., Towers (Red-pied); c., Phillips (Blue).

**DRAGOONS.—Cocks or Hens** (twelve), besides the winners, contained some splendid birds, worthy of a place almost at any show. First (Leith) a Yellow. Second (M'Boyle). Third (Johnston) Blues. Fourth (Leith) Red; h.c., Yardley; c. Findlay (a fine Blue) we preferred to second.

**BARBS AND CARRIERS.—Cocks or Hens**.—No competition.

**FANTAILS.—Cocks or Hens** (nine) contained some very fine specimens indeed. First, second, and v.h.c. (Stevenson) Whites. Third (Stevenson) a Black and White. Fourth (Glenday) a White.

**JACOBINS** were both splendid classes, and made such a show as has seldom been seen in Scotland. *Cocks* (fifteen).—The winners were all very good birds indeed. First (Jeffery) one of the best coloured Blacks we have ever seen. Second (Coalston) a Yellow. Third (Dale) a Red. Fourth (Weyman & Buchanan) a Yellow again; v.h.c., Weyman & Buchanan (Yellow); h.c., Weyman & Buchanan (Red), Coalston (Red); c., Marshall (Red). *Hens* (seventeen) also contained many grand birds. First-and-cup (Dixon) a grand little Yellow with fine feather tightly put on. Second (Jeffery) a Yellow, and third (Coalston) a Red, were also fine specimens. Fourth (Cowe) a Black, loose, but very long in feather; v.h.c., Weyman & Buchanan, Jeffery (Yellow), Dale (Red); h.c., M'Boyle (Red); c., Dale (Red).

**OWLS.**—*English.*—*Cocks or Hens* (fourteen), a good class. First (Wardle) was rather strong and rough a bird for our taste, we should not have placed him so high. Second, Duthie; third, Duffus; fourth, Marshall; v.h.c., Wardle, Smith, Duthie, Duffus; h.c., Marshall; c., (Findlay), we thought about the best bird in the class.

**TURBITS.**—*Cocks or Hens* (sixteen).—The winners, though in some cases not the best in colour, won by head properties. First (Dale), second (Glenday), third (Marshall), fourth (Marshall) were all Blues; h.c., Crabb (Yellow), Bruce (Blue); c., Wardle (Silver).

**TRUMPETERS.**—*Cocks or Hens* (seven) were all of the Russian type, and only of fair quality, some of them appearing overshadowed. First (Wardle) and second (Yardley) Black Mottles. Third (Dixon) and fourth (Gatty) Blacks; v.h.c. (Wardle and Gatty) also Blacks.

**NUNS.**—*Cocks or Hens* (thirteen).—The winners were well placed. First, Johnston; second, Dale; third, Wardle; fourth, Findlay. Some of the others had had nature assisted, and the Judge did not award any commendations.

**ARCHANGELS.**—*Cocks or Hens* (eleven).—One of the finest classes we have ever seen, the winners being splendid in lustre. First (Cowe) was the second Brighton bird, and quickly claimed at seven guineas. Second, Cowe; third, Gatty; fourth, Marshall; v.h.c., Cowe, Duffus; h.c., Cowe; c., Cowe (2).

**ANTWERPS.**—*Cocks or Hens* (ten) were only moderate in quality. First (Yardley) Red Mottle. Second (Yardley) Silver Dun. Third (Dale) Red Mottle. Fourth (M'Donald) Silver Dun; h.c., Cowe (Silver Dun); c., Glenday (Red Mottle).

**SHORT-FACED TUMBLERS.**—*Cocks or Hens* (fifteen) were as good a class as we have ever seen in the north. The principal winners had already taken leading places at Oxford and the Palace. Mr. Macfarlane of Stirling took first, second, and third, and also the cup for most points in any class of Pigeons with fine Almonds. Fourth (Coalston) a Red Agate; v.h.c., Macfarlane (2, Almonds); h.c., Yardley (2, Almonds), Macfarlane (Red Agate); c., Leith (Almond).

**ANY OTHER VARIETY.**—*Cocks or Hens* (fifteen) contained some really fine birds. First (Gatty) a grand Yellow Magpie. Second (Gatty) a very fine Frillback. Third (Mrs. Grant) a Red Magpie. Fourth (Jeffery) a Fairy Spot; v.h.c., Mrs. Grant (Black Magpie); h.c., Crabb (Swallow), Wardle (Satin), Yardley. There were many fine birds unnoticed, amongst them 645 (Cowe), a beautiful little African Owl.

**COMMON TUMBLERS.**—*Cocks or Hens* (nineteen).—First (Glenday) a Beard. Second (Glenday) a Mottle. Third (Cowe) an Almond. Fourth (M'Donald) a Bald; v.h.c., Miss Frew (White); c., Begg, Marshall.

#### CHRISTY'S HYDRO-INCUBATORS AT CANTERBURY.

THE Committee of the Canterbury Poultry Show wish to give publicity through your columns to their opinion of Messrs. T. Christy & Co.'s hydro-incubators, which that firm lately lent them for the purpose of making a personal trial of, and showing the machine at work to the visitors to the Show, and giving explanations of its management. Dr. Pittoch took chief charge of the experiments made, and was able on the morning of the Show to produce from the hydro-incubator about twenty live chickens, which were transferred to the rearing mother, and caused great interest and much pleasure to the spectators.

The Committee are desirous of making public their great satisfaction with the machine and its mode of working. Its success was amply demonstrated by the results. There were other incubating machines exhibited, but all failed to produce chickens, save Christy's hydro-incubator.—WM. PLUMMER, *Chairman*; GEORGE P. LADD, *Hon. Sec.*

#### NATIONAL PERISTERONIC SOCIETY.

THE annual Show of this Society was held at the Crystal Palace on the Tuesday and Wednesday of this week. Both as to the quantity and quality of the exhibits it could in most classes bear comparison with its predecessors.

*Pouters* were certainly the best collection the Society has yet produced. Amongst them we noted specially an excellent Yellow hen of Mr. Combes, also a fine upstanding Red of Mr. Gill's, the winner of numerous prizes. This exhibitor showed many other good birds. *Carriers*, as is usual here, were large in quantity and excellent in quality. Mr. Hedley exhibited many excellent birds, and was well supported by Dr. Square of Plymouth and other celebrated Carrier

fanciers. Mr. Poland's Whites were specially worthy of note on account of the scarcity of the colour. In Almond *Tumblers*, generally so largely shown here, we missed with regret the well-known birds of Mr. Jayne, who formerly was so large an exhibitor. Mr. Merck, however, sent some very charming specimens, particularly noticeable for their colour. *Baldheads* produced two very pretty pens from Mr. Murphy. There were a few pens of good *Turbits*, a class of birds always much admired. In *Jacobins* the entries were not so large as on previous occasions, and we fancy we have seen better quality on the whole. Mr. Hedley showed some very good *Barbs*. We missed the White *Fantails*, always so attractive to the ladies; but Mr. P. H. Jones showed a fine pen of Blues, also two Laced *Fantails*, a very uncommon variety. Amongst uncommon birds we may note two pens of Mr. O'Neef's, the one termed *Ancients* and the other *Modenas*. We imagine the latter are derived from the small Leghorn Runts. There were seven pens of English *Owls* exhibited by Messrs. Thirkell, P. H. Jones, Esquilant, Vero Shaw, and Van Senden. Fancy *Antwerps* were in great force, and Mr. Waterhouse showed some excellent specimens. This gentleman also sent a pen of very charming *Turbiteens*, *Bluettes*, &c. Mr. Price sent some very large *Runts*. The *Homing Pigeons*, as might be expected from the great popularity this breed has attained of late years, were very largely represented. Amongst the specimens were birds that had flown distances from three hundred to nine hundred miles; the chief exhibitors were Messrs. Tegetmeier, Logan, Winsor, and Carver. *Dragoons* of all colours were well represented. Amongst them there were a pen of Blues, the celebrated Chequer of Mr. Howard, some fine Grizzles of Dr. Dwelly, and some excellent Reds and Yellows of Mr. Leith.

#### OUR LETTER BOX.

**Cropping Arable Land (J. E.).**—An acre of land to produce food for dairy cows may be cropped as follows:—quarter of acre of Rye, followed by James' Intermediate Carrots; quarter of acre Trifolium, followed by Cattle Cabbage; half of acre Mangold, fallow and manured for. The green crops, &c., to be reversed each year with the Mangold crop.

**Grass for Permanent Pastures (X., Sidmouth).**—Grass seeds for laying down an acre of land of rather stiff loam into permanent pasture may be as follow:—8 lbs. of Dwarf Permanent Dutch Clover; 4 lbs. of Timothy Grass, or 12 lbs. of heavy seed; 4 lbs. Cocksfoot; 4 lbs. Hard Fescue; 4 lbs. Meadow Fescue; 6 lbs. Pacey's Perennial Rye Grass; or 18 lbs. of light seeds, the light and heavy seeds to be sown separately. The time of sowing, the method of preparing the land with manures, &c., is given with full information in this Journal on February 5th, 12th, and 19th, 1880. The numbers can be obtained at the office, price 3½d. each by post.

**Tortoises in Winter (Distressed Tortoise).**—There are a great number of species, most of which are natives of warm regions of the globe; but those that live in colder climates burrow and sleep during the winter. They are quiet inoffensive animals, extremely tenacious of life, and remarkable for longevity. Individuals are stated upon good authority to have lived upwards of two hundred years! The common tortoise, or *tartaruga*, *Testuda græca*, is a native of the south of Europe, and almost all the countries bordering on the Mediterranean. It is found in the islands of the Archipelago, Corsica, Sardinia, and in Africa, and is thought to be more common in Greece than elsewhere. It is from 6 to 8 inches long, and weighs about 48 ozs. This species is often brought to this country, and kept in gardens. One was brought to the archiepiscopal garden at Lambeth, in the time of Laud, in 1633, where it lived till 1753, owing its death then more to neglect than the effect of age. You had better place your pet in the greenhouse, and supply it with food. They live mostly on vegetables, but will eat almost anything, including bread soaked in milk.

#### METEOROLOGICAL OBSERVATIONS.

CAMDEN SQUARE, LONDON.

#### REMARKS.

2nd.—Overcast, damp, mild morning; dark and foggy in afternoon; clearer in evening, but foggy again after 9 P.M.  
3rd.—Misty, dark, and dull until 1 P.M.; afternoon fine and mild.  
4th.—Fair, but overcast generally.  
5th.—Fine and bright, with very cold east wind.  
6th.—Very fine, with bright sunshine all day; strong east wind.  
7th.—Fair, bright, and cold.  
8th.—Morning cold and overcast; sunshine in afternoon; fine evening.  
Barometer very high and steady; temperature rather below the previous week, and almost exactly the average. Direction of wind generally east, but usually light. No rain during the week.—G. J. SYMONS.

## FORCING VINES IN POTS.

VINES in pots are now very popular and largely grown for supplying early Grapes, and the practice is doubtless advantageous to the health of permanent Vines that would but for these be subjected to much earlier forcing. Those known as cut-backs are the best for very early work if grown at home, otherwise those grown from eyes in one season in the nurseries are as good. If Vines are cut-backs and home-grown they can be started into growth at any time, and in consequence the wood will be ripened earlier and better than those from eyes. The principal point where pot Vines are employed for early work is to have them ripe, so that they can enjoy a good rest before forcing time; this is most essential to success, and renders the work afterwards much more easy.

When grown from eyes it is difficult to have them ripened sufficiently early to allow a good rest before starting, for if the Vines only lose their foliage and are started almost at once success cannot be expected. In the majority of cases they are a long time commencing growth, and under such circumstances are liable to be overforced in their early stages and break irregularly; but with well-rested cut-backs success is more certain in every way.

There are many systems of forcing the Vines, one being starting them by applying bottom heat, and another without it. Success can be attained by both, but when the former system is carried out it requires to be done by practical men, or the result may be a failure. A bed of leaves and litter is made up in the majority of cases by those who supply the bottom heat they think necessary to cause the roots to grow, while the canes have a similar temperature to those started without it. By this course the roots are forced unnaturally into activity before any growth is apparent upon the canes. It is a question if the Vines supplied with bottom heat break into growth much earlier than those started without it, although in one case the roots are active, and in the other they are not. What this early root-action is required for before they have any leaf growth to supply with food I am at a loss to understand. The Grapes will not ripen much earlier than those started without bottom heat. In seasons like those of last year, when the wood of young Vines is not very ripe and bottom heat is applied in forcing them into growth, it is in my opinion critical if not dangerous. As before said, they are liable to be overforced and apparently continue well until the bunches appear and should begin lengthening-out, but if the wood is not fully ripe and the Vines had insufficient rest the bunches invariably curl and turn yellow, while those brought forward

under a more natural system of forcing are not so liable to fail. Last year I forced Vines under both systems, and those grown without bottom heat in their earliest stages were decidedly the better. I have no reason to condemn the bottom-heat system, because the Vines succeeded fairly; but I cannot see the utility of starting the roots before the other portion of the Vines, and I advise those anxious to achieve success to start their Vines without bottom heat. Those started in this way were placed upon ashes, while the principal bed in the same house was filled with fermenting material for the purpose of forcing Rhododendrons, Azaleas, and other plants into flower. The moisture rising from the bed of leaves and litter is a great advantage in assisting the Vines to break regularly.

Those forcing Vines in pots could not do better, if convenient, than make up a bed of leaves for the purpose of supplying a genial heat and moisture, but not to act as bottom heat, in the early stages of forcing. Although I advise starting without the aid of bottom heat, it can be employed with advantage after the roots have naturally commenced growth and the berries are set. Slight bottom heat is then rather an advantage than otherwise, and assists considerably in maintaining root-action, which is necessary for the proper swelling of the berries and the thorough maturation of the crop. Bottom heat if applied after the fruit is set, so far as I am able to judge, would bring them forward quicker, and if any time was lost in starting the deficiency would then be made up. Much of the difficulty of forcing Vines in pots is removed if the canes are ripened early, and when such is the case there is less need than ever for bottom heat in any stage. After a good rest they not only start into growth quicker and earlier, and any system of hard forcing that would under other circumstances have to be applied can be dispensed with, and a crop of Grapes ripened with comparative ease and certainty.

*Potting Matured Vines.*—It is by no means a common practice to remove Vines intended for fruiting from the pots in which they have been grown the previous year into those of a larger size. The system may not be new or original, but I have never seen it carried out until I practised it here in 1879 as an experiment, and was then ridiculed by more than one, who said if the Vines had been plunged in pots of a larger size, and the bottoms knocked out of those in which they were growing, there would have been some sense in the plan. This considerably daunted my courage for a time, and I entertained grave doubts about the success of transferring Vines into larger pots. However, they succeeded so well that I was tempted to try it again last year, which I did with marked success, and can now recommend the system to the readers of the Journal as a safe and satisfactory one. This operation must be carried out with care both in potting and supplying the Vines with water afterwards for some time, or the result may not be very satisfactory.

Grapes can be grown finer in pots both as regards bunch, berry, and flavour—in fact, in all respects when subject to repotting if carefully done—than could be the case if the Vines remained in the pots in which they were grown. After the Vines become established in their new pots they are not so uncertain as when fruited in the pots in which they were grown. They are not so liable to become dry at the roots, or to suffer from too large a supply of water, as is sometimes the case on the other system. Not unfrequently, for fear of erring on the

wrong side, they receive too much water, and at a time when they are being supplied liberally with liquid manure. When repotted they have abundance of substantial food in all stages which would otherwise have to be supplied by means of the watering pot. If liquid manure is applied long after colouring commences the flavour of the Grapes is invariably deficient, and, if not supplied with stimulants, what have the Vines to feed upon in the pots in which they were grown the year previous? When repotted they do not require much feeding. A little can be given according to the richness of the compost and the size of the pots; it can be discontinued at any time, so as not to be any detriment to the flavour of the Grapes.

I must here condemn the system of starting Vines in bottom heat, and having their roots in advance of the top growth, if they are intended to be repotted afterwards. I have tried it, but cannot recommend it: the fresh roots are broken in carrying out the operation and do more harm than good, and the system is dangerous and uncertain. Before potting the soil should be in readiness, and laid for a few days before being used in the house in which the Vines are growing, to be well warmed, so that no check will be occasioned by the use of cold soil. The soil should be rich, and consist of good fibry loam, manure, and small bone dust, and a little coarse sand if needed, or any other ingredients Vine-growers prefer, but the compost given will answer the purpose well. The pots should be well drained and covered with the roughest of the compost or a few horse droppings, and then potting should be proceeded with, the crocks and any loose soil from the surface of the old ball only being removed, disturbing the roots as little as possible. The soil must be pressed firmly into the pots, gradually sloping to the Vine in the centre, and if convenient space should be left for further top-dressing. I have tried reducing the old ball, or, at least, disentangling some of the roots to lay into the new soil, but this is scarcely a safe plan. Before potting, the old balls should be in a thoroughly moist state, so that water will not be necessary for a few days or a week. After potting the Vines can be tied up where they are intended to fruit, and if bottom heat is to be applied after the Grapes are set they can be so arranged in tying that the pots can be drawn forward to the bottom heat without untying. If plunged the watering must not be left to a careless hand, but to one who will use the water pot judiciously, and apply the water with care and caution. Careful watering is needed in all stages, but especially until the pots are well filled with roots.

Some may be inclined to think, if potting after growth has commenced is so beneficial to the production of better Grapes in pots, why not repot them in late summer or early autumn after they commence turning brown at the base and while the roots are active? I may add the roots do not keep in such good and fresh condition in large pots, nor do the canes ripen so quickly and well. In short, they will not produce such satisfactory results if placed in large pots before growth is completed as if the operation is done as detailed above.—  
WILLIAM BARDNEY.

#### AUTUMN FLOWERING OF AURICULAS.

I HAVE to thank Mr. Horner for his notes on this subject at page 2. It is a question of some interest to me, as I intend to add considerably to the comparatively small number of plants which I possess, and as some varieties are so expensive that we wish to make the most of them. Further, Auriculas are not altogether a hobby of my own, as my employer takes a great interest in the plants when in flower, and I wish as many as possible to flower in spring.

I will now call attention to some points in Mr. Horner's reply which I consider may be further discussed. He says that "all Primulas are spring-flowering, earlier or later, and may bloom in autumn, whether the summer has been hot and dry or not." When I wrote I was thinking of *Primula japonica*, *P. cortusoides*, and the varieties of *P. amoena*, which here flower rather in early summer than spring, and do not usually produce a second crop of flowers. With regard to a hot and dry or a cool and wet summer making no difference in this respect, we have the summer of 1879 and 1880 for comparison. Spring flowers did not flower a second time in the former year. Last year second flowering was quite common. What have others to say in this matter?

With regard to Auriculas, I saw it stated in one of the gardening papers some time since that Auriculas were flowering more freely out of season in 1880 than in 1879. If this is the general experience it would prove that a hot or wet summer has a bearing on the question. It was for that reason that I had our Auriculas watered the same as other plants are. I wrote, "I give them abundance of water." Mr. Horner wrongly conceives this to mean keeping them "wet," and how far this idea finds a place in his mind is seen when he condemns keeping them "very wet." No plant unless a native of bogs will thrive if kept in a wet condition at the root. Plants kept in a cool condition and protected from sunshine do not require as often to be watered as other flowers growing in the open; but letting that be understood, our Auriculas received water under like conditions. Mr. Horner has so often obtained high positions at the metropolitan Auricula shows that his dictum rightly carries the greatest weight with it. It will consequently be of interest to be told the exact meaning he gives to the phrase keeping the plants "but very moderately moist." And again, "through the summer I have found them always crisper, stouter, quieter, and greener without much water or exposure to sun." The crispness of the foliage would imply that the flagging stage is not allowed to be arrived at before water is applied, and the state of quietness hinted at would imply that the amount of water Mr. Horner gives his plants has to do with the production or non-production of autumn flowers. I may say we have a capital position for our plants—perfectly open, and yet protected from the sun by thick Holly hedges on the south and west.—R. P. B.

#### VEGETABLES TRIED AT THE EXPERIMENTAL GARDEN AT GIRTORD.

AMONGST some hundreds of varieties of vegetables tested at the Girtford Garden during the past season, many of them novelties, a few came conspicuously to the front, and others would doubtless have obtained prominence but for the exceptionally wet and sunless summer of 1880. This especially applied to outdoor Cucumbers, the trials of which were quite as unsuccessful as in 1879. On the other hand, French Beans, except where affected by the disease recently described by the Rev. M. J. Berkeley in a contemporary, were fairly satisfactory. Potatoes, too, were decidedly better than in the previous year, the crops being large and good, and the early varieties quite free from disease, but some of the second earlies and late sorts, including *Magnum Bonum*, were a good deal affected; in the case of the latter variety arising, doubtless, from the spores being present in the seed tubers which had been grown the previous year on strong and wet land, and consequently at least half the seed became diseased during the winter, although repeatedly looked over. Tomatoes planted out under a south fence were quite free from disease, ripened well, and furnished an excellent supply, which was only checked by the early frosts of October. Vegetable Marrows and Squashes were a wonderful crop, so much so that they became valuable as pig food, and notwithstanding that the young growth was much affected by the fly, the outcome of checks the plants sustained from the cold drying east winds of May. Carrots were, however, much injured by the grub. Turnips, as a rule, were stringy and not of the usual quality; and Onions, especially the autumn-sown varieties, suffered from excess of wet and have not kept well; the crop, however, being large.

The manure used in addition to London stable dung and soot was Clay's fertiliser, which was most effective with Asparagus, French Beans, Vegetable Marrows, Onions, Cauliflowers, and Tomatoes. For Potatoes the best rounds were obtained by applying the fertiliser in combination with burnt rubbish mixed with a small quantity of soot; the rows in which the combination was used showing unmistakably better results than where the constituent stimulants were employed separately. For Peas its effects were more conspicuous in the increase of actual produce than in the vigour and appearance of the plant. Soot and dung, on the other hand, appear, on the light sandy soil of the district, rather to increase the amount of straw and foliage at the expense of produce. I find, however, an application of soot as soon as the plants appear above ground of great advantage, as it tends to promote growth in the early stage, and thereby to protect the young plant from the destructive attacks of the weevil.

The following vegetables deserved especially noting:—

*Asparagus*.—One-year-old imported plants of the Early Purple Argenteuil, planted in April, 1879, on the wide-apart or French system, produced during the past season shoots upwards of half an inch in diameter, and quite equal to the best ordinary "grass" from beds several years old. Growers will find this variety both earlier, quicker in coming to market, of better flavour, and quite

as large as Connover's Colossal. The heads also of the Argentcuil variety are more symmetrical than those of the latter.

**Broad Beans.**—After a second year's trial the continental variety Aquadulce and a Californian congener known as the Megatherium (probably a selection from the first) have the advantage in size over all other Longpods. Some pods of the latter, containing six beans, measured upwards of 14 inches in length; but one of the best for quality, fertility, and appearance is Hardy's Pedigree Green Windsor. Some striking results have been obtained by crossing these varieties *inter se*, and also with the hardy winter sorts.

**Runner Beans.**—The finest of the Scarlet Runner type is the Giant White Prussian, the pods being long, broad, and succulent, and produced in great abundance. A cross between this and the Champion Scarlet Runner, of a similar type, but hardier than the white variety—a sort called Speckled Beauty—is also an acquisition, as it is considered somewhat hardier and earlier, and better able to withstand the spring frosts than the Scarlet Runner. The seed, too, is quite distinct, the colour being white, speckled with blackish brown. Several varieties with black or purple pods were tried and found excellent in flavour, although the colour of the pods precludes their being useful for market.

**Dwarf Kidney Beans.**—The largest-podded of this type were Messrs. Vilmorin's Haricot sabre à très grande cosse, a runner Bean with white seeds and very long pods, which are fleshy and freely produced, the pods containing from six to ten seeds. In Wax or Butter Beans, a new running variety from Messrs. E. G. Henderson & Son proved of excellent quality, the flavour being very rich and buttery. The colour of the pods, which are nearly stringless and succulent, is of a deep lemon yellow; it is the best of all the Wax Beans for flavour. Another excellent Bean of this type (also from Messrs. E. G. Henderson & Son) is Flageolet Dwarf Butter, a dwarf variety with long deep golden yellow-coloured pods of rich flavour. The best of the outdoor dwarf Beans for all purposes as proved in the garden during the past two cool summers was decidedly Early Rachel, a variety adopted on Chiswick recommendation; it is hardy and early, and the pods, which are straight and handsome, are produced freely and continuously over a long period. For market purposes I know of no variety to equal it. M. Chevrier's Haricot à graine verte (received from M. Lebeuf) is a French Bean with a really green seed, a desirable quality when Haricots are cooked in continental fashion. The pods, too, are tender and the flavour delicate.

**Beet.**—The Victoria from Messrs. Haage & Schmidt of Erfurt is an excellent bright crimson variety of medium size, coming in early yet keeping well; flavour rich and free from the usual earthy taste. The foliage is also of a good metallic purple, and the variety comes very true in character.

**Cauliflower.**—Henderson's Wellington proved not only earlier than the Early London, but the heads were of a more delicate white and very compact. It is an excellent market variety, the plants being comparatively hardy, as a good stock of them passed through the winter of 1879–80 without any protection but a slight covering of Bean straw during severe frost.—T. LAXTON, Bedford.

(To be continued.)

#### PELARGONIUM GUILLON MANGILLI.

SINCE Mr. William Taylor's evidence was published of the great value of the double Zonal variety for winter flowering I observe that inquiries relative to it have been sent to the Editors. Varieties of merit have increased so rapidly during the last few years that it is possible that others older but not less useful have almost passed out of cultivation, not always, it is to be feared, on the principle of the "survival of the fittest." Guillon Mangilli does not appear to be in catalogues now, hence those who require plants know not where to obtain them. Although I am not able to supply the information, yet it is possible that something may be learned by applying to Mr. B. S. Williams of Holloway, or Mr. Laxton of Bedford, both of whom were awarded certificates by the Floral Committee of the Royal Horticultural Society for the variety in question three or four years ago. I think also M. Aléatière and Messrs. Dicksons & Co. had similar honours for the same variety. I am unable to say which of the firms of Dicksons submitted plants for adjudication, all I remember is seeing a record in one of the horticultural papers that four certificates were awarded to the exhibitors whose names I have mentioned for Guillon Mangilli. Perhaps the authorities at Chiswick could supply some information on this subject, that would suggest where the variety may be obtained and the name of the raiser of it. I have this variety, and esteem it one of the most valuable for summer decoration on account of its excellent habit, freedom of flowering, and grand trusses of blooms, novel in colour yet rich.

I have not tried it in heat in winter, but Mr. Taylor's experience is sufficient on that point, and enhances considerably the value of a variety that might with advantage be largely grown.—J. D.

#### PEAR BERGAMOTTE HERTRICH.

FRUIT bergamot-shaped, inclining to roundish obovate, even in its outline, except round the stalk, where it is furrowed. Skin very much covered with ashy grey russet, through which the grass-green ground may be seen. On the side next the sun it has a brownish tinge, and there is a patch of thin pale brown russet surrounding the stalk and the eye. Eye with narrow incurved segments set in a shallow and furrowed basin. Stalk three-quarters of an inch long, inserted in a narrow cavity. Flesh yellowish with a greenish tinge under the skin, melting and juicy, with a rich flavour somewhat resembling the Swan's Egg, and a fine aroma. A delicious Pear.

The specimen figured was received from Sir Henry Scudamore Stanhope, Bart., of Holme Lacy, who writes as follows respecting this variety—"I had Bergamotte Hertrich from a French nursery near Orleans in 1865, and have grown it only as a cordon. With me it has been a strong grower and good bearer. The flavour is good. Some years it has not been so melting as others; but this

Fig. 9.

remark applies equally to Ne Plus Meuris, Monarch, and Bergamotte Esperen. It is an excellent keeping Pear, indeed this is one of its valuable qualities; at the same time it is easily brought forward in a warm room. I do not, of course, rank it so high as Glou Morceau or Winter Nelis as a January Pear, but it keeps much longer than either. I give you this merely as my experience of Bergamotte Hertrich. I am always reluctant to recommend Pears that are not generally known, for differences of soil, climate, and situation have so much to do with a Pear succeeding well in one county and being worthless in another."

Bergamotte Hertrich was raised near Bollwyler in Alsace by one Herr Hertrich, and was brought into notice by Messrs. Baumann the celebrated nurserymen of Bollwyler, in whose catalogue we find it in 1863. It is also mentioned in that of M. Simon-Louis of Metz of the same year. In the former its season is said to be from January to August, and in the latter from May till June. The specimen from which our figure is taken was quite ripe at Christmas, but Sir H. Scudamore Stanhope, in the above remarks, gives it a much longer period. All agree in calling it a hardy grower and a great bearer. In Leroy's *Dictionnaire de Pomologie* it is erroneously made synonymous with Bergamotte de Strycker.

**SAXIFRAGA GRANULATA FLORE-PLENE.**—This is a hardy outdoor border plant that I have not seen so specially commended to owners of small gardens as its great merits deserve. The flowers

are snowy white streaked slightly with green, and are produced in such profusion as to hide the foliage, which is of a bright shining green colour. I find it thrives best and throws up a greater quantity of bloom when grown in a shaded moist sandy peat soil, and I have given the plants an occasional supply of liquid manure, with the effect of improving both foliage and flowers. It is not likely to be lost, as the smallest of the tubers will grow on and produce a flowering plant the following year. The principal reason why this plant is not always satisfactory is, because instead of being divided and replanted in prepared soil, it is too often allowed to grow in a mass.—W. J. M., *Clonmel*.

#### THE NATIONAL ROSE SOCIETY.

A MEETING of the General Committee of this Society was held at the Horticultural Club on Tuesday, the 11th inst. The meeting, which was well attended, was presided over by the Rev. John B. M. Camm. The Secretaries read a letter from the Secretary of the Sheffield Rose Society, requesting one of them to attend their next meeting, and it was determined that the invitation should be accepted, and that Mr. D'Ombraïn should visit Sheffield.

The principal business was the appointment of the Executive Committee and the revision of the schedules. The former was a very important matter, as it was pointed out that upon this Committee would devolve the labour of issuing a catalogue of Roses. The aim of the General Committee then was to elect only men who, besides their great knowledge of the subject, would be likely frequently to attend the meetings; hence such skilled rosarians as Mr. Curtis of Torquay, Mr. Cranston of Hereford, Mr. Robert Baker of Exeter, the Rev. E. N. Pochin, and Mr. Jowitt of Hereford were not elected, although the sense of their loss was duly recognised. It was determined, however, in order to reduce this to a minimum that all the drafts of the proposed catalogue should be sent to such important members of the General Committee, with a request that they should alter, add to, and report on them.

The names of those elected to the Executive Committee are Mr. Burnaby Atkins, Mr. Byrom, Mr. Cant, Rev. John B. M. Camm (at present residing in London), Rev. A. Chcales, Mr. Cutbush, Mr. Hawtrey, Rev. J. M. Fuller, Mr. Heywood, Mr. Laing, Mr. Mount, Mr. George Paul, Mr. Prince, Mr. W. G. Sharp, and Mr. Arthur Turner.

Much discussion ensued as to the lines on which we should draw up the catalogue. Some members thought that it should embrace "the genus Rose," at which the Chairman suggested in that case that Mr. Baker of Kew had better write a monograph upon the Rose. It was felt by the majority, however, that something much more modest should be attempted, and that the Committee should report upon exhibition Roses only.

The Sheffield schedule, which was to have been revised, was not touched, as it was thought better to leave it till Mr. D'Ombraïn had been to Sheffield, there being some doubt as to the intentions of the men of the northern town as to the amount of money or plate intended to be given; but the Sydenham schedule was well discussed, although only some minor alterations were made.

Some notice was taken of the determination of the General Manager of the Crystal Palace not to allow the members of the Society a private view. This was felt to be a grievous hardship, as from the crowded state of the Show it is almost impossible for members to see the Roses after once the general public are admitted. The Secretaries explained, however, that they hoped in some way to diminish it by inducing the Crystal Palace authorities to devote more space to the show—in fact, to fill both transepts instead of, as before, only one. But this was felt to be only a palliative, and by no means a removal of our grievance, and ominous growls of "South Kensington another year" were heard from various parts of the room. The objection urged upon the part of the Manager is that the season-ticket holders protested so very strongly against their exclusion that they could not any longer grant the privilege. The writer of these notes is a season-ticket holder, and knows many others who are, and he never heard a complaint; and even if there were complaints, it is by no means an unusual thing for the Manager to receive complaints, and surely not alone the comfort but bare justice of the claims of those who bring their show to the Palace ought to be equally considered.—WYLD SAVAGE.

#### THE VEGETABLE SUPPLY.

YOUR correspondent "WILTSHIRE RECTOR" usually writes interesting and correct articles, but in his "Future Gardening" of your issue of January 6th he writes as follows—"Vegetables most certainly ought to bear a larger portion of our meals, but town population simply cannot get them." If he includes London and its supply he is certainly wrong, and I think should be set right.

In my immediate locality (where a large portion of the land is in market garden cultivation) there are 20 acres of Brussels Sprouts in one field; they are gathered by the stalk, and sent in that way by waggonloads to Spitalfields Market. They are realising at this time from 4d. to 6d. per dozen stalks; on each stalk there is an average of sixty to seventy hard sweet sprouts

as large as bantams' eggs. One stalk is equal to two small dishes, and to my certain knowledge are sold at the west end of London for 6d. a dish, the farmer getting after growing, picking, loading, carting, rail to London (twenty miles), and commission—one halfpenny—the public paying 1s. Another neighbour sent up a short time since a waggonload in sieves of the heads of Brussels Sprouts; they realised 2d. per sieve, thus losing the whole cost, including picking, packing, two miles of carting, twenty miles of rail, and commission.

At this moment I know of 15 acres of prime Savoys all decaying on the ground; they will be eaten off if sheep can be procured to do it.

Onions are grown here in large quantities and are repeatedly unsaleable in London; they are carted away for manure, having decayed in the clamps by hundreds of bushels.

I think I have shown that it is not the shortness of produce that prevents the poor getting a good and necessary supply of fresh vegetables.

I have suggested to my neighbour, that when it happens there is no sale for these things at Spitalfields Market that the waggons should be drawn into the poorest localities, say Bethnal Green or Whitechapel, and sold to the very poor at almost a nominal price; his answer is, they would not buy—scarcely have them at a gift. The buyers of greens from the costers are the better sort of people—mechanics, small shop and housekeepers. The lower labouring class will not buy or take the trouble to cook them if given.

If "WILTSHIRE RECTOR" could prevail upon these people to use them he would be doing them a service for their health and pockets' sake, and would benefit the grower, who, after having expended his time, his money, his experience in getting a crop, is unable to dispose of them even at a ruinous sacrifice.—W. P. B.

[We can confirm what our correspondent has stated so well. Many acres of vegetables are rotting in the fields, and the loss to the cultivators must be very serious.—EDS.]

#### THE CHRYSANTHEMUM FOR COUNTRY GARDENS.

I HAVE seen it repeatedly stated that the Chrysanthemum is essentially a town plant, a plant for the middle classes, but one which would not be tolerated by the gentry and nobility in their country gardens. Near to large centres of population Chrysanthemums have been cultivated in many small gardens and grown to great excellence, whereas in large country gardens, where many things press on the gardener's attention at one time, the plant has been necessarily neglected. Everybody who has grown Chrysanthemums knows how easily they are cultivated, and that any neglect continued for a short period ruins the season's flowering. That is the only reason I can conceive why Chrysanthemums are neglected by country gardeners, for I know by experience that the flower itself is as highly esteemed by employers in the country as it is by those living near towns. A good collection of Chrysanthemums is expensive to grow well. Potting, staking, disbudding, and watering are all important, and they cannot be neglected if success is expected. At the same time, as a country gardener, I am quite certain they well repay all labour bestowed on them; at least such is my experience. With a good collection of well-grown Chrysanthemums and another of Zonal Pelargoniums, and you may have a display which you may well be proud of at the worst season in the year. I never grudge any labour spent on either of these flowers, they repay it so fully.

To those who may be intending to grow Chrysanthemums in the coming year the following hints may be useful in selecting varieties. Do not grow too many of one section, but obtain the best of each. Some people prefer incurved flowers, others Japanese, and others, again, admire the Anemone varieties. If many cut flowers are required include the varieties best fitted for that purpose. Good varieties for cutting are also amongst the finest in their sections. The following list includes most of the best:—Large-flowering Incurved—Mrs. G. Rundle, Mrs. Dixon, Mr. G. Glenny, Jardin des Plantes, Mr. Brunlees, Empress of India, Venus, White Venus, Prince of Wales, Lord Derby, Pink Perfection, Mrs. W. Shipman, General Bainbridge, Mrs. Sharpe, Her Majesty, Antonelli, Lady Slade, Lady Hardinge, Prince Alfred, Bella Donna, Beverley, Golden Beverley, Princess of Wales, and Princess Teck. Of the reflexed flowers the following are well worth growing:—Dr. Sharpe, Progne, Julie Lagravère, Beauté du Nord, Christine, and Annie Salter. A few of the large-flowering Anemone varieties should also be grown. Of these, Fleur de Marie, Lady Margaret, Mrs. Pethers, Gluck, Empress, and Louis Bonamy are excellent. A good selection of Japanese is the following:—James Salter, Elaine, Fair Maid of Guernsey, Oracle, To Kio, Peter the Great, Madame Godillot, Ethel, Fulton, The Sultan

Sarnia, Gloire de Toulouse, Fulgore, La Nympe, Madame Lemoine, Bouquet Fait, Hero of Magdala, Dr. Masters, and Grandiflora, Erecta superba. Amongst the Pompons a few of those known as Anemone Pompons should be grown; these are very useful for cutting. Some of the best are Madame Montels, Marie Stuart, Jean Hachette, Antonius, Dick Turpin, and Perle. Of the ordinary Pompons the most suitable are Cedo Nulli, Mdle. Marthe, President, Golden Circle, Bob, and Bijou de l'Horticulture. Besides these I intend to have many early-flowering varieties both out of doors for border decoration and in pots for flowering in October. Little Bob, Madame Peceval, Fred Pélé, l'écocité, Illustration, and a pure white one, of which I do not know the name, are distinct and good. These are enough to begin with.

In commencing the cultivation of the Chrysanthemum I would advise purchasing the stock as cuttings. Order from three to six cuttings of each variety in the large-flowering and Japanese sections; the Pompons according to the number you may require to grow. The cost will be merely nominal, and every cutting is, under ordinarily good treatment, sure to root. I prefer placing the cuttings in sufficient heat for them to require regular watering, which consequently induces quick rooting; after roots are formed the young plants are better kept cool. We propagate a large number of a few good varieties for the production of flowers; they are struck in March, and after being rooted are placed on ashes in a cold frame until planted out in the kitchen garden, where they remain until October. The cuttings for culture in pots should be placed singly in small pots. At the beginning of April shift the plants into 5-inch pots and keep them cool. The plants will thrive well in these pots until they are finally potted in the beginning or middle of June. They will, however, require liquid manure to render them healthy and vigorous. I tried various sizes of pots this past season, and have found three plants in a pot 13 inches in diameter are the most satisfactory in foliage and blooms. The large pots are also easier to manage with respect to supplying water.

The Chrysanthemum will grow in almost any soil, but I prefer a strong loam with a third of manure composed of equal parts of cow and horse dung rubbed down fine; soot and bone dust may also be added. Good drainage is required for large pots, and the soil cannot be rendered too firm. It must be remembered that the firmer the soil is the finer will be the roots, and the better the quality of the blooms. When the whole plants are in their flowering pots arrange them in a position that is not too sunny; place stakes to each growth, and tie loosely. I am not particular about rubbing off side growths, as they furnish us with a good supply of flowers for cutting. As the soil is filled with roots supply liquid manure every time the plants require it. Watch for the terminal bud, and rub off all with the exception of that one. From the middle to the end of October the plants must be housed. The chief point to keep in view is to keep the buds near the glass; when they have opened the plants can be arranged for effect. The only enemies the Chrysanthemum has to contend with are a species of aphid that may be destroyed by repeated applications of tobacco powder, and a maggot which some seasons is very destructive, but may be killed by squeezing it between the finger and thumb. Towards autumn mildew attacks the foliage; slight dustings of sulphur is the antidote for this.

Pompons require pinching about three times, and the shoots tied out: with a few stakes these make very useful decorative plants for conservatories. Most of our plants have been stripped for church decorations, but we have dozens of plants of Fair Maid of Guernsey which have not yet opened a bloom, besides numbers of Julie Lagravère and others now at their best. These were all planted out in the kitchen garden, lifted in October, and placed in a cool well-ventilated house, where they have received abundance of water at the roots.—R. P. BROTHERSTON.

### MUSHROOMS.

It will be admitted that the successful growth of Mushrooms is an accidental circumstance with most people. Why this is so I shall not stop now to inquire, but it will be readily understood by many who are interested in their culture. We rarely see them in the market or in the shops unless it be during the short season that they are found in the meadows and pastures—their natural home; and here its uncertainty is made manifest, for while in one autumnal period they are declared to be in plenty, another there is none, and in many pastures they may at all times be looked for in vain. I am led to these remarks by having seen so recently as Friday, the 24th December, some really fine solid Mushrooms growing in the open air—that is, with no other protection than some small handglasses afford, and with an old piece of mat thrown over these when the Mushrooms appear.

My neighbour's garden has a large mound of scoria from the furnaces of his mills, which has accumulated until it is now several feet high; in front of this on the sunny side is a narrow uneven strip of ground not more than a land yard in extent. It was well manured and broken up in the springtime, salading was grown there afterwards, and then the same plot of ground was planted with Veitch's Giant Cauliflower, and which speedily grew to a large size. Before the planting of these Cauliflowers, however, it is right to say, my friend said he had by him probably a bushel of Mushroom spawn which had been lying by unused for perhaps three years. He broke this up, scattered it upon the ground. It was then pointed in with a digging fork; the Cauliflowers were planted, and before these were cleared from the ground Mushrooms began to appear, and have continued so to do with more or less abundance to this hour. A few days ago my neighbour said to me, "I have taken to Exeter again this morning another fine lot of Mushrooms, and there are more coming now."

From this small spot of ground, and by this means, he has gathered considerably over half a hundredweight of prime Mushrooms, and latterly, as is well known, their value ranks high—1s. per lb., to put it at a low average quotation; some idea, therefore, of his success may be easily gained.—JAMES ENSTONE, *Wear, near Exeter.*

SOME time ago I read an inquiry in the Journal as to how Mushrooms can be established in pastures, and in reference to that the following remarks may not be devoid of interest. One field here has this year produced such great numbers of Mushrooms, and so many people came to gather them early in the morning, that the farmer had to stop the practice, as the Oats were greatly injured. This abundance was attributed to salt having been strewn over the land with the corn, which seems all that is required here to induce the growth of Mushrooms. I have seen salt strewn on meadow land with the same result, especially where cattle graze. About Lent seems the best time to strew it over pastures. The manure of cattle greatly increases the number of the Mushrooms, but I cannot understand their appearing in a field where only a slight dressing of manure was placed as usually used by farmers for killing wireworms. I have seen the same result when Saintfoin that had been down nine or ten years was broken up, salt being employed for fear of wireworm. I would advise gardeners to try the experiment in parks where cattle are kept. Perhaps some of your able contributors can enlighten us as to Mushrooms coming on arable lands where they have not been seen for years, and where no manure has been placed.—HENRY GALTON.

P.S.—I intend to try salt round our clumps next year.

I WISH to add my testimony to that of Mr. Thomson as to the value of sawdust for a propagating and plunging material. Palms and other stove plants plunged in it soon root-out and enjoy it. I wish also to state another valuable use we make of it. Sawdust about here has for several years been very much employed as bedding for horses. Two years ago I found in the manure from such bedding after lying in a heap a short time, what appeared a good Mushroom spawn; and as we had difficulty in procuring sufficient droppings for making Mushroom beds, I determined to try a bed of sawdust manure, and fully made up my mind for a good crop of bad fungus, but to my agreeable surprise it turned out the best bed of Mushrooms that we have had for years. Since then I have used nothing else when I wish to make up a bed. I have the manure fresh, make the lower part of the bed, then screen part of the sawdust out of the remainder of the manure, and add about 2 inches of the screened droppings on the top of the bed, make it thoroughly firm, then insert the spawn, soil it over, smooth the surface with the back of a spade, and in a month or five weeks I have a fine crop of strong brown-capped Mushrooms. I had insufficient spawn last spring, and after making a bed neglected to spawn it, as we had such a large crop on hand. In a few weeks the Mushrooms began appearing; I then soiled it over, and had as large a crop from that bed as any of the others, but of a smaller size. Possibly the above information will be of some service to your readers.—JOHN WOOLLAM.

AUSTRALIAN WILD FLOWERS.—The *Sydney Morning Herald* of November 4th, says:—"Miss Marianne North, who came to these colonies to paint specimens of Australian wild flowers, has, so far as this colony is concerned, completed the agreeable task which her combined admiration for nature and art constrained her to execute. During her stay Miss North travelled through the district of Illawarra, visited Camden Park, and also the residences of several families in the Blue Mountains and other

localities, painting as opportunities permitted her the distinctive flowers which she not only met with on the ordinary thoroughfares, but explored hills and valleys in quest of. The lady does not intend the boundaries of Australia to circumscribe her present intentions. Her desire is to paint, as far as is possible, the wild flowers of the world, and she has now proceeded to Victoria to secure for it that furtherance which her devotion to her task is likely to acquire.'

#### SELECTION OF VEGETABLES.

FOR the information of the correspondent who writes under this heading at page 30, I may state that I placed Giant White Runner Bean, Shorthorn Carrot, Wheeler's Tom Thumb Lettuce, William I. Pea, and Green Gage Tomato, first of their respective kinds, because I could answer from experience as to their merits in the majority of cases. To make matters more simple for your correspondent, I may say Giant White Runner Beans when used in that tender state when the pods are nearly full grown, but the beans hardly formed, are as green as desirable when cooked. Shorthorn Carrot is more suitable for all soils and situations than any other variety, as it comes more quickly to maturity and does not require such a depth of soil as the long varieties. A hundred plants of Wheeler's Tom Thumb Lettuce may be grown either in frames or out of doors at any time of the year in the same space as would be required for three dozen of the ordinary Cos varieties, and its little heads will be found more serviceable and high-flavoured than any other that can be grown in the same time or space of ground. A Pea like William I. that will come in very early and may be had very late can hardly fail to be a good useful Pea for anyone only growing one variety. Better could be named for particular times, especially for midseason, but considering the season from first to last this Pea could not fail to give satisfaction. Carter's Green Gage Tomato is a general favourite with all who have grown it on account of its prolific habit and rich flavour. Your correspondent has evidently doubts about the Custard Marrow, but as I and many others have proved, it is free-bearing and of very fine flavour.—J. MUIR.

#### THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 546, last vol.)

HOW PLANTS GROW.—It has always been an unsettled point as to the precise manner in which liquid sap becomes converted into the more solid fibres and tissues of the plant's structure. The common belief has been that the sap undergoes some kind of elaboration within the leaves, and is then passed back again to commingle with other sap in the stems and branches, by which it is precipitated as a deposit. For such credence there is, however, not the slightest support, for no downward trace of the sap has ever yet been detected, nor would such a proceeding be possible without inverting the natural order of the existing arrangements; but, on the other hand, there is the most indisputable evidence possible, as confirmed by the preceding experiment, that by electrochemical deposition an albuminous fluid can be consolidated into a transparent gelatinous substance, and to those who are conversant with the principle of the "electrotype" or the production of metallic castings, precipitated by electricity from a solution of the metallic oxide, the identity of the two processes will be readily apparent. In the one case the metal is made soluble by being combined with oxygen, and in this liquid state it is placed in contact with a conducting mould, when by withdrawing the oxygen it is again made insoluble, and becomes deposited as a bright reguline metal, taking the exact form of the surface to which it is thus made to adhere. In the other case carbon takes the place of the metal, and by being combined with oxygen it also is rendered soluble, and constitutes the basis of all albuminous compounds. In figures 96 and 97 on page 547 of the last volume this fluid albumen, consisting of "white of eggs," is represented as having formed around the positive electrode (F) only a loose frothy mass, whilst around the negative electrode (E), which indicates the growing condition, it has assumed a specific form—a hollow and somewhat globular ball of jelly-like consistence, attached to which, as a tangent to the central part of the outer surface, springs the diaphragm (C G), which is brought into existence to separate the opposite electrical conditions of the two portions of the electrolysed albumen. On the same principle as the production of this diaphragm by the "deflexion" of force we have a very common but perfectly similar result occurring in our ordinary fishtail gas burners—two oblique jets of gas issuing from cylindrical passages strike together, by which they are then spread out into a flat flame transversely to their own direction, just in the same manner as in the above experiment.

By analysing the structure of a common fowl's egg in conjunction with the preceding phenomena, it affords us a far better opportunity of understanding that which takes place on a more diminutive scale among the cells of plants than, from their minuteness, could possibly be derived from these microscopic formations themselves. Thus, supposing the negative electrode (E) to be surrounded by a ring of positive electrodes in such manner that the force would be converging to the negative centre from all directions, the transverse diaphragm would then necessarily become curved, so as to form an entire bag or envelope around it, just as it occurs in the egg, the shell being lined with a watertight membrane closely adherent to its inner surface. With regard to the shell itself; this, too, is equally represented. Instead of the white of egg in figs. 96 and 97 let some plain water with a few grains of common table salt or a few drops of dilute sulphuric acid be introduced, and the lime out of the ivory (G) under the positive electrode (F) will then be taken up and carried away to the negative electrode (E), upon which it will crystallise, forming a whitish encrustation; but with the white of egg the viscosity of the latter causes the lime to be arrested at the central diaphragm (C G), and there to form a layer of globular lime crystals identical with such as are seen in the hardening shells of crustaceans, such as shrimps, crabs, &c. Within the egg and floating in the albumen is another bag containing the yolk, which is the immediate nidus of the embryo chick. But should this second bag by any accident become ruptured so as to suffer the different contents to mix together, it would be good-bye to all chance of a chicken.

From this it is seen to be evident that it is the relative position which is all-important, and not merely the presence of certain compounds irrespective of their relative places. To secure the contents of the egg from the risk of such injury a most beautiful provision is made, which does not appear to be rightly appreciated. It is generally imagined that the vesicle of air contained at one end of the egg is intended as some sort of temporary sustenance for the bird before it leaves the shell; but this is a mere figment. Its real use is to act as an elastic spring to maintain the contents of the egg as always filling the interior, so as to avoid shaking. Were this air absent and the egg full when cold, the warmth of the bird would cause it to expand and burst the shell, like water-pipes, by the frost; but as air is compressible, although liquids are not, the air shrinks in bulk to make room for it, and then expands again whenever the contraction of the liquid may follow. This same principle has been adopted to prevent water-pipes, casks, &c., from being burst by the frost. In the case of the former a very small indiarubber tube, tightly closed at both ends, is inserted along the interior wherever it may be liable to become frozen; but in the latter an uncorked empty champagne bottle is floated, neck downwards, in the centre of the jar or cask, and retained there either by being tethered to a brick or fastened to a stake placed diagonally across from top to bottom.

Now, as the developing chick requires a supply of carbon out of which to form its flesh, feathers, and bones, &c., we find this supply stored up in the surrounding albumen—the white, in which it floats, and which disappears in proportion as the bulk of the bird increases. But this albumen is also the main food of plants. It has been generally asserted that vegetation derives its entire supply of carbon from the carbonic acid contained in the atmosphere. That, however, is a sweeping assertion that seems quite inconsistent with known facts. One of the richest manures that can be applied to plants is bullocks' blood, the serum constituting the greater part of which is albumen. All animal and vegetable material is also composed of albuminous compounds rich in carbon; and as these constitute the food of plants, it can only be by furnishing them with a carbon compound they can readily and rapidly appropriate.—W. K. BRIDGMAN, *Norwich*.

(To be continued.)

#### SENECIO SPECIOSUS.

THOUGH not a novelty in the strict sense of the word, it is only recently that general attention has been directed to this plant; and as from its attractiveness it is likely to become a favourite both for indoor and outdoor decoration, a few remarks upon the history connected with the species and the ornamental value of the plant may not be devoid of interest.

First, regarding the native country of the plant there has been great confusion, for China, Mauritius, and South Africa have each been assigned as the portion of the globe whence it was first obtained. However, the claims of the last-named continent have now been fully established, and it is probable that if plants had been sent to England from China or Mauritius they had been previously introduced there from South Africa. Mr. N. E. Brown of Kew has devoted some attention to the history and synonyms

of species, and with satisfactory results, for the name given above is now accepted as correct, and the plant was figured under it in the "Botanical Magazine" a few months since. Johnson's "Gardener's Dictionary" gives the date of introduction as 1789, but the plant appears to have been cultivated as early as 1732 in Dr. Sherard's famous garden at Eltham; but whether it has continued in this country since that time is uncertain, although figures have appeared at different times in Andrews' "Botanist's Repository," the "Botanical Register," Loddiges' "Botanical Cabinet," and lastly in the "Botanical Magazine" in 1880. It has been described under the names of *S. pseudo-China*, *S. concolor*, and *S. concolor* var. *hispido-scabra*, all of which have been rejected in favour of *S. speciosus* as already stated.

It seems strange that a plant of such merit should have been known for about 150 years without becoming popular, but, like many other old introductions that have now almost disappeared from gardens, it has been long neglected, and the nurserymen are again bringing it into notice. It possesses the recommendation of being half-hardy in England, consequently it deserves a foremost place amongst the plants in the so-called mixed border, where it will flower during the greater part of summer. Grown in pots, too, it forms a valuable and attractive addition to the greenhouse or conservatory, in which positions the flowering period is greatly prolonged. In habit the plant is moderately dwarf and compact, the radical leaves forming a rosette-like tuft round the stem; they are somewhat thick, inversely lance-shaped, the margin being toothed or lobed. The flower stems rise to about a foot in height, and bear numerous flower heads (capitula) of narrow strap-shaped, rich purplish magenta florets, each head measuring about  $1\frac{1}{2}$  inch in diameter, and disposed on the stems in a corymbose manner, and are altogether rather suggestive of the *Cineraria*. However, it is unquestionably a handsome plant, and being of easy culture is worth the attention of all.—L.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 17. NEW SERIES.

THOSE who deal in statistics have, I believe, attempted a half-serious calculation of the quantity of dirt the civilised human being swallows each year in taking his customary meals, even where the cooking arrangements are first-class; and if a computation were possible of the number of insects we dispose of unconsciously, some persons might be more surprised than pleased. At the season of Christmas it is not agreeable to discover that what as first you took for a Plum stone left by accident in your slice of pudding is the carcase of a beetle that had been feeding in one or other of the articles that go to make up that seasonable dish. Probably a good proportion of the insects we eat, or narrowly escape eating, are beetles, as imago or larvæ. The latter, happily, if cooked up often leave no trace, nor have they a flavour usually that would distinguish them from the substance in which they live and feed. In the group of beetles that we now proceed to examine there is one species, *Tenebrio molitor* (fig. 10) we may well regard with an unfriendly eye, as it frequents flour or meal, upon which the uninviting larva feeds, and there hides securely; but it may be consolatory to reflect that mealworms are at least useful to bird-fanciers!

The second group of the beetles that are placed in the section Heteromera, the small middle section of the coleopterous order, are called Atrachelia—that is, "without a neck." The hind part of the head appears as if sunk in the thorax, and the wing-cases are hard, not flexible as in the Trachelia, noticeable readily in the Oil and Cardinal beetles already described. One or two of these species resort to flowers, but the bulk of them haunt dark and damp spots, and gardeners have had at present no reason to complain of this group. One species, however, rejoicing in the appellation of *Melandrya caraboides*, occurs in old Willow trees, larvæ and beetles together, the beetles having this curious habit of living for a short time in the burrows of the larvæ, afterwards taking excursions in the air from tree to tree. They are about two-thirds of an inch in length, with flattened bodies and blackish wing-cases; the larvæ are slender and muscular. It is not a sufficiently common species to do any injury to Willows, compared with such insects as the Musk beetle and the Goat moth. A curious and allied species, only about half the size of the preceding, is *Orehesia undulata*, so named from its power of taking leaps or skips, which seem to be rather objectless, and which are performed by means of the long spines on the hind legs. In colour it is reddish-yellow chequered with black. Their favourite food is moist Boleti growing upon trees in woods or damp places, and Mr. Curtis when hunting them found he could only capture specimens by pushing a net close to the trunks.

Sombre in colour and unattractive in appearance, veritable

"black beetles" are those of the genus *Blaps* (fig. 11) one of which—*B. mortisaga*—has received the ominous name of the Churchyard Beetle. This does, with its congeners, haunt cellars and damp places underground, and so I can quite understand that it may occur in church vaults or catacombs. Both the beetles and their larvæ are harmless to garden produce, though they may sometimes be found in pits; the larvæ are similar in shape to the mealworm, but much larger. It is one of the curiosities of medical science that the larvæ of one species or other of *Blaps* have in several instances been thrown up from the human stomach; how they got there and lived for a time is puzzling. The beetles have such strong vitality that they will revive after being long immersed in spirits of wine. In their movements they are so tardy as to suggest that they suffer from chronic rheumatism! Leaving these we pass to the Tetramera, the third great section of beetles, having the tarsi apparently four-jointed, and containing swarms of species, which naturally break up into three grand divisions. These beetles are commonly diurnal in habit, particularly active, and for the most part feeders upon vegetable substances, though a few are predacious. We have seen, in groups of beetles already noticed, various species that do mischief in gardens, orchards, and fields; we come now upon a multitude of species, often small in size, but highly destructive and difficult to destroy or keep in check. Especially is it so with the long-nosed or beaked beetles, to which belongs the general name of weevil, the Rhyncophora, first division of the Tetramera, and readily distinguishable by the head being always more or less lengthened, the antennæ standing

Fig. 10.—Larva and imago of *Tenebrio molitor*.

Fig. 11.—A cellar beetle (*Blaps obtusa*).

out prominently upon the beak or snout. Though as a group they are thus easily recognised, the species are many of them exceedingly like each other in form, size, and colour. Writing concerning the weevil tribes Mr. Stavelcy aptly remarks—"No part of a plant is secure from the attacks of weevils, for one species devours the green and soft parts of the leaves of fruit trees, another the bark, another the roots. Some destroy the young buds either of leaves or flowers, while others gnaw their way into and deposit their eggs within the setting fruit, which is to remain suspended till the time of transformation, when 'down will come cradle and baby and all,' and the grub, after remaining for a time sheltered in the earth, will return to the daylight in a perfect state. Acorns, nuts, young Plums are easy to find with the little weevil grubs enclosed, while the sheller of Peas can bear willing testimony to their attention to that part of creation. Some roll up leaves, which they have previously severed from a tree, and deposit their eggs therein; others lay them in the ground 'convenient' to the roots which are to form the food of the young when hatched."

Really, as an ancient and reflective gardener remarked, "When you consider what insects and other things one has to be bothered with it's a wonder that one gets flowers and fruit at all." Fortunately, modern science has supplied us with more effective applications for destroying weevils than were known or dreamt of in the days of our grandfathers, but at the best they would fail were it not that we are also helped by the natural enemies of these beetles. Many are killed, moreover, especially in their early stages, by unfavourable weather. That splendid Indian species called the Diamond beetle, as I may note here, belongs to the weevil family, and, placed under a suitable magnifying power, a goodly number of our British weevils that appear unattractive to the naked eye display beautiful tints on the wing-cases, due to the presence of an array of scales with varied colours. As a rule, the beetles of this group go about their work noiselessly, but it has been found that a few of them can make a long chirp by rubbing the wing-cases against the abdomen.

Before referring to some of the numerous weevils that are objects of dislike to the horticulturist with good reason, I shall mention a species which is undeniably a useful one. It is a small insect with antennæ that are tipped with a club-like end composed

of three joints, and in colour it is a rich brown, the extremity of the body only being whitish. Though not as common as we might desire it to be, this weevil, by name *Anthribus albinus*, is to be seen occasionally in gardens and conservatories, where the females seek out the scale (or coccus) of some species or other, upon which they deposit eggs, the larvæ subsisting upon these insects.—J. R. S. C.

#### THE WINTER HAUNTS OF WASPS.

IN your last issue "A KITCHEN GARDENER" asks for information respecting the winter haunts of wasps. Having spent much time collecting and studying insects, I can, perhaps, give him the information he requires. I believe the chief winter quarters of queen wasps are nests in which they were hatched. I have dug many nests out of banks at the commencement of winter, and there have always been two or three queen wasps hibernating in them. But all do not pass the winter in the old nests; I have often found them under the loose bark of trees, amongst fallen leaves, in sheds, and various places, where they lie up in a state of torpor until the warm days of spring awaken them to life. After a fresh bed of leaves has been made up in the forcing houses in winter time, a queen wasp will sometimes be seen flying about, having been carried in with the leaves and awakened out of its torpid state by the warmth of the house.

If "A KITCHEN GARDENER" thinks of destroying wasps in their winter quarters, I am afraid he will not be very successful, as he might hunt for a whole day and not find one; but every one should be hunted and killed when they appear on the wing in spring time, when they are generally sluggish in their flight, and are easily caught. It is better to pay for them than wait until they have established a colony.—A. BARKER, *Hindlip*.

THE last issue of the *BULLETIN DE LA FÉDÉRATION DES SOCIÉTÉS D'HORTICULTURE DE BELGIQUE* contains a number of reports from the various affiliated Societies, with the names of the officials and the number of members in each. A translation is given of a document recounting the particulars of a botanical excursion in Colorado, containing much interesting information respecting the flora of that region. The eighth edition is also included of the "Correspondance Botanique," the very useful work of Professor E. Morren, which is still more extended and improved than former editions. For naturalists having a wide correspondence such a work is indispensable. The last-named is also published separately at No. 1, Boverie, Liege.

— FROM the report of the *ROYAL SOUTHAMPTON HORTICULTURAL SOCIETY* for the past year we learn, that notwithstanding the rather heavy loss of the autumn Show, there is a balance of £98 to the credit of the Society. About one hundred new members have joined the Society, so that the prospect is rather encouraging. It appears Mr. Hinds, gardener to Lord Wimborne, has offered a guinea towards a silver cup to be given for a stand of *Chrysanthemum* blooms at the next autumn Show—an example it is desirable should be followed by other contributors, so as to render the cup creditable to the Society. Mr. Gower of the Tooting Nurseries has also promised a prize value £5 5s.

— "HAVING to place something fresh on the dinner table every evening," observes a correspondent, "on one occasion flowers of *CYPRIPEDIUM INSIGNE* were used with Maidenhair Fern. I had no idea how effective it would appear, and it has now become quite a favourite. I also place about a dozen blooms in a glass with foliage, and it is equally pleasing. I have a hundred blooms of it left on the plants in a cool house, and I fully mean to make the most of these."

— WE learn that Mr. W. IGGULDEN of Orsett Hall, Romford,

has been appointed gardener to the Earl of Cork and Orrery, Marston House, Frome; and Mr. T. RECORD, Sheffield, gardener and bailiff to C. A. Hanbury, Esq., Belmont, East Barnet.

— A WRITER in Case's "Botanical Index" has the following relative to the *USES OF YUCCAS*:—"The bruised root of all the *Yuccas* were formerly used very extensively by all the natives, at least on the Pacific coast, for making a soapsuds in washing, and at the present time it is not an uncommon sight to see the semi-civilised Indian and her Mexican half-sister still using this vegetable soap, which they call 'Amole,' in the Mexican villages, even as far north as Utah. It certainly possesses the economic advantage of always being handy and ready for use on the desert plateaus of the West, while if these indolent people were to depend upon their own exertions for making their supply in the ordinary mode of making soap there would probably be very little used by them."

— "R. H., *Penzance*," observes that *GARRYA ELLIPTICA* is one of the most graceful of evergreen shrubs. Its chief beauty consists in its long catkins, which in winter hang in elegant tassels from the ends of the shoots. It is a hardy evergreen shrub, preferring sandy loam as its soil. It is best propagated by layers in the autumn, which when taken off should be potted and placed in a cold frame to become established. It may be also increased by cuttings under a handglass in sandy soil towards the end of summer.

— THE schedule of the *BRISTOL SPRING SHOW SOCIETY* states that the next Exhibition will be held on March the 23rd and 24th in the Victoria Rooms, Clifton, when, in addition to numerous prizes in the classes, special prizes of a silver cup value four guineas, two guineas and a half, and one guinea and a half, will be offered by the Treasurer, Walter Derham, Esq., for a collection of *Hyacinths* and *Tulips*. The Banksian bronze medal of the Royal Horticultural Society will also be offered for the best twelve *Hyacinths* in any class except Class 1.

— ONE of the latest additions to the Kew collection is the pretty *BEGONIA SOCOTRANA*, a new species from the island of Socotra, where it was found by Dr. I. B. Balfour in his recent explorations. It has roundish peltate leaves and pinkish flowers, with four or six divisions nearly equal in size. A plant flowered last month at Kew, from which, we are informed, a coloured plate for the "Botanical Magazine" has been prepared. We recently observed a specimen in one of the compartments of the new range, which indicated the character of the plant and its probable value for decorative purposes.

— "PRACTITIONER" sends these observations on *INFERIOR CELERY*—"For many years we have been in the habit of raising a quantity of Celery very early in the season to have it of large size for the autumn exhibitions. In changeable seasons many plants run to seed before they are of full size, but others do not, and, as a rule, we always find these to be very inferior in quality and 'pithy' by November or December. Another batch of plants is raised and planted much later—so late, indeed, that many of them are not more than half or three parts grown by November, and it is very rarely that we find a single 'pithy' head in this late batch. When Celery makes rapid growth during the hot weather of August and September it is seldom sound, but when the growth is made in the colder weather of October and November it is always solid."

— A CORRESPONDENT writes—"Complaints are very frequently made about the ridiculous manner in which the *NAMES OF PLANTS* are lengthened in catalogues, and that there are just grounds for such complaints is well shown by the following names from a catalogue selected at random from some dozens. *Antirrhinum majus nanus picturatum*, *Eschscholtzia californica grandi-*

flora carminea, and *Petunia hybrida grandiflora robusta nana flore-pleno*. If nurserymen go on in this way any descriptions of such plants will be superfluous, for the names can be lengthened in proportion to the real or imaginary distinctive qualities."

— FROM a very interesting pamphlet by Mr. Walter Hill on the Queensland timber we extract the subjoined note concerning *ARAUCARIA BIDWILLI*, the Bunya Bunya Pine—"A noble tree inhabiting the scrubs in the district between Brisbane and the Burnett Rivers. In the 20th parallel it grows thickly over a portion of country in extent about thirty miles long and by twelve broad. The wood is not only very strong and good, but it is full of beautiful veins and capable of being polished and worked with the greatest facility. The cones produced on the extreme upper branches, with their apex downwards, are large, measuring 9 to 12 inches in length and 10 inches in diameter. On coming to maturity they readily shed their seeds, which are 2 to 2½ inches long by 1 inch broad, sweet before being perfectly ripe, and after that resemble roasted Chestnuts in taste. In accordance with regulations issued by the Government the tree is not allowed to be cut down by those who are licensed to fell timber on the Crown lands, the fruit being used as food by the aborigines. The trees produce some cones every year, but the principal harvest happens only every three years, when the blacks assemble from all quarters to feast on it. The food seems to have a fattening effect upon them, and they eat large quantities of it, after roasting it at a fire. Contrary to their usual habits they sometimes store up the Bunya nuts, hiding them in a water hole for a month or two. Here they germinate, and become offensive in taste to a white man's palate, but are considered by the blacks to have then acquired an improved flavour. The taste of the Bunya when fresh has been described as something between a Chestnut and a raw Potato."

— MR. A. WOEIKOF of St. Petersburg writes to *Nature*—"I have found LARGE VARIETIES OF BAMBOO cultivated on a great scale in Northern Nippon, where the winter temperature is certainly much colder than in England. The northernmost place where I found them was the vicinity of Yokobori, about 39° 12' N., at a small distance (twenty-five miles) from the west coast. The nearest place to the south where observations were made is Niigata, 37° 55', and to the north Hakodate, 41° 46'. The coldest month has a temperature respectively of 33° 0 and 27° 3 F. Yusawa being situated about 450 feet high, and in the interior, the coldest month there must have not over 30°, and a heavy snowfall is the rule every winter. Again, on descending the dividing ridge between Jukussina and Yonesawa, I first found large Bamboo plantations near the last place, about 1000 feet above sea level, and 37° 55' N. Between here and Niigata the temperature of the coldest month must differ by about 3°, the latter place being situated near the sea. This gives about 30° F. for Yonesawa, or about the same as at Yusawa. Now in Great Britain, the mountainous districts excepted, the mean temperature of the coldest month is nowhere lower than 36°."

— FROM the same source we learn that last year Count d'Amigo established A TEA PLANTATION upon his estates, situated near Messina. The Tea plant is said to thrive perfectly well there, and its leaves are said to be in no wise inferior to those of the Chinese plant. In order to dry them in a rational manner, and to prepare them for export as well as for home consumption, a Chinese expert is to become the manager of the Messina plantations.

— RELATIVE TO VINE CULTURE IN ALGERIA "J. T." sends us the following:—"Some Vine-growers, whose vineyards in the south of France the phylloxera had destroyed, carried their experience to the not dissimilar climate of the South Mediter-

anean shore, and they have been abundantly rewarded. The present acreage devoted to vineyards is 49,385, of which 5,630 acres were planted in 1879, all but 106 acres being the work of the French settlers. The surprise is, not that the natives have done so little, but that the Arabs, to whom wine is prohibited by the Koran, should have overcome their scruples so far as to devote 103 acres to the cultivation of the Grape. The wine produced in the colony increased from 7,255,204 gallons in 1878 to 7,612,000 gallons in 1879; and there is reason to believe that Algerian wines will soon take a good place in the French markets. Those produced in the romantic province of Constantine are said to resemble the Spanish wines, which are now so largely carried across the Pyrenees for blending with and strengthening the lighter wines of France."

#### ASHLEAVED KIDNEY POTATOES.

THIS Potato is second to none when well grown. Some five and twenty years ago I lived in County Down, near a farm on which it was extensively and successfully grown. Henry Harrison, Esq., owner and occupier of the farm, finding that this Potato gave him a more profitable return than any other crop, it was by him cultivated with great care and attention. The farm of Mr. Harrison rests on and overlooks the Bay of Belfast. It was near a good market for early produce. Buyers from Glasgow and a daily boat to that city from Belfast helped the market of the Irish town very much. One year Mr. Harrison himself went to market with the first digging of his early Ashleaved Potatoes, weighing 20 ewt., which were sold on entering the market for £40 to a Glasgow merchant. Mr. Harrison telegraphed to his land steward for a second ton to be dug and sent the same day to the Glasgow boat; and that night Mr. H. returned from market with £80 for 2 tons of his early Potatoes.

On this farm all the leaves of forest trees were gathered to mix with the manure for the Potatoes, as it is well known that decayed leaves containing a large proportion of potash are excellent food for Potatoes. In digging up the crop the largest Potatoes were placed in sacks for market, the second-sized tubers were kept for seed, and the small ones (the chats) were carefully gathered and preserved. The seed tubers were kept out of doors and well greened. In autumn the centre eye in every set became a bud about the size of a Kidney Bean. Great care was taken in handling the sets not to break off a single bud, as the Ashleaf Kidney does not readily produce a second bud. Before frosts came the seed Potatoes were carefully spread on the floors of a very extensive shed just to touch one another, one Potato deep. In this state they were covered with dry decayed leaves, and lay there all the winter. I called once to see them in their winter quarters about the end of February. A few of the most prominent eyes were appearing through the covering of leaves like forced Asparagus, and I found some white roots creeping below. The land in which they were to be planted was deeply ploughed, well wintered and manured. The manager of the farm was in no hurry about planting. He waited till fine weather had warmed the soil slightly. When the planting time came the sets were handled as gently as if they had been eggs, and carried in hand-baskets from the shed to the field. The Potatoes so carefully prepared and planted grew vigorously, yielded large crops, which realised the highest prices at the Belfast market. The Potatoes were hurried into the market while prices were high. If there were more of the second size of Potatoes than were wanted for seed for another year they were sold as seed Potatoes in the autumn. The chats, as I have said, were carefully gathered and kept, and at the proper time planted in land not specially enriched to produce seed Potatoes of the medium size.

Those who grow kidney Potatoes should procure their seed in autumn and preserve them carefully through the winter, and never allow an eye to be rubbed off. What gaps in rows and what disappointments in crops arise from seed bought at seed shops in spring! In planting all Potatoes it should be remembered that the manure does more good above the seed than below it. The roots come from the uprising shoots and burrow amongst the manure.—A. PETTIGREW.

#### THE ROSARIAN'S YEAR BOOK FOR 1881.

THERE are two Rose annuals which many rosarians read with much pleasure and profit—the one sent out by Mr. Wm. Paul, the other the modest little volume edited by the Rev. H. H. D'Ombraim. "The Rosarian's Year Book" (Bemrose & Sons), improves at each

issue. The writers are masters of their subject, and even experienced Rose-growers may learn something from their papers. Mr. George Baker's two articles are particularly suitable. The first one, "On the Effect of Severe Winter on the Unripened Wood of the Rose," is very much a reproduction of this writer's notes on this subject to the *Journal of Horticulture* last spring. His second article, "On the Cultivation of Roses, Especially on their Own Roots," should be carefully read and mastered by every young rosarian. After giving his opinion upon nearly every kind of stock upon which Roses are now worked, he comes to the conclusion that the best mode of growing Roses is upon their own roots. Now some of our great growers say that many Roses do no good on own roots; it would be well then, I think, for the National Rose Society's Committee to make out a list of those kinds which can not only do but thrive better without the support of a foster-parent. Mr. Baker recommends the use of a plant-dibber when planting these cuttings, so that the ground may be rendered even and firm. I must say that I have been more successful when planting them firmly in trenches, in a thickish layer of sharp river sand. I find four out of six grow. I put in last September about seven hundred of these cuttings, and they look exceedingly well.

Mr. B. R. Cant has a few pithy remarks on "Rose Stocks and New Roses." After thirty years' experience he has come to the conclusion that only two kinds of stocks are necessary—for dwarfs on good Rose land the Briar cutting, on lighter land the Manetti. In the autumn 1879 Mr. Cant sent me at my request three hundred of his Briar cuttings, and I budded about two hundred last summer (all that survived of them the cruel winter, owing to my man's neglect). As Mr. Cant says, it is "more certain when budded." That it produces, too, blooms just as good as the seedling Briar I can testify. I have Charles Lefebvre bought in the autumn of 1879 on Manetti, seedling Briar, and Briar cutting stocks, and grew them in parallel rows; but by far the best blooms I cut in colour, form, and substance were from the Briar cutting row. On new Roses Mr. Cant does not say much, but to judge from his few words he, like the parrot of legend, *thinks* a good deal! He fears that English Rose-raisers may, unless they be more careful, eventually deserve the reproach which is so freely and justly thrown at the continental raisers. Mr. Cant is, perhaps, a wee bit too hard here upon his English brothers, and he might, I think, have mentioned four or five more good and distinct English-raised Roses of the last year or two. Does he not respect Mrs. Laxton for instance?

Mr. George Paul tells us in his paper "The Type of Tea Roses to be Encouraged," and good reading it is. What so practical a cultivator says must command attention and respect. However, I do not agree with him in thinking that we especially want deeper red colour among the Teas. A box of Teas is spoilt in my opinion by a June or July Madame Lambard, and was always spoilt by Cheshunt Hybrid. Madame Lambard in September is all very well; and what a grand grower and free bloomer she is, and, for a Tea Rose, hardy! At the end of his paper Mr. Paul writes, "What would be our perfect type of a real Tea Rose? Bushes which have stood unprotected the winter through in bloom on July 1st out of doors, each in its variety covered with fifty or sixty large blooms of the shapes of Alba Rosea, Marie Van Houtte, Catherine Mermet, Madame Falcot, Niphetos, Souvenir d'Elise, and Maréchal Niel, but of all conceivable colours of the rainbow; and this scene to be repeated till the first frosts come to drop the *many* blossoms as they now do the *few* single flowers of our Tea Rose bushes." "A pleasant dream," he says. Yes, but may it be fulfilled!

Mr. J. E. Ewing's article on "Rose-growing in Light, Gravelly, or Sandy Soils," I have read with pleasure, profit, and with "fellow feeling." But when Mr. Ewing (who is very strong on "Don'ts") says, "Don't attempt to grow Roses for exhibition on light soils unless you are prepared to go to considerable expense," I say, Do under certain circumstances and conditions—*e.g.*, Roses on their own roots delight in light rich soil, also Roses on Manetti; and if amateurs would only be economical, after the example of the Chinese, and take care of every bit of every sort of manure, their light soil will soon be rich enough to grow even exhibition blooms.

Mr. Mawley's meteorological notes are fuller and more interesting than ever, and I only hope that Mr. Cranston will be more satisfied than ever with his marvellous success at the Rose shows last year, now that Mr. Mawley has told him the reason of that success.

The other articles in the book are as follows—"The Rose of Poetry," by the Rev. Alan Cheales; "An Amateur's Experiences," by the Rev. H. B. Biron; "The 1880 Election of Tea Roses," by Joseph Hinton, Esq.; "Handy Bandy," by G. P. Hawtrej, Esq.;

"Some Roses in the North Country," by E. R. Whitwell, Esq.; and "Roses in 1880, with Notices of the New Roses of the last Two Years," by the Editor.

It only remains for me to advise every reader of the *Journal* interested in the cultivation of Roses to at once order the book. It is really too good for a shilling.—J. A. W.

### THE FROST.

THE frost during the week has been extremely intense, and in some districts unusually severe. The temperature in London may be seen by our meteorological observations on page 62. The Thames is covered with floating ice. On Tuesday drifting snow and a violent east wind prevailed. The day will long be remembered in London and almost all parts of the country for its extraordinary inclemency. Gardeners during the week have found great difficulty in maintaining the temperature in forcing houses, and all ordinary outdoor work is stopped. We have received letters from various districts giving records of the frost, but in some cases it is difficult to determine whether the readings of the thermometer have been taken or the "degrees of frost" counted. The former is the correct mode, and should be adopted by those who send information on temperatures.

Mr. J. Witherspoon, writing from the county of Durham, observes—"On the evening of the 14th inst. the thermometer registered 6° below zero, Fahr.; the night previous the mercury stood at 11° Fahr.; and the night following (Saturday) at 8°. The fruit trees &c., being partly protected by snow, have not, I think, taken much harm." Mr. B. Cowan, South Shields, states that "snow has fallen at frequent intervals since the 11th inst., and there is now an average depth of 8 inches. The lowest temperature registered was 4° Fahr. on Sunday last." Mr. W. Craig, Lambton Castle Gardens, Durham, writes, "Severe frost commenced here on the 11th inst. and has continued since, the lowest temperature having occurred on the 16th inst., when 7° below zero was registered." Mr. G. R. Allis, Old Warden, Biggleswade, also states "that the frost commenced severely on the 11th inst., snow having fallen, but not in great quantity. On the 13th, 14th, 15th, 16th, and 17th insts. temperatures of 19°, 12°, 11°, 15°, and 8° were respectively registered." "DELTA" writes from Gloucester—"It would be interesting if statements of the temperature in different parts of the country, both in elevated and low situations, were given by correspondents. Here, in a low situation in the Severn Valley, the minimum by a compared thermometer properly placed was on the night of the 14th 9° Fahr., the max. on the 15th 21° Fahr., the min. 7.5° Fahr." Mr. A. F. Barron, of the Royal Horticultural Society's Gardens, Chiswick, states that "the frost is intense; the lowest temperature on Monday night last was 5° Fahr." Mr. W. Taylor, Longleat, writes, "We have registered the following temperatures here:—Saturday morning at 4 feet from ground 4°, and the same on grass; Sunday 11° and 6° on grass; Monday 12°, and 7° on grass." Mr. Thos. Nicol, writing from Fifeshire, observes, "The frost is now more intense here than it has been for many years, but the great depth of snow will serve to protect plants considerably." A correspondent in Ireland states the lowest reading of the thermometer up to Sunday last in Munster was 22°, or 10° below freezing point. In the neighbourhood of London low temperatures have also been recorded; for instance, we learn that in Kent one reading gave zero as the lowest temperature, while a few degrees above that have been registered in Surrey, Middlesex, Essex, and Berkshire. The following low temperatures have also been recently recorded:—At Ludlow, zero; Darlington, 10° below zero; Newcastle, 10°; while at Dundee the temperature has ranged from 9° to 2°. In Orkney it is reported the snow is in some places from 12 to 15 feet in depth. To-day (Wednesday) the temperature has risen considerably; in London the thermometer registering 30°, with drifting snow at intervals.

### SALTWOOD VICARAGE, NEAR HYTHE.

A CHALKY district is not the locality in which to look for what are ordinarily called American plants. The sandy and peaty soils of the Surrey uplands in the neighbourhoods of Ascot and Bagshot are the places with which we naturally associate them. The grand establishments of the Waterers and others are so well known that there is little use in saying anything concerning the luxuriance and beauty which characterise the Kalmias, Azaleas, Rhododendrons, &c., which there flourish so vigorously; but chalk is so distasteful to the whole tribe that it is simply misery to see the lingering decay and death to which they seem doomed wherever chalk exists. I know that they will flourish in strong loam, as I have seen them very luxuriant in such soils, but in chalk lands never. It will therefore probably be a surprise to many of your readers to hear that one of the most charming American gardens that I know of in the south of England is in the very midst of the chalk downs which stretch all through our county; and that within a couple of miles of the Channel, where storms do grow and breezes blow, may be seen a valley most beautifully planted, and whose floral beauties are thoroughly appreciated by the visitors to Folkestone, Hythe, and Sandgate, especially if they happen to be

there in what is an unfashionable time of the year, but withal in many seasons a pleasant one—the month of May—viz., the American valley in the grounds of Saltwood Rectory.

Some years ago the living of Saltwood was held, along with several other very good things, by a dignitary of the Church who came under the lash of Mr. Punch for the nice little pickings he had managed to accumulate. But none of these things in the least moved him. He thought that those who win may laugh, and so he enjoyed the jokes that were passed upon him, and who, amongst other good points in his character—and he had many—was a great lover of his garden. Finding this old apparently disused chalk pit in the grounds attached to the rectory he determined on converting it into a scene of beauty and luxuriance. Being of some extent and depth, and surrounded by some large trees, the situation was eminently favourable for it. At the bottom were two ponds of water, which of course gave greater facilities for forming a picturesque piece of landscape gardening. On this he planted a very large number of Rhododendrons, Azaleas, Camellias, and some choice Conifers. As years went on he added

to these all the newer varieties as they came into the market; and as the plants increased in size he had the pleasure of seeing the place assume an appearance of beauty that well repaid him for the great expense and trouble that he had been put to. At his death the living came to a very excellent man, but one on whom the horticultural mantle had not fallen, and the valley passed into rather a dilapidated state; and those ruthless invaders of all our most sacred rights, the railway companies, added to this, for they brought the branch line from Westenhanger to Hythe close by it, and consequently tapped the springs that supplied the water, and the result has been that the ponds no longer exist—a very great deterioration of its beauty.

The living has now passed into the hands of a most excellent and thorough-going horticulturist, Canon Hodgson, formerly Vicar of Croydon, where in the vicarage garden he had been able to show how in a limited space the most varied aspects of horticulture could be presented. In fruit and flowers, both indoor and out, he had achieved great success. Of course when he came to Saltwood the Rhododendron valley became the object of special care and

Fig. 12.—THE AMERICAN GARDEN AT SALTWOOD.

attention, and it has once more, save the water, assumed its former appearance. He has, however, felt that, as owing to the increase of inhabitants in the neighbouring watering places and their desire to see its beauties, it became a considerable tax on him, he has very wisely made a charge for admission, all of which, and a good deal more, is expended on keeping it up.

It would be useless to attempt a detailed description of the various trees and shrubs that fill up this very beautiful spot. The accompanying sketch, taken from a photograph, will give a good idea of one portion of it, but its beauties are too many to be shown in one drawing, or indeed many. Here you will meet with Camellias 15 to 20 feet high; Indian Azaleas, *indica alba* forming dense bushes several feet in height; Rhododendrons of all colours growing most luxuriantly; Araucarias and other choice Conifers not as large as one has seen them, but still luxuriant and healthy; the green turf edging the walks well kept; and the whole presenting a scene not easily forgotten.

I am aware that in other places more varied and luxuriant collections of these plants may be seen; but the great charm of this is, in addition to its real intrinsic beauty, that it is found in a

district where it would be least expected, and like an oasis in the desert: therefore the more valuable.—D., *Deal*.

#### SCIENCE IN HORTICULTURE.

THE *Journal of Horticulture* for January 13th contained an article under the above heading, signed "D., *Deal*," and many no doubt began to read it in the hopes of learning something. I did for one, but was more startled than edified by its truly novel argument.

Sir W. Hamilton gives the following definition of science—"A complement of cognitions, having in point of form the character of logical perfection, and in point of matter the character of real truth."

The first paragraph in the article I have mentioned concludes thus—"If science be all that it asserts itself to be, surely by this time we ought to have had something more certain than conflicting statements and fantastic directions as to culture." Will "D., *Deal*," have the goodness to let us know what science has asserted itself to be, when it made the assertion, and to whom?

Then, again, it would be interesting to know according to what logical rule all science is to blame, because some people make "conflicting statements" and give "fantastic directions."

Is it not a pity that one so able to give sound practical advice, well worth reading, should go out of his way to sneer at—what?—not science, but a series of mistakes which he asserts have been made, but which were certainly made by honest seekers after truth? What good is done, or hoped to be done, by the attempt? I pause for a reply. Let me urge "D., Deal," when next under the influence of the *cacoëthes scribendi*, to remember the concluding sentences of his own remarkable article—"A little weighing and waiting will do no harm now-a-days." Had "D., Deal," weighed the meaning of the word science, or waited until he had refreshed his memory by obtaining a correct definition of it from any standard dictionary, he would never have had his latest effusion put into print—at least I hope not.—F. R. B. S.

#### FINE SUMMERS AND SEVERE WINTERS.

UNDER the heading of "Twenty Years' Temperature" Mr. Plant published in the *Times* of the 4th inst. a weather survey of the last twenty years. It contained some statements which seemed to me surprising; for instance, Mr. Plant says that we have only had three severe winters since that of 1860—viz., 1870-71, 1878-79, 1879-80. It is strange he should have overlooked the very severe winter of 1866-67, when the thermometer was reported as registering 2° below zero in some parts of the country, and I think even a greater degree of cold than this in the midlands. Practically I do not think there was much to choose between 1860-61 and 1866-67. The next severe winter was that began on Christmas day, 1869, and lasted into April, 1870, and followed by the beautiful spring and grand summer of the latter year. It is strange that Mr. Plant should overlook these two long and hard winters.

Then as to the summers. Mr. Plant says we have had but four dry hot summers during the last twenty years, enumerating them as 1863, 1864, 1868, 1870. Now 1863 may be fairly classed among the fine summers, though I think it was more remarkable for its long, dry, and warm spring; but surely the summer of 1864 is out of place in the list. I should have expected the really fine dry hot summers of the last twenty years to be classed as 1863, 1865, 1868, 1869, and 1870; those of 1865, 1868, and 1870 being the three grand seasons. Mr. Plant, however, omits 1865 (the first great summer since 1859) and 1869 altogether in his list of fine summers, though he mentions the April and September of the former year as warm. The April was indeed remarkable for its almost midsummer heat. We have had nothing like it since in that month.

Among the cold Mays Mr. Plant omits any mention of the phenomenal weather of that month in 1873 and 1874—cold biting winds in each year, with the thermometer registering as much as 10° and 12° below the freezing point at night. I write entirely from memory, and should therefore esteem it a favour if any of your readers would kindly say whether I am right in my grouping of the fine summers and hard winters of the last twenty years.—M. R.

#### PETTIGREW'S CARDIFF CASTLE CUCUMBER.

"AMATEUR" writes referring to this Cucumber (page 29), "As it is new to me, I should be glad to know what are its chief recommendations, and in what way it differs from Telegraph or any other well-known kind? Is it a distinct cross, or is it only one of our old varieties under another name?"

It seems strange that "AMATEUR" should single out this particular Cucumber from the many that are advertised for the first time in the trade catalogue he refers to. He admits, however, that "it is new to him," and no one will, I am sure, doubt his veracity. It is a distinct cross, and not "one of our old varieties under another name."

If "AMATEUR" will give me his name and address I shall have much pleasure in sending him a brace of this Cucumber in due time for him to say "how it differs from Telegraph or any other well-known leading kind."

The Editor of the *Journal of Horticulture* saw the Cucumber in question growing here last summer and admired it very much.—A. PETTIGREW, *Castle Gardens, Cardiff*.

I BEG to be allowed to inform "AMATEUR" (page 29 of the *Journal*) that, having had many opportunities of seeing Pettigrew's Cardiff Castle Cucumber, I can assure him it is not an old friend under a new name but a distinct variety, the result of a cross between Hedsor Prolific and Telegraph, and I have no

hesitation in pronouncing it to be the best all-the-year-round Cucumber I have seen. Several gardeners in this neighbourhood can corroborate me in this, who like myself have during the last two years seen it growing at Cardiff, and who have anxiously waited for its being sent out.—THOS. CHAPMAN, *Cardiff*.

IN your issue of the 13th inst. "AMATEUR" writes for information regarding this valuable Cucumber. He says that it is new to him, and that he would like to know if it differs from Telegraph or any other leading variety. About four years ago I sent Mr. Pettigrew a few seeds of a good old variety named Hedsor Prolific, which he grew the following summer with Telegraph, and from a cross between these two varieties the Cucumber in question was raised. I had the pleasure of seeing the three varieties growing at Cardiff Castle last summer, and no one who has seen them could fail to notice the superiority of the new variety. I can fully endorse the recommendation given in the trade catalogues.—JOHN LINDSAY, *Ditton Park, Slough, Bucks.*

NOTICING in "Notes and Gleanings," on page 29, "AMATEUR'S" inquiry relative to Pettigrew's Cardiff Castle Cucumber, and having frequently seen it growing during the last two years, I am glad to be able to give your correspondent the information desired.

The Cucumber in question is the result of a cross between Hedsor Prolific—a good old variety raised at Hedsor, the seat of Lord Boston—and Telegraph, and is quite distinct from each variety. The plant is of moderately strong growth with medium-sized foliage; it bears large crops of fruit, and is equally valuable either as a main crop or in winter. The fruits are of medium size, rather more corrugated than Telegraph, have white spines thinly distributed, and have no neck during the greater part of the season and very little during the winter months. I consider it to be the ideal of a good Cucumber for a gentleman's table, but perhaps is not sufficiently large for an exhibiting amateur.—R. CROSSLING, *St. Fagan's Castle*.

#### KITCHEN GARDEN.

POTATOES where pitted or placed together in quantity will require spreading out thinly as room will permit. This applies especially to all early varieties, particularly early kidney varieties, which if once disbudded seldom grow again so freely as at first, often becoming blind to the serious deterioration of the crop. Onions in reeves will, if kept in a close room or cellar, be commencing to grow, and should be removed to an open airy shed or a covered passage open to the north, as no moderate amount of cold injures them provided they are kept dry. Lettuces during severe frost are raised and left with the roots greatly disturbed; they should have immediate attention after a thaw, pressing the soil firmly around them. An early sowing of Peas should be made in strips of turf or in 3-inch pots three parts filled with light soil, placing about a dozen peas in each, covering with light soil, and arranging the pots in an early Peach house until the seedlings are about 2 inches high, then removing to cooler quarters and gradually hardening them off preparatory to planting out on south borders. Early Mazagan Beans may also be similarly treated, placing four in a 4-inch pot; and if planted out about 2 feet apart on a south border as soon as safe, they will come in early. Seville and Leviathan, if required early for exhibition purposes, will answer the same way. As soon as the weather is favourable sow early and second early Peas in deeply trenched well-manured ground, also Broad Beans.

*Forcing Department.*—At intervals of a fortnight or three weeks introduce roots of Rhubarb and Seakale to the Mushroom house, so as to maintain the succession unbroken. Another bed should be prepared for Asparagus, placing the roots there when the heat is suitable—i.e., bottom heat 70° to 75°, or 80° at the commencement, placing about a couple of inches of fine rich soil on the bed, upon which arrange the roots closely together, and cover 2 inches

deep with light soil. If blanched heads are required cover with 4 inches of cocoa-nut fibre refuse, sifted spent tan, or leaf soil, and when the shoots are 2 inches through that they will have blanched stems with green tops, sufficient light being admitted to effect this, with ventilation to prevent them being weak. Sow Tomato seed, Vick's Criterion being one of the best for early culture in pots. To save time sow three seeds in a 3-inch pot, half fill the pots with soil, and when the seedlings have grown a little remove all but one in each pot; place more soil around the one retained, and keep them near the glass to ensure sturdy growth. Potatoes should be planted on prepared beds when the shoots are an inch or two long, and those advanced in growth will need supplying with tepid water. Earth them up when sufficiently grown, ventilate whenever the weather is favourable, and afford protection in severe weather. Carrots, Radishes, and Lettuces sown as recommended should, as soon as they have germinated, have free ventilation on all favourable occasions. This is necessary until the rough leaves are formed, for if drawn so as to have long stems below the seed leaves they are worthless, especially Carrots and Radishes. Sow French Beans in pits or in pots, eight seeds in a 9-inch pot three parts filled with light rich soil. When the young plants are advancing they need a light position, earthing-up when sufficiently advanced, and maintaining a temperature of 60° to 65°. A good supply of Mint should be placed in pots or boxes in a vinery or Peach house, also a few roots of Tarragon.

#### FRUIT HOUSES.

*Pines*.—Plants that completed their growth early last autumn were rested, and then subjected to an increase of bottom and top heat early in December, will now be showing fruit, and they may be pushed on more rapidly by taking advantage of favourable weather to give them increased heat in the daytime, the temperature being allowed to rise to 80° before giving air, and under such conditions it should be maintained at 85° to 90°, closing the house between 80° and 85°. This will greatly assist the flowers and ensure the symmetry of the fruit. Advance the night temperature to 70° and 75° by day artificially unless the weather be dull and cold, when 5° less will be more suitable. The moisture will need to be proportionately increased, but do not damp the pipes when very hot, nor syringe the plants overhead. The bottom heat should be kept regular at 85° to 90°. Examine the plants once a week, and give tepid liquid manure to such as require it. The temperature for fruiting plants should be 65° to 70° at night, with a rise of 5° by day, keeping the atmosphere moist by damping the paths and walls; where the fruit is becoming coloured water must not be supplied. Succession plants require 60° at night, and 5° more by day. Collect leaves for fresh beds, or provide the requisite quantity of new tan.

#### PLANT HOUSES.

*Stove*.—Plants of *Anthurium Schertzerianum* that have completed their growth should be allowed to rest, lessening the supplies of water, and keep them in a house with a temperature of 50° to 55° for the next six or eight weeks. A few *Achimenes* and *Gloxinias* now potted and started will provide a useful and early supply of flowers; when they commence growing place them near the glass. Tuberous *Begonias* that have completed an early growth may be now started and grown on shelves near the glass, and will afford an effective early display of flowers. Well-grown specimens in 6-inch pots are handsome table plants, especially the brightly coloured varieties. A few *Amaryllises* in heat, and encouraged if possible with a little bottom heat, will come in at a time when they will be useful for cutting or decoration. *Aphelandra cristata*, *A. nitens*, and *A. aurantiaca* Roetzli should have a light position, which will heighten the colour of the flowers, similar remarks applying to *Begonias*, *Epiphyllums*, *Euphorbia jacquiniæflora*, *Gesneras*, and winter-flowering plants generally. *Imantophyllum miniatum* should also be in a light position, and must not have too much moisture on the foliage, or the scapes will decay or be seriously disfigured. *Hoya bella* is one of the choicest of plants for affording buttonhole bouquets and for growing in baskets. It is impatient of stagnant moisture at the roots, and should have a position near the glass.

*Gardenias* that completed a growth early and have been rested awhile will now have their flower buds fast swelling. Assist the

plants with a little extra heat and moisture and weak tepid liquid manure. Young plants not infrequently push fresh growths at the time the buds are swelling, which should not be discouraged, as the growths now made set buds and flower later in the season. By having plants in different stages and introducing them to heat as required a succession of flowers may be had all the year round. *Eucharises* which flowered at Christmas should be encouraged to make a strong growth by maintaining a moist atmosphere and supplying weak liquid manure copiously to the roots. When the growth is complete a drier condition at the roots with a lower temperature will induce rest, but water must not be withheld so as to cause flagging, as it exhausts the bulbs. After six to eight weeks of rest a return to heat and moisture will soon cause the flower-scapes to be produced. After flowering is a good time to divide the plants, potting single bulbs in 6-inch pots, five in a 9-inch pot, and so on, employing turfy loam moderately firm, and burying the bulbs entirely.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

*Pruning Fruit Trees*.—Where the pruning is not completed it must no longer be delayed. All standard trees should have their branches thinned out if at all crowded, taking out those with an inward tendency, or that are interlacing, but do not shorten those retained. Those that are weakly, or have not long been planted, may be cut back freely to induce the formation of the requisite strong head. Pyramids should have all lateral growth spurred-in to within two or three joints of the main branches, unless required to fill-up blank spaces, and the leading side shoots can be stopped to within three or four joints according to the strength of growth. The central leading shoot, if strong, may be left 9 inches or more in length. Many amateurs scarcely realise the fact that weakly growth should be pruned hard to induce better growth, the opposite being the case with coarse growth, which if pruned closely is followed by still grosser wood. If miniature trees are required, close pruning accompanied with root-pruning in all cases where the trees are vigorous must be resorted to; but if a heavy crop is desired let the pyramids from the time of planting grow naturally. Most kinds, and the Pear especially, will retain their pyramidal form, and will be in full bearing with little trouble in the way of thinning. Established trees that have been repeatedly pruned but are not fruitful, if thinned-out where crowded but otherwise left unpruned, will frequently without root-pruning form a number of fruit buds on the retained growth for the following season's crop. Root-pruning will not do more than this, though many writers convey the idea that it affects the current year's crop.

All horizontal or fan-shaped Pear, Plum, Cherry, Apple, or Apricot trees should be pruned and nailed-in or retied as the case may be, taking care to loosen all tight shreds or ties. Morello Cherries should be thinned only, these fruiting on the young growth. The leading branches of the others to be shortened where weak, the central or main branch of partly furnished trees being cut back to within one or two joints, where two side shoots should be laid-in, still continuing the central shoot. Spur-back all laterals and foreright shoots to about three joints of the main branches, to induce the formation of clusters of fruit buds. Peaches and Nectarines should not yet be pruned, the object being to retard the blooming period. Properly furnished bushes of Red and White Currants should have all side shoots closely spurred-in, and the leading shoots shortened to near their last starting points.

Black Currants and Gooseberries produce their fruit principally on the young growths, which only require to be thinned out; and they should also be shortened back occasionally to keep the bushes in shape. Where, however, bulfinches and sparrows are troublesome, it is advisable to defer pruning the Gooseberries till the buds are bursting. Thin out the Raspberry canes and shorten those back considerably, and either tie to stakes or to wires strained for that purpose. Digging about the trees should be avoided in all cases as much as possible, as many of the best roots are destroyed thereby. Hoe over the ground, rake off rubbish, and mulch freely with manure.

*Grape Vines on Open Walls*.—These should be pruned at once, late

pruning causing them to bleed, which is very weakening. Where the main branches are permanent cut back all side shoots to a prominent bud near to the base; young well-ripened canes, however, give the best results, and should be gradually laid-in to replace the old rods. The best system is to train the main rods horizontally near the base of the wall or fence, and take up the fruiting canes at about 15 inches apart, cutting down half of these alternately, and fruiting the remainder, these in their turn being cut down to furnish young canes to follow those obtained from the previous year's pruning. Unripened wood must be cut out, and weak leading canes be shortened back. Old Vines badly infested with mildew should be cut down either to near the ground or to the primary rods, and if before growth commences a deep circular trench be cut about 8 or 9 feet from the stems, and the roots carefully separated from the old soil to within a yard of the stems, then relaid into a good fresh compost of equal parts of turfy loam and fresh garden soil, with a liberal addition of road grit, bone meal, and decayed horse manure, they will be encouraged to push a number of strong canes. From these fresh canes great crops may eventually be taken; mildew, where it may re-appear, being easily kept down by dustings with flowers of sulphur.

*Vines in Houses.*—No time should be lost in completing the pruning of these. Spur-in all laterals to within two joints of the main rods, unless the Vines are unfruitful, as in this case the laterals should be pruned to the lowest prominent bud. Do not allow the young Vines to extend too rapidly, especially if the canes are weak. A strong cane about 2½ or 3 inches in circumference may be left 3 feet in length, medium-sized 2 feet, and weak canes 1 foot in length. Remove all loose bark, especially near the spurs, where only a knife should be used, and give a dressing with some insecticide to destroy any insect pests that lodge in the bark. A mixture of 4 ozs. of soft soap, half a wineglassful of paraffin, and half a pound of flowers of sulphur in a quart of boiling soft water, will be found effective for the purpose and easily procured. The mixture should be kept well stirred and be brushed well into the bark, especially where there are crevices. Inside borders should have much of the old surface soil carefully removed, and a dressing of equal parts of loam and manure applied. Now that it is necessary to use much fire heat care must be taken that the borders do not become dry. If the outside borders have been mulched for the winter this should remain on for a time longer, but uncovered borders ought to receive liberal dressings of partially decayed manure. Prior to this the surface may be lightly stirred with a fork.

## THE BEE-KEEPER.

### SHOULD BEES BE BRANDY BIBBERS?

I PRESUME Mr. Cheshire is a teetotaler; if so he has my sincere respect in doing battle so valiantly against any approach to mimicry among bees of the abominable tippling habits of our people. I think, however, he need be under no apprehension of our bees suffering from this evil. The modicum of spirit which I recommended could not possibly do bees the smallest fraction of injury; and he has certainly conjured up a man of straw for the pleasure of adroitly knocking him down. Moreover, I was not thinking of warming bees by suggesting the use of a small quantity of brandy. It was only as a medicinal improvement that I recommended it at a time when damp and dysentery are the bees' worst enemies. I certainly was not thinking of brandy as assisting in heat-formation or as food. Thanks all the same for Mr. Cheshire's remarks, which I recommend all human tipplers to read attentively.—B. & W.

### NOTES ON BEES IN THE NORTH OF IRELAND.

FOR the assistance of amateurs who wish to practise modern bee-keeping, I will relate how I commenced and how I have succeeded with the valuable aid of this Journal. About five years ago I obtained a good first cast, and kept it two years before I took any honey from it. By that time I had three or four stocks. In the meantime I purchased "Bee-keeping for the Many," where I obtained full details how to make a Woodbury hive. I con-

structed one, and in the following summer I placed the first swarm in it by first hiving it into a straw skep, tilting the Woodbury up 2 inches on a sheet on the ground. I then took the straw skep containing the swarm, placed it quickly on the sheet about 1 foot from the Woodbury, and the bees at once passing into it. This was done about 7 P.M. on the day they swarmed. I knew I must have something as a guide for them to build straight along the bars, otherwise, as I have seen since, they would have built anywhere on the frames. At this time I had never seen comb foundation, but I had plenty of real comb in store, which I cut in strips and secured to the upper bar with melted wax. The bees have done well ever since, and this season I had abundance of honey. In July I took four frames from them full from top to bottom, and in September I took three more, leaving plenty to support them during winter. I had all my honey from the bar-frame by the combination principle—a system I admire, as all the honey I took this season was as pure as it could have been from sectional supers. I took the two end bars in each side of the hive, placed four in their places, and removed them again when filled. If these had been frames with sectional supers the result would have been the same as sections on the top. One of these section frames I saw this autumn, and I am certain the system can be much easier managed than top sections.

To prove this system more fully I had a combination hive made this autumn 2 feet long, 11 inches wide, and 10 inches deep, inside measurement. I have a dummy in the centre in the meantime where I intend to place a queen-excluder, so then the bees will be breeding in one end and storing honey in the other, where I can place whole frames or sections or both. I had my new hive made with the latest improvements, such as zinc slides. The frames are across the entrance—the reverse of the Woodbury. I have a saw mark in each top bar one-eighth of an inch wide, so that I can push the thick comb foundation up through it and wax it on the upper side. It is impossible for the bees to break it off if properly fixed in this way. I have span-roofed covers for all my hives down to the floorboards, and 8 inches on the square above the top, so that I can either super or not. I give them three coats of green paint with varnish, and they are really attractive in the garden.

On the whole last season was only an average one for bees. April, May, and June were cold; July was wet with much wind—so much so, indeed, that many weak bees around here never cast at all. August and a fortnight of September were very fine indeed; in fact, it was all we had for a season. Messrs. Carr and Abbott's (of the British Bee-keepers' Association) visit will do much good I believe, as they created a great interest in modern bee-keeping here, especially in the bar-frame, which was very little known in these parts.—COMBER, Co. Down.

### DORSET BEE-KEEPERS' ASSOCIATION.

THE annual meeting of this useful and growing Association was held on the 11th inst. The chair was taken by the Worshipful the Mayor of Dorchester (W. Durden, Esq.), who was supported by the Rev. H. Everett, Mr. W. H. Dunman, jun., of Troytown (the Honorary Secretary), and Mr. T. Coombs. There were also present the Rev. J. Stanton (Coombe Vicarage), Mr. M. C. Weston, Mr. J. Brown (Maiden Newton), also several ladies, including Mrs. and Miss Brymer, Mrs. H. Everett, Miss Hawkins, and Miss Foster. The Chairman, after stating that the object of the Association was the encouragement, improvement, and the advancement of bee-culture in the county of Dorset, particularly as a source of industry and profit among the cottagers and others in the lower ranks of life, called on the Honorary Secretary to read the report, from which the following is an extract:—

"The Committee have felt great pleasure in presenting their fourth report, because they are able to speak of a considerable increase in the number of members as compared with last year, and to present a satisfactory balance sheet. The exhibition of honey at Weymouth in August last was the best ever held in Dorset, and proved beyond all question that our county offers a fine field for apiculture. One exhibitor sent in 400 lbs. of honey, and another almost as much, the greatest weight taken from a single stock being 89½ lbs. The quality, too, was all that could be desired, and as the greater part of it was in small sectional supers it met with a ready sale. The exhibition stirred up a spirit of inquiry, which resulted in a gain of several members and opened a market that will greatly encourage local bee-keepers. The British Bee-keepers' Association granted a silver medal, a bronze medal, and a certificate for this exhibition. The first-named was won by Mr. W. H. Dunman, jun., of Troytown, and the other two prizes were awarded to Mr. Antell and Mr. Stickland of Puddletown. Efforts have been made to increase the number of cottage bee-keepers by holding manipulations at village shows, for the purpose of illustrating the best methods of depriving bees of their honey without resorting to the old and barbarous plan of suffocation

Several cottagers have already become experts, and some of them have done good service for the Association. Mr. F. Cheshire of Acton, one of the principal bee-masters in England, gave a most interesting and instructive lecture at Dorchester last spring; and Mr. J. Brown of Maiden Newton lectured for us at Cerne in November, when our Secretary and other friends lent valuable assistance. Encouraged by past success, and relying upon the generous support of the principal residents of the county, the Committee have made arrangements for putting forth greater efforts in 1881. Mr. Cheshire has been again engaged to give lectures in several towns, and members of the Association have promised to hold meetings in some of the villages during the winter and spring months. The Committee trust that the members will do their best to increase the number of subscribers by explaining to their friends and neighbours the objects of the Association, which are, first, to introduce a more rational and humane mode of bee-culture amongst all classes of the community who are in a position to keep bees; second, to show them how to obtain the largest quantity of honey, time, and labour; third, to induce the cottagers of the district who have not already embarked in bee-keeping to place stocks in their gardens, so that the myriad flowers which now 'waste their sweetness' may be rifled for the benefit of man."

A satisfactory financial statement was also presented. The report was adopted, and several of the above-named gentlemen addressed the meeting.—(*Blandford & Wimborne Telegram.*)

#### LIGURIAN BEES IN NEW ZEALAND.

I HAVE just received a batch of papers from New Zealand, from an account contained in one of which I learn that the Ligurian bee has only just been introduced into that colony. I enclose a paragraph which is cut from the *Otago Daily Times* of September 18th, and which it would seem appeared originally in the *New Zealand Herald*. Our colonial friends seem to me to put forward some novel claims to superiority on behalf of the Ligurian—viz., that they produce fewer drones, and that the queen lays eggs all the year round. The New Zealander is here as usual rather oversanguine, but may it not be possible that in the fine climate of Auckland the queen might sometimes lay at all seasons? What will our friends here say to the wetted sponge which appears to have secured that cool and moist atmosphere necessary for bees? If breeding was going on in the hives water was no doubt necessary. Did it serve any other useful purpose? Perhaps Mr. Cheshire will kindly explain.—M. H. MATTHEWS.

"Among the many varieties of the honey bee few are held in greater esteem than the Italian variety, or, as it is generally called, the Ligurian bee. They are industrious workers, and delight in honey-gathering. In their hives there are fewer drones than in the hives of the common honey bee, and the queen produces eggs all the year round, though the number is considerably fewer in the winter season than during the warm days of summer. After many failures their successful introduction into America was accomplished several years ago, and since then hives of these workers have been largely multiplied. About the time of the American Centennial Exhibition several attempts were made by Mr. Thomas Russell to introduce them to the province of Auckland, through agents he employed in San Francisco. The first efforts were made by sending queen bees, but the inmates of the several parcels of those that were forwarded all perished before reaching this city. As a last effort a hive was sent forward, but it was evident that there was something still to learn to secure the safe transportation of these bees long distances, for they were nearly all dead before reaching Auckland, and the few sickly ones that reached here died a few days after being landed. The expense of these efforts was borne solely by Mr. Russell, an example very different from the suggestion recently made to the Commission on the Colonial Industries. Nor were Mr. Russell's failures to introduce these bees singular, for Mr. A. Mackay of Brisbane, who made efforts to the same end, at the same time was equally unsuccessful to enrich his adopted land. But while the suggestion was made to the Colonial Industries Commission to spend £500 of public money to send a person home to make an attempt to do that in which so many failures had already been recorded, private and patriotic enterprise was successfully accomplishing that for which State aid was being solicited. Mr. S. C. Farr, Secretary of the Canterbury Acclimatisation Society, had already communicated with R. J. Creighton, formerly of Auckland, and now in San Francisco, on the subject, and Mr. J. H. Harrison of Coromandel had also communicated with his brother, Mr. W. G. Harrison, San Francisco, formerly of Auckland, for the same object. As Mr. Creighton is regarded as the official representative of New Zealand in the City of the Golden Gate, both applications came to be referred to him. He made his arrangements accordingly, and the success which has attended them deserves public recognition on behalf of the colony. Mr. Creighton regarded these efforts at acclimatisation as public enterprises, and not efforts for private gain, and acted accordingly. Hives were made upon a new construction, and a place provided, in which was kept a wetted sponge, which appears to have secured that cool and moist atmosphere necessary for bees, so that when they arrived on Thursday, per Australia, they were as lively as possible, and seemed to be in vast numbers. The two

boxes were sent through the Acclimatisation Society here, and entrusted to the care of Captain Cargill at San Francisco, who took them into his own cabin, and daily attended to the wants of his lively colonists. Fresh water was daily supplied to the sponges, and everything done that was requisite for the health and comfort of the bees. The result is an unmistakeable success, and the colonists of New Zealand are deeply indebted to Captain Cargill and Mr. Creighton for what has been accomplished. Mr. Creighton, in his letter to Mr. Cheesman, the Secretary of the Acclimatisation Society, states that Mr. Harrison is not to regard his hive as an object for private profit, but the bees are for the good of the colony, and when swarms are obtained they are to be distributed in the same way that he has been provided with them. On being consigned to the care of the Acclimatisation Society, Captain Cargill made no charge for the conveyance of the boxes, but it will be for the Society or colonists to make some acknowledgment of some New Zealand product for his care and attention to them during the voyage. On the arrival of the steamer Mr. Cheesman lost no time in having the boxes carried to the Museum, and then arranging for their future disposal. The one consigned to Mr. Farra was conveyed free by the s.s. Arawata to Lyttleton, which sailed yesterday; and the hive for Mr. Harrison was despatched per steamer to Coromandel, Mr. Harrison being apprised by telegraph of what was being forwarded. They land here at an excellent period of the year, and in a few weeks food for them will be in great plenty. It is to be hoped that they will receive judicious treatment now that they are safe here, and that soon the yellow-banded bee will be as common here as is now the common honey bee."

#### TRADE CATALOGUES RECEIVED.

- Sutton & Sons, Reading.—*List of Novelties.*  
 William Paul & Son, Waltham Cross.—*Catalogue of Vegetable, Flower, and Farm Seeds.*  
 Charles Turner, Slough.—*Catalogue of Flower and Vegetable Seeds.*  
 Webb & Sons, Wordsley, Stourbridge.—*Spring Catalogue, 1881. (Highly Illustrated).*  
 Dick Radclyffe & Co., 129, High Holborn.—*Catalogue of Vegetable and Flower Seeds.*  
 Hooper & Co., Covent Garden.—*Spring Catalogue.*  
 W. Bull, King's Road, Chelsea.—*Catalogue of Flower and Vegetable Seeds.*  
 James Yates, Stockport.—*Trade Catalogue of Vegetable and Flower Seeds.*  
 Daniels Bros., Norwich.—*Illustrated Guide for Amateur Gardeners.*  
 H. F. Sharpe, Wisbech.—*Catalogue of Vegetable Seeds.*  
 Dickson, Brown, & Tait, Manchester.—*Catalogue of Vegetable and Flower Seeds (Illustrated).*

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books (W. Brierley).**—The following works will probably suit you—Johnson's "British Ferns," published at this office, price 3s. 6d., post free 3s. 9d.; "Select Ferns and Lycopods," Mr. B. S. Williams, Upper Holloway, price 5s., post free 5s. 6d.; Lowe's "British and Exotic Ferns," price £3 15s.; and Lowe's "Our Native Ferns," price £1 8s. The two last named are published by George Bell & Sons, 4, York Street, Covent Garden.

**Dissolving Horn (J. M. Green).**—If you wish to employ the large pieces of horn for manurial purposes you cannot do better than reduce them in size by chopping or such other means as will answer the purpose better. Horn cannot be dissolved, like bones, with sulphuric acid; but if it is placed in contact with dilute caustic potash the liquid acquires a disagreeable smell, and the horn assumes the form of a jelly, and gradually dissolves.

**Making Asparagus Beds (J. M. B.).**—If you crush the old plaster and mix it with the strong soil it will render it more suitable for Asparagus. Garden refuse of all kinds, wood ashes, and leaf soil would also be valuable additions, and better than rich manure, that would make the soil too wet. Moderately light soil, containing much vegetable and gritty matter, is what Asparagus delights in, and manure is best applied to the surface of the beds.

**Galvanised and Zinc Wire (A. L. N.).**—We are obliged by your letter. The subject to which you refer has been alluded to, and, as you will see, the view you take of the question has been anticipated; but the matter, as you justly observe, is of "theoretical rather than practical interest."

**Blackening Hot-water Pipes (E. Picker).**—We mix lampblack with boiled oil to the consistence of paint, and apply it to the pipes with a brush, and it answers the purpose you name admirably, but in your case it would probably need to be applied annually. We fail to perceive the force of your remark relative to stopping the pores of the iron.

**Communications (E. C.).**—All communications that are suitable for our columns are inserted, although some weeks may occasionally elapse before their publication. It is impossible for us to acknowledge the receipt of all the letters that are sent to us, nor do we undertake to return the communications that we cannot insert. Articles and notes that convey useful information, or that are of general interest to our readers, are much valued by us, and we do not destroy any letters because they are not quite accurately written. No one knows better than ourselves that many sound practical gardeners and worthy men are not finished grammarians, but they can impart information of great value, and need not hesitate to do so, as we readily correct inaccuracies that the writers, from no fault of their own, are unable to correct. Educational facilities were not so great in England a quarter of a century ago as they are now, and it is much to the credit of many gardeners that they, through self-improvement almost solely, are able to write so well and interestingly. We do not remember having received an article from you, perhaps it did not reach us; what was the subject of it?

**Snow a Protector (B. D., York).**—It is a valuable protecting medium, as the condition of the young Wheats and Grass fields show after having been covered thickly during a term of severe weather. Your man has done quite right by "banking the snow high up round the dwarf Roses," and others will do well to follow the same practice if the frost and snow continue. The same practice may be advantageously applied to other plants and shrubs liable to injury, and also to such crops as young Cabbages, Lettuces, and Cauliflowers, autumn-sown annuals, &c. Snow may be also banked round the sides of frames, and placed on the covering on the glass of those wherein half hardy plants are being wintered. In covering young plants of any kind it must be placed on them very lightly, and in small quantities at a time, as the work if roughly done may cause injury. We have many times turned snow to valuable account in the manner indicated. It should also be placed thickly on the ground where water pipes are laid not far below the surface.

**Vines Dying (One in a Fir).**—It is so unusual for Vines to die that we should be glad to see roots of those that are yet alive, to see whether they are attacked by the phylloxera. A few fibrous roots packed in soil from the border and sent in a small box will be sufficient. The wet to which you allude would be to some extent injurious, but would not kill the Vines. Clean healthy Vines planted inside and the roots kept moist by copious waterings as needed, and mulching the narrow border with manure, would grow up the back wall, but would not bear well there after the roof becomes covered. Similar Vines ought also to grow in the outside border if the soil is of a fertile character.

**Box Edging and Snow (Puzzled).**—It will be a great mistake to incur the labour of removing the snow from the Box edgings, as if you do this and the frost continues intense much injury will almost inevitably follow. The "piles of snow," consequent on the sweeping of walks, will do no harm to the Box if it is dwarf and close, not more than 2 or 3 inches high; but if it is tall and loose it might be bent and broken with the weight, and against this contingency you might remove a portion of the snow, but not all. We once saw men employed for many days removing the snow from the Box edgings in a large kitchen garden, and all the Box so exposed was killed, and weeks of labour and much cost were involved in planting fresh Box in the spring. We have known Box edgings covered 2 or 3 feet thick with snow for many weeks, and after the thaw the Box

was as green as ever; the snow had protected it just as it protects the grass of the lawn during severe weather.

**Sulphurous Vapours (H. Godwin).**—You are quite right, these vapours are most injurious to vegetation. We know of several instances similar to the one you mention where nurserymen have suffered serious losses by the pernicious vapours from chemical works and brick-kilns. If our correspondent, Mr. Bardney, opens the ventilators of the vineries at Norris Green when the wind blows from a certain quarter where some vitriol works are established, the foliage of the Vines is destroyed in a few hours. The forest trees are also seriously injured on the side where the vapours strike them, while Conifers and evergreens are dead or dying. The shrub that appears likely to live the longest in the garden referred to is Ilex Hodginsii, and the circumstance may well be remembered by those who are planting shrubs in insalubrious localities.

**Gas Lime for Gardens (Miss A.).**—For the destruction of wireworms gas lime ought to be dug into the ground in the autumn, as sufficient to kill the grubs cannot be applied at the time of sowing or planting the crops without great risk of injuring them. A small handful, or about 2 ozs., sprinkled on each square yard of surface and well mixed with the soil to fully a foot in depth, is quite as much as is safe to apply at this season of the year; but in the autumn, as soon as the crops are cleared, nearly twice that quantity may be dug in the ground. If the lime is fresh and strong 1 oz. per square yard should not be exceeded if seeds have to be sown almost immediately afterwards; this will probably check the wireworms to some extent, but will not extirpate them.

**Aloe Unhealthy (A. A.).**—We presume the portion of leaf you have sent to us has been cut from the base of the plant, and that the leaves above are much larger and more healthy. The plant ought not to grow at this season of the year on the staircase, as growth produced in the absence of light is necessarily imperfect and unsatisfactory. The plant should be watered occasionally to keep the leaves fresh—not merely sprinkling the surface of the soil, but giving sufficient to penetrate the entire mass. Surface dribbles that so many amateurs indulge in are highly pernicious, and a fertile source of plants "damping off." The leaf you have sent is decayed at the base, which indicates that the soil at some time has been moist on the surface and dry below. The reverse of this ought to be aimed at in the wintering of plants, and especially those of a succulent nature. Remove the decayed leaves now, and apply water carefully as we have directed; in the spring turn the plant out of the pot, and if it is matted with roots apparently healthy place it in a pot a size larger, employing turfy loam and a sprinkling of broken charcoal, potting very firmly; if the roots are few and unhealthy, which we suspect is the case, cut off any decayed portions after removing most of the old soil, and place the plant in a much smaller pot, employing a free admixture of crushed charcoal with the loam. Place the plant in a greenhouse or light warm window, and keep the soil moist but not wet, and as new roots are formed healthy leaves will be produced. April will be a good time for repotting, and in July the plant may be stood in a warm position outdoors, placing its pot in one still larger to prevent the sun burning the roots.

**"Hardy Cactus" (L. R., Clapham).**—There is such a plant as you require—namely, *Opuntia Rafinesquiana*, represented in fig. 13, which, though not a member of the genus *Cactus*, is included in the same natural order, and is well adapted for outdoor culture, as it is hardy in the southern counties of England. The following particulars concerning it, by a gardener who grows it well, may interest you:—"This is one of the few Cacti which are perfectly hardy in this country, or at any rate in the south of England. It is a singular-looking and distinct plant; the branches are large and flattened, smooth, of a dark green colour, from the edges of which the numerous bright yellow flowers are produced. It will flourish in a well-drained position in the border or on the rockery where it will receive good drainage, and it will stand exposure. I have found it grow well in loam, sand, and broken bricks. It may be increased by removing the joints and placing them in pots of sand in a frame."

Fig. 13.—*Opuntia Rafinesquiana*.

**Names of Fruits (W. H. Ashwin).**—Kentish Fillbasket. (A. M.).—The Pear is Spanish Bon Chrétien, a stewing Pear. The small Russet Apple is Pit-maston Pine Apple, the large one Tower of Glamis.

**Names of Plants (F. H. H.).**—As we have many times stated, we do not undertake to name varieties of florists' flowers, still, when good examples reach us, and we can identify them, we readily publish their names. The flowers you have sent are very small and imperfect; 1 is probably *Jardin des Plantes*, and 2, *Julie Lagravère*; it is impossible for anyone to name the others. The leaf sent appears to be of *Richardia athiopica*. The *Heliotrope* is not sufficient for identification, being too small and much withered.

**Bees Buzzing in Intense Cold (Rowton).**—You inquire the reason of your bees "buzzing away as though it were a summer's night" when the thermometer stood 21° below freezing point, and ask whether something was not wrong. We reply the buzzing was the simple result of the intense cold, and if your bees were carefully protected in good hives it was in itself an evidence that all was right. Our article of last week entitled "Should Bees be Brandy-Bibbers" should be studied with this reply, in order that the whole matter may be well comprehended. When the outside temperature in the winter falls to about 40° Fahr. bees are in quiescence almost amounting to dormancy, but as the thermometer drops it becomes necessary for the insects to put forth some effort to keep their temperature sufficiently high. This they effect by agitating the abdomen, and so drawing in and driving out air with greater quickness, and increasing the oxidation (combustion) of honey or saccharine matter within them, and thus augmenting the amount of heat they are each individually capable of producing. When, however, the temperature becomes intense in its severity this expedient is not sufficient, and the wings have to be brought into play for precisely the reason that a cold-struck coachman endeavours to get warmth into his body by descending from his box and flapping his arms, by which movement he expands and contracts his chest quickly and drives along his blood, and so at length becomes warmed. The buzzing or wing-flapping raises the intake of air (oxygen) to the greatest extent, and blows, as it were, the internal fire to its greatest fervour, and so keeps out the cold. It is a

struggle for the bees, but if they be only strong and have ample supplies Jack Frost will have to do much more yet before he conquers them. The non-conductivity of hive sides is now of the very highest moment, and in relation to this matter some experiments are in hand, which have yielded curious results, which before long will be described in our columns.—F. C.

#### COVENT GARDEN MARKET.—JANUARY 19.

#### POULTRY AND PIGEON CHRONICLE.

#### AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 36.)

RELATIVE to the various machines made and supplied by Mr. Gibbs, a writer in the *Agricultural Gazette* of October 4th, 1880, observes:—"We will not stop to estimate the loss that has been sustained during the hay and corn harvests of 1878-79-80, or what the use of Gibbs' drying machines have saved the farmers, for it is now generally admitted that it has been very great, and had the use been anything like general throughout the kingdom the saving would have been enormous. Considerable improvements have lately been made in the details of construction, so that machines are now made in various ways to suit the requirements of farmers, and of different sizes. Any kind of steam engine which the farmer may possess can be used for driving the machines; they are now also made for being driven by horse and bullock gears. Water-wheels may be employed in hilly districts where water-falls are plentiful. Heated air from a coke furnace is used for drying hay, corn in the sheaf, Hops, malt, wet grain, &c., but wood or peat charcoal will answer equally well, if not better. The heated products of combustion are drawn from the coke furnace by a suction and blast fan, and driven through air-ducts into the hay in a direction the same as that in which the grass moves from the feed end to the discharge end. The temperature of the hot blast may be about 320° Fahr., and this high temperature from the way it is applied does not scorch the hay so much as a burning sun. The tedding of the hay is effected by a twofold operation thus: It is supplied at one end of the machine in forkfuls from the cart that brings it from the field. The floor has a to-and-fro motion, like the shakers of a threshing machine, which draws in the wet hay and throws it forward; but at every inch of its progress to the delivery end sets of forks on crank axles give the hay a gentle toss as it passes, shaking it up loosely to

the action of the heated air, so that wet hay from the mowing machine passes through the drier ready for the stack, cleaner and less damaged than when made by tedding machines and horse rakes in bright sunshine. The appearance of the hay in stack, the avidity with which live stock of every kind relish and thrive upon it, and the chemical analysis by Dr. Voelcker and other chemists, all prove this."

Some of the trials of Gibbs' drying machine were hardly fair for to obtain the full advantage in any wet season. The newly cut grass from the mowing machine ought to be carted directly to the drier, and stacked as fast as dried; in this way it is stated that 10 acres can be secured daily. No doubt this will to a great extent be the practice in future, and farmers who cut their grass in adverse seasons and allow it to lie about until spoiled will have only themselves to blame. It is a question of employing a sufficiency of capital only in farming to become independent of the seasons both at hay time and harvest. There are now not only the hay and loose corn-driers, but also the sheaf-drying machine. It is recorded that Mr. Ashcombe of Sewardstone cleared an acre per hour from the swathe, and dried it in fine condition at the cost of 11s. per acre, the hay realising £4 5s. per load (crop of 1879) when sent to market. It is calculated that the machine-dried hay made a profit beyond the ordinary process and cost of the rent and rates, &c., charged upon the land.

In the sheaf-drier the heated air from the coke furnace is forced into the hot-air chamber, placed immediately below the floor of the drying shed. A number of conical perforated tubes, open at the bottom, rise from the floor. The sheaves of corn are placed upon these, butt-end down, the ears being uppermost. The hot air in the chamber below is compressed upwards through the small perforations in the floor, and tubes all through the sheaf. Under these conditions it has a very drying effect, so that in the course of fifteen or twenty minutes the sheaves, however wet, are ready for stacking or threshing. The small shed exhibited by Mr. Gibbs at Manchester in 1869 only held thirty-two sheaves at a time; but sheds of any size may be made, say sufficient to hold a cartload at a time. With a shed of this size a farmer could carry, dry, and stack his Wheat, Barley, or Oats as fast as the sheaf-binder could cut and bind it, say 10 acres per day. By this plan the expense of stooking would be avoided, as also the labour of setting up stooks when blown down in stormy weather, and the loss from shaking, discolouring, and sprouting of the grain. Gibbs' drying cylinder is another machine worth attention, being adapted for drying damp grain—Hops, malt, and any kind of small seeds, often difficult to harvest in wet seasons. We commend the machines noticed to the home farmer, as they are somewhat costly, and in some instances may be out of the reach of many tenants of small farms. We have reason to believe, however, that, like most other valuable machinery, they may be let on hire in the future, as they are adapted for so many useful purposes that they would be in request at all seasons of the year.

#### WORK ON THE HOME FARM.

*Horse Labour.*—We now ask the home farmer to look forward and anticipate the work to be done in the spring as much as possible; amongst other matters, to consider and arrange what seeds of pulse or Lent corn will be required, so that the varieties may be fixed on and purchased the first favourable opportunity. A new variety of field Pea is now advertised, called Laxton's No. 1 Early Maple, said to be three weeks earlier than the old Maple, and was, it appears, raised by crossing the old Maple with the earliest white garden variety. If the seed is sown in February it is stated that the crop can be cleared off early in July, the haulm growing about 4 feet high. This variety may be worth a trial when the land is required for the growth of Turnips after the Peas are harvested. Again, we believe from our experience that on the mixed soils Barley is often sown after roots fed off when there is not the slightest probability of growing an even and plump malting sample, in consequence of the variations of soil and variations in certain parts of its condition owing to the difference in the weather during the time the sheep were feeding off the roots. In such cases we recommend sowing white Canadian Oats or black Tartarian Oats

mixed with Barley, as quantity then has the advantage. We speak from experience, for about the year 1855 we sowed half a field with white Canadian Oats and the other half with Barley, the result being that we grew eighteen sacks per acre of the white Oats and nine sacks per acre of grinding Barley. Both were sold in the same market on the same day at 28s. 6d. per quarter. This to our mind was conclusive, for we grew no more Barley afterwards upon the mixed soils after roots fed off with the land in high condition. The straw of the Oats was likewise, as regards quantity and quality for the feeding of cattle, worth as much again as the straw of the Barley; besides which the white Oats will always be earlier to harvest, and the Clover seeds take better in them than in the Barley. In all those cases where the fallow ploughing has not been completed the first opportunity must be taken to do so. Wheat-sowing may be continued upon friable loamy soils in good condition until the end of the present month, after which we prefer to put in white Canadian Oats or some other variety for which the soil and climate is known to be congenial. Besides the risk of failure of the late and spring-sown Wheat of a dry summer there is the fact, according to our own experience, that the Oats will produce as many quarters of grain as the Wheat crop will yield sacks in ordinary seasons. Whilst we are writing the weather is dry and frosty, and should this continue for a few days the home farmer will be enabled to lay out the farmyard and box dung upon the Clovers, or otherwise have it drawn to a heap in readiness to be laid out on the first favourable opportunity for the Potato or Mangold crops. When the dung is fresh and moist, in the act of making the heap by drawing the loaded carts thereon a great deal of liquid manure escapes into the soil beneath unless the precaution has been adopted of making a floor of earth upon which to build the heap. By this plan the underlying earth will be valuable, either to lay out together with the dung or otherwise to be used as a dressing for the pastures or parklands, for which it is admirably adapted.

*Hand Labour.*—The men will now be employed in the usual routine labour of the farm at this period, such as dung carting and spreading, water-furrowing, trenching in the pastures and parklands, and attending to the changing and flooding of the watercourses in the irrigated meadows, so that all parts may have an equal advantage from the deposits left by the flood water; cutting and making hedges, banking, also cutting and converting the underwood in the coppices and hedge-rows. The women should now be employed in preparing roots for the cutter and pulper, working in the fields, preparing food for the sheep. In snow or wet weather the preparation and cleaning of roots for the cattle in the boxes and feeding courts may be done. This is, in fact, women's work, for they will do as much and often more than men, they being frequently more active in such light work.

Shepherds now in different parts and districts of the kingdom will be employed in various ways in the south and south-west districts, as well as in some of the home counties where the horned Dorset and Somerset ewes are kept. These have now finished lambing, and both ewes and lambs are now being aided by generous feeding, the ewes being allowed half a pound of decorticated cotton cake each per day, with as much good hay in chaff as they can eat without waste, and cut roots either of Swedes or Mangold as much but no more than they will eat before leaving the troughs. This is the only sure method of preventing waste, and when the cake is given as meal and mixed with the cut roots it is of still more importance to avoid waste. The feeding of the lambs in advance of the ewes should be carried out in accordance with the mode of rearing the lambs, whether intended for store purposes and be sold as such at the stock fairs, or whether they are to be sold as fat lambs at the earliest period. In the former case they will do very well by receiving good sweet hay twice a day and run in advance of the ewes, eating off the greens of the Swedes or Turnips. This will do well for them up to the time of weaning, when the wether lambs will require better feeding, such as cake, &c. The ewe lambs, however, which will go with the stock ewes will require no better feeding than the rest of the flock. In the second case, when the lambs are intended for the butcher the highest and best-known system of feeding should be adopted both for ewes and lambs, for it is a fact that the higher the ewes are fed with artificial feeding stuffs the richer will be the milk available for the lambs. Again, the more liberal feeding the lambs obtain the less will be the call upon the ewes for milk, and the earlier will both ewes and lambs be fit for sale; in fact the best practice is to have the ewes and lambs both ready for sale simultaneously. In order, however, to carry out this system to the best advantage we give the ewes a full allowance of cut roots and cake with bean meal mixed with and strewn over the roots in the troughs. One pound of meal per ewe per day, composed of one-third bean meal and two-thirds cake meal, with the best Clover or Saintfoin hay *ad libitum* given as chaff, will bring out the ewes fat at the same time as the lambs are sold, or very soon afterwards.

The mode of feeding the lambs we recommend is in advance of the ewes, giving a full allowance of Carrots or Cabbage whilst young passed twice through the cutter and mixed with the best American cake meal and bean meal, or Swedish Turnips mixed and cut in the same way. At the same time they should have cracked beans and fine broken cake in covered troughs placed with back to the wind and under the hurdles. This shelter induces the young lambs to seek it, and then they find their food more readily. They should have the finest of hay given in chaff by itself twice a day, and any portion not

eaten to be removed to the ewes. To carry out this system, however, the lambs must not only be fed in advance of the ewes, but it must be in a fold cleared of the roots; for we never allow fattening lambs to run over and eat off the greens of roots, as many lambs will be injured or lost from diarrhoea by so doing. Besides this, the trough food as above stated will be found far more forcing and superior to root greens. Mangold is well adapted for ewes but not for lambs, and when the ewes are fed upon cut Mangolds mixed with meal, as before stated, it is our practice, both morning and afternoon, to feed the lambs before the ewes, so that the former may all pass through the lamb gate and be shut off whilst the ewes are being fed. Our reason for this is simply that many of the best wether lambs will often die from stoppage of urine if allowed to eat Mangold, hence the necessity of separate feeding. We give the home farmer this caution, having suffered considerable loss in our lambs before we adopted the mode of separate feeding.

#### THE MANGOLD WURTZEL FLY (ANTHOMYIA BETÆ).

THE current number of the "Entomologist" contains a carefully prepared report upon this pest from the pen of Mr. Fitch. We quote a few particulars in further elucidation of its history, supplementing what has been stated in a previous number of this Journal concerning the insect.

The observations of 1880 show that it has appeared in many places, principally in the north and the midlands. Its attacks are not confined to the Mangold Wurtzel, for the leaves of Parsley and Celery have also been mined by the maggot, and several large-leaved wild plants, such as the Burdock. Two depositions of eggs have been noticed, the first occurring in May or June, the second in July or August. These are very minute, snowy-white, and laid in batches of from four to a dozen. The full-fed larva is yellowish white, about a third of an inch in length; the head is furnished with two black hooks with which it scrapes the parenchyma of the leaf. Sometimes the larva remains in the leaf to become a pupa, but it more frequently descends to the ground. The second brood hibernates in the pupal state, the flies appearing on the wing during the spring months. Although only two broods were noticed in 1880, it is considered that under favourable circumstances there might be three or four in succession. The chief damage sustained last season was caused by larvæ that were hatched about the third week in July.

#### VARIETIES.

**RAID AGAINST WOOD PIGEONS AND ROOKS IN FIFESHIRE.**—The East of Fife Agricultural Society have commenced a raid against Wood Pigeons and rooks with the view of reducing their numbers, convinced that these birds do great harm to farm crops. Large numbers are being shot. On two days every week the slaughter goes on. Varied opinions, however, are entertained regarding the rook, which it is believed by many does much good in destroying insect pests.

— **THE BIRMINGHAM DAIRY SHOW.**—The vexed question of poultry or no poultry at the Dairy Show to be held in Bingley Hall in June next, has at length been settled in the affirmative. It was suggested some time ago that an exhibition of cross-bred poultry would form a useful adjunct to the Exhibition, and might do some good in showing the farmers what kinds were most profitable for them to keep. This idea, however, was very far from finding favour with a considerable number of the Cattle Show Council, some of whom were altogether against the exhibition of poultry at all, while others were equally convinced that a collection of what they termed "mongrels" would considerably damage the prospects of the annual Christmas Show. The real question, therefore, to be decided was, whether there should be a regular poultry show, including classes for "barn-door fowls," or whether the poultry should be dispensed with. At a recent meeting of the Cattle Show Council Mr. E. W. Badger (one of the Hon. Secretaries of the Dairy Show Committee) formally applied for permission to hold a Poultry Show in connection with the Dairy Show. A special meeting was called to consider the subject, and it was held on Thursday last, the Mayor (Alderman Chamberlain) presiding. After considerable discussion it was unanimously decided that the experiment should be tried for one year. We may add that the question has been warmly taken up by the Lord Lieutenant and Lady Leigh and other influential ladies and gentlemen, and that several prizes are already offered, for the sake of

encouraging farmers' wives and daughters to take a greater interest in the poultry yard.

— **SPRATT'S POULTRY FOOD.**—Mr. Merrick of Bristol, who is obliged to keep his fowls in close confinement, states that "by feeding them almost entirely on Spratt's patent meal they are kept in excellent health, and the food keeps in good condition for months in a closely fitting box." Another correspondent who rears several hundreds of chickens and pheasants annually, also speaks in approving terms of the value of the meal in question.

— **HOW SELLING MILK IMPOVERISHES THE SOIL.**—Where milk is sold all the mineral and nitrogenous constituents which it contains are lost to the soil. These elements have been estimated at fully two-thirds of all the cow consumes, and although this looks to be a large loss it is without doubt correct. Prof. J. F. W. Johnson says: "Every 40 gallons of milk contain 1 lb. of bone earth, besides other phosphates. Estimating a cow to yield 750 gallons of milk per year, it will require 19 lbs. of phosphate, equivalent to 30 lbs. of bone dust. If the calf is sold off, we may assume there is a loss of 20 lbs. of bone, and the waste of phosphates in the urine equals 4 lbs. And thus for every cow a dairy farm maintains, it will lose of earthy phosphates as much as is contained in 56 lbs. of bone dust." This shows what must be returned to the soil, where milk is sold, if complete impoverishment of the land would be guarded against. We are all well aware this presentation of the subject is not a new one; but we have deemed a recapitulation of these facts desirable on account of many recent statements to the effect that "the selling of milk is the most profitable branch of farming where cows are kept." It does call for a less outlay of care, work, and money without doubt, but unless purchased manures are largely made use of there will be a constant drain upon the reserved fertility of the farm. This provided for, and dairying is profitable in this order: First, butter-making; second, cheese manufacture; third, selling of milk.—(*New England Farmer.*)

— **A CURE FOR FOOT-AND-MOUTH DISEASE.**—The Duke of Brunswick has of late successfully combated the ravages of this much-dreaded enemy on his estate at Stampen, near Oels, in Prussian Silesia, by treatment with salicylic acid, the well-known antiseptic that we have previously referred to. Instead of several weeks being required to effect a cure, as with the remedies hitherto employed, truly surprising results have been brought about within a few days by this new treatment. A solution of the acid is prepared by pouring some hot water on about three tablespoonfuls of salicylic acid in an earthen vessel, and adding lukewarm water to make up a gallon. The mouth and feet of the diseased animal should be carefully washed three times a day with this liquid, and the tops of the hoofs well powdered with the dry acid after each ablution. The effect will, moreover, be greatly increased by salicylating the drinking water of the beasts by the addition of two tablespoonfuls of the acid dissolved in hot water. During the above treatment great attention must be paid to the perfect cleanliness of the stables or sheds.

— **THE BUTTER PRODUCT.**—In no single department of agriculture, says the "American Cultivator," have more experiments been made than in setting milk, resulting in great progress, not only in the extraction of butter of superior quality, but also in increased quantities. However, it is still an open question whether this notable progress in dairy husbandry is owing to superiority in the implements employed or to the superior skill of the operator. It seems to be a settled point that the butter produced at the creameries is superior in quality to the great mass of that made in private dairies, and in this case both improved implements and superior skill on the part of the operators combine to give the desired result. It needs no argument to convince intelligent persons that a dairyman in a well-appointed creamery, whose whole energies are devoted to one object, can excel in butter-making the individual who is employed in that occupation but a few hours in the week. Creameries get a product that is stamped with uniformity in quality and appearance, and that is the result of the highest skill in the art, aided by the latest improvements of scientist, inventor, and mechanic.

— **FLUKE IN CALVES.**—"A. B." writing to *Nature* says—"Can any of your readers account for the following facts?—An examination

of the liver of some six-weeks-old calves which had never touched any food but their mother's milk showed them to be infested with fully-developed fluke (*Distoma hepatica*). It is clear that the presence of these flukes does not admit of the usual explanation—viz., the ingestion with green food or water of mollusca bearing the larva in one of its earlier stages. I should be grateful if any of your readers could suggest an explanation of the mode in which the fluke entered the liver of the calf. Is it possible that the larva may have passed into the milk of the mother, and so have entered the stomach of the calf? It may interest some of your readers to know that traces of fluke were present in the livers of cattle lately killed when in high condition. The fluke had apparently been established in the liver some considerable time previous to the slaughter of the animals, and had perished on their attaining to a state of high health and vigour."

## POULTRY AND PIGEONS

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 20.)

IN the cases of poultry and Pigeons pedigree breeding is much less usual than it is with horses, cattle, and dogs. It is more difficult to identify the progeny of each pair of birds, especially with poultry, than is the case in regard to other stock referred to. No pedigree is required, and the most successful breeders are reticent in disclosing the methods adopted by them. It is thus almost impossible to adduce instances of successful in-breeding of poultry or Pigeons. At the same time it is known to many fanciers that in most classes the winning birds are the results of judicious in-breeding. We can, however, argue with certainty from the analogy of cattle. In the herd books of the owners of the very best strains of Shorthorns will be found the record of how much in-breeding has done for this breed. It is by no means unusual to find that the name of the same sire appears five or six times in the pedigree of a celebrated Shorthorn, and in some cases in-breeding has been carried even further than this. It is true that in some instances these highly bred stock become barren, but this seems to us to be merely a development of a latent tendency in this direction which existed in the family. Be this as it may, the fact remains that the most successful breeders have resorted with no sparing hand to in-breeding. We think it necessary to say this much in support of the method of breeding which we are about to recommend, because popular ideas are so very much astray on the subject.

It is perfectly common for beginners in purchasing stock to make a proviso that the birds sent shall be in no way related to each other. Authors, even, in writing about poultry, discourse upon the necessity of avoiding in-breeding, and speak of it as if it were an unmixed evil. As an example of this we would refer our readers to the paragraph on this subject in the "A. B. C. Poultry Book," and other instances might easily be cited. This general craving for fresh blood is founded partly, no doubt, upon the commonly accepted theories as to in-breeding, and partly upon the indisputable fact that in-breeding sometimes produces evil results and may be carried too far. It is also founded upon ignorance of the actual state of facts as to fancy poultry and Pigeons. These are for the most part, as at present known, the results of artificial selection, and this artificial selection has been going on in the case of many breeds or varieties for a great number of years. The show bird of to-day in most breeds is of a very different type to its ancestors of some years back. The process of artificial selection has developed certain points which are known as the chief "points" of the breed. So long as the breeding stock is composed of birds of the same family—even though they be but distantly related to each other—these artificially created points continue to show themselves, and the more in-bred the family is from birds perfect, or approaching perfection in any particular point, the more fixed does that point become in the progeny. The moment, however, that entirely fresh or foreign blood is introduced the work of years is in all probability overthrown by the natural tendency, which we have already referred to, to throw back to the original type. It may be that in consequence of one or other of the parents being very highly bred, and thus prepotent as to certain points, the progeny, or a proportion of them, will be good in these points, and that the tendency to throw back may in this way be counteracted, but it will only be counteracted as regards the first generation; and the birds thus

good in points, but what is known as loosely bred, will be worthless for the purpose of stamping their likeness upon their offspring.

We may illustrate our meaning by a reference to the Brahma fowl. The original Brahmas were of a mixed grey colour, and the Lights and Darks of the present day are said to be descended from a common ancestry. The points in each variety have been developed by artificial selection. The exquisite pencilling of the hens is a salient feature of the Dark variety, which perhaps more than any other feature has been produced by artificial selection. If the best pencilled hen that can be procured be mated with a bird of the highest quality, but perfectly unrelated to herself, it will be found that the pencilling is at once lost, and that nearly if not all the pullets are of a mixed grey colour quite wanting in pencilling. It may be that a few of them, in consequence of the prepotency of the hen, show a certain amount of pencilling, but for practical purposes the pencilling as a family characteristic is lost. We may be met in reference to this statement by instances drawn from the experience of breeders in which apparently perfectly unrelated birds have produced well-pencilled progeny. As to this, we can only say that in these instances the parent birds were probably distantly related to each other. Most strains of Brahmas through the country are more or less descended from a common stock in the first instance, and have also at one time or another been crossed one with the other. In this way it is difficult to be certain that the parent birds are unrelated in reality to each other; and successful results attained with apparently unrelated birds are probably to be accounted for by the fact that a distant connection unknown to the breeder actually existed between the birds, or it may be that the good results are to be accounted for by the prepotency of one or both parents.

In many varieties of poultry and Pigeons certain points which are deemed fancy points have been in existence and perpetuated for many years, in some cases centuries, and these points are not so liable to be lost by the introduction of fresh blood; but as a general rule fancy points, which are the result of artificial selection during a comparatively recent period, are liable to be entirely lost in the way we have indicated.

(To be continued.)

#### MATING POULTRY FOR BREEDING.

THOSE who require very early chickens have long ere this mated-up their breeding pens. The majority of poultry fanciers are content with somewhat later broods, hatched when the days are less short, and when some spring sun may be expected, and which are consequently less difficult and troublesome to rear. Many such breeders are but now making up their yards. We have had great success at the autumn shows with April-hatched birds, and with even still later chickens, and can therefore assure our readers that it is by no means too late to think about mating up desirable breeding pens; a few general rules for the guidance of novices in the pursuit may therefore not now be out of place.

It is very commonly believed that if a first-prize cock and two or three prize hens are bought at a show and put together first-rate produce must necessarily follow. We should hardly think it necessary to warn our readers against this fallacy were it not that year after year we see cases of failure and disappointment resulting from these haphazard unions. To begin with, there are some varieties the cocks and hens of which, if the somewhat arbitrary standards of perfection are at all to be attained, must be bred from entirely separate pens; about these we have frequently written, and will not now again detain our readers on the point; but apart from these breeds a certain amount of science and judgment is necessary in the mating of all poultry to ensure success, though occasionally by a lucky chance some accidental alliance may produce a cup bird. Money will not always command a well-matched pen, and often a skilful breeder will at very small cost make up a yard from which he can very confidently anticipate superior chickens, while an expenditure of £50 in an ill-assorted collection of cup birds will result in failure.

The first point to be discovered is that the males and females are of a similar if not of the same strain; first crosses of two dissimilar strains of the same breed are wont to bring out the faults of both. All races bred up to great excellence in any one point have been much interbred; the uninitiated do not know this, and are led away by fear of degeneracy to make continual "crosses" as they call them. It is the commonest thing for a beginner to think he is adopting the most approved and scientific course, and taking the royal road to poultry fame, if he discovers the two most successful exhibitors of his favourite breed and buys a cock from one and two hens from another. The result may be good, but the chances are against it being so; for probably the two great breeders each have their own favourite type for which

they have long selected their stock, and these two special beauties are both spoilt by union.

This is the first point to be considered, but then follow others. We by no means lay claim to originality when we remind our readers of a long-established conclusion among breeders of various stock—viz., that for the most part the male parent chiefly influences the external appearance of the offspring, the female its internal qualities. We have observed this constantly in our own poultry yards. From generation to generation certain beauties or peculiarities of form have been handed down through cocks, while, on the other hand, the daughters of well-known early layers have proved themselves early layers; and likewise as to the size and number of eggs laid, like has produced like. This is a point of great interest to those who aim at producing peculiarly useful as apart from peculiarly beautiful races, and one which we have before now commended to the would-be poultry farmer. To this rule as to the cock's influence on the external points of the chickens there is one partial exception—we have found the hen to have the greatest power in transmitting size to the chickens. Thus, while from small but perfect cocks we have often bred magnificent fowls, we never remember having strikingly large birds from small hens.

The age of the parent birds is not so material as their health, but as a rule the strongest and finest chickens come from hens in their second year mated with early cockerels of the previous season. In our opinion hens of twenty months old lay as well and as early in winter as pullets, and much finer eggs. Later in the season—viz., after the middle of March, pullets of a year old with strong two-year-old cocks produce large and excellent chickens; earlier than that, cocks of many breeds are not to be trusted unless the season and climate are exceptionally mild.

Another question is frequently put to us—viz., as to the respective influences of the cock and hen upon each sex of the produce. In this we have observed a difference between the case of the union of two birds of the same breed and that of the union of birds of two different breeds. In the former case as a rule each sex will in appearance generally follow the parent of its own sex. We say generally, for in some breeds there are exceptions which only great and careful observation discovers; indeed we have always considered it to be the height of poultry lore to know the particular points in the one sex which correspond with and produce particular points in the other, but, speaking generally, we believe the cockerels will follow their fathers and the pullets their mothers. For this reason we fancy that the many elaborate schemes for the breeding the sexes of certain varieties separately are as superfluous as they are troublesome, and that a little care and intelligence would produce both sexes in beauty from the same stock if only a compromise were made in one or two points difficult of attainment together. On the other hand, where crosses of two perfectly distinct breeds are tried, each sex for the most part takes after its parent of the opposite sex. We have specially been struck, too, with this fact in Pigeon-breeding, where it is common to mate two birds of different colours.

These are some general conclusions roughly drawn from our own experience; such may, perhaps, aid novices in avoiding the mistakes we have ourselves made. To recapitulate them they are briefly—

- 1, Breed from the same strain as far as possible, or at least from two strains which are known to go well together.
- 2, Look for perfection of points in the cock; for size and useful qualities in the hen.
- 3, For early chickens mate up vigorous early cockerels of last year with hens in their second year.
- 4, If cocks and hens are both of the same breed and the same strain, the colours and markings of each parent will be reproduced in the offspring of the same sex; but in crosses of absolutely different breeds the feather peculiarities of each parent will to a great extent re-appear in the chickens of the opposite sex.—C.

#### POULTRY NOTES.

THE POULTRY CLUB.—The election of officers and Committee of the Poultry Club is taking place this week. It has been delayed some days in consequence of nominations being sent in somewhat late. The members of the Committee who retire this time are the Hon. and Rev. F. G. Dutton, President; Mr. H. R. Dugmore, Treasurer; Mr. O. E. Cresswell, Hon. Sec.; Mr. R. E. Horsfall, Rev. J. D. Peake, Mr. E. Pritchard, and Rev. W. Serjeantson; all are eligible for re-election to their present or any other office on the Committee, but the Hon. Secretary begs not to be re-elected. The number of the Committee is to be increased from thirteen to twenty. The following are nominated to fill the vacant places:—For the Secretaryship, Mr. A. Comyns; and for the Committee without

special office, Rev. H. Cecil Fellowes, and Messrs. T. W. Anns, J. C. Fraser, T. P. Lyon, L. C. C. R. Norris, and Butler Smith.

**POULTRY AND THE FROST.**—The late terribly severe weather has proved most disastrous to poultry. In a famous yard of Dor-kings the combs or gills of almost every cock have been frost-bitten. The gills have generally been attacked first, and at once swell up to enormous size. We need hardly caution our readers against bringing birds in this state into a warm atmosphere or exposing them to sun. They should be put under cover—out of draughts, if possible, in the dark, and be well fed. We have found them relieved by laneing the bottom of the swollen gills, when congealed blood and matter flows out, and the inflammation seems allayed.

#### ONIONS AS FOOD FOR CHICKENS.

I FIND on reading over some American notes on Onions, that they are particularly beneficial to poultry. Fowls of all varieties are extremely fond of them, and derive great benefit from eating them. They not only serve all the purposes of food, but aid digestion and tend to ward off disease. They may be given raw or cooked. Chickens will eat not only the bulbs but the leaves when chopped up and mixed with soft food. Chickens that are allowed Onions prepared in this way rarely, if ever, have cholera, and are not likely to be infested with vermin. A very good food for laying hens during the winter months consists of cooked meat, Potatoes, and chopped Onions; the last ingredient answers the same purpose as pepper.—LA FLECHE.

#### THE BEST GRAIN FOR FOWLS.

THE question of "Which is the best grain for fowls?" is an important one for amateurs, more especially for beginners, who are always glad to know the best food to give to their fowls at different times. Grain forms a large part of fowl food at all seasons, and when good and of the proper kind nothing can be better. I prefer Wheat which weighs about 48 or 50 lbs. to the bushel. Small inferior samples are not profitable. Next to Wheat comes Barley, then Oats, and a mixture of all the three may be used with advantage. Buckwheat and Sunflower seed is not so easily obtained, but when it can be had at a reasonable price a little of both given occasionally is very acceptable. Hempseed is also a good change, but too much of it must not be given, as it is rather fattening for laying hens or stock birds. Rice may also be given at intervals; but Indian corn, which fattens them so quickly, is no favourite of mine. I have an impression if it is given in large quantities to white fowls when they are getting their new feathers, that it is the means of causing them to have a yellow hue, and if it is suddenly given in a large quantity it has a worse effect than this. The other day, happening to have no other grain, I was obliged to give fowls Indian corn the first thing in the morning, and in less than an hour we found one of the most healthy-looking pullets dead. As she was shut up in a small run with two or three others we could think of nothing that could cause her death but her sudden repletion of Indian corn. In my opinion it is highly indigestible. Ten days ago a neighbour lost a bird in the same way, and presumably from the same cause. Many Pheasants have recently died suddenly in the covers here. Some weeks ago they were supplied with no artificial food, and then Indian corn was spread about to draw them in before shooting, and I am quite of opinion that it was the Indian corn which caused their death in most instances. As a food for fowls we are thinking of giving it up altogether.—M.

#### KENDAL POULTRY SHOW.

THIS, one of the leading shows in the north of England, opened on Thursday, the 13th of January. The poultry numbered 562, the Pigeons 207. Messrs. Dixon and Charlton judged the poultry, and the last-named gentleman the Pigeons. The arrangements were upon the whole excellent, but we would suggest that another year the lower tier of pens be raised at least a foot higher; and as there is plenty of space in the passages, the fronts of these lower pens might project 6 inches further forward than the upper tier. This would do much to remedy the defective light in some of the lower pens.

**DORKINGS.**—*Coloured Cocks* (eleven) were of good average quality. First (J. White) very white on breast and tail, good profile but rather narrow, a fine red lobe, but an ugly comb. Second (B. Smith) a good bird of the Dark sort, white in lobe. Third (Carver) of medium colour, rather long in leg; v.h.c., King; h.c., Rutledge (2), King, B. Smith, Mrs. Hind. *Hens* (ten) were a very strong class. First, a well-known bird of Mr. Butler Smith's. Second (Cranston) squarely made and large, but dark in feet. Third (Smalley) too long in leg; v.h.c., (B. Smith) a grand hen, but out of sorts; h.c., Matthews. *Silver-Grey or Any Other Variety Cocks* (thirteen).—A good class, entirely made up

of Silvers. First (Cranston) good in all points and of beautiful colour. Second (Cranston) another good-coloured Silver, rather long in leg. Third (Roe) rather slight, and not so clear; v.h.c., Rutledge, Cowen; h.c., Cranston (3), Rutledge, Abbott. *Hens* (seven) were again all Silvers; a fair average class. First (Rutledge) short in leg and very silvery in plumage. Second (Cranston) of good colour, but with dark feet. Third (Cranston) a pullet sound in colour, but dark-footed again; h.c., Cranston, B. Smith.

**BRAHMAS.**—*Any Variety—Cocks* (fourteen).—Darks and Lights were shown together, which in these days is surely a mistake. First (Miss E. Cotes) a shapely Dark bird, good in foot feather, but hocked, with a little white in his tail, and a comb too high at the back. Second (Birch) the Belfast winning Light cock, now even worse in comb than before. Third (Wise) another Light, good in other points, but with a dreadful comb. Pen 86 (Brook), h.c., a very neat-headed heavily hocked Dark cockerel of good shape, though only moderate in colour; should in our view have stood second; v.h.c., Ansdell (2); h.c., J. Wood, Williams, Aspdon. *Hens* (eleven) contained some of the best hens of the season, but were not remarkable as a class. First-and-cup (Miss E. Cotes) the Palace cup Dark hen, looking grand in all other points, but too brown in ground colour. Second (Birch) a Light, good in size and shape, but with far too much of a buff shade through her plumage. Third (Aspdon) of medium size, and not very clear in marking—we preferred her neighbour v.h.c. (Percival) the Birmingham winner, and indeed should have placed this hen second; v.h.c. and h.c., Ansdell; h.c., Silvester.

**COCHINS.**—*Cinnamon or Buff.*—*Cocks* (seventeen) were a fine class, some of the commended and unnoticed birds having been leading winners elsewhere. First (Hine) a shapely very even-coloured Cinnamon of the dark-winged sort; sold at the auction for £14 10s. Second (Allen) a medium-coloured one of good size, but rather coarse in comb, and rather mealy on wings. Third (Rigg) short in leg and good in feather, but not large; v.h.c., Hind, Donkin, Brierley; h.c., Bragg (2), Brown (2), Hope, Jordan, Pickering. *Hens* (twelve) as a class were rather unsound in colour. First (Mrs. W. Steven) moderate in colour, of good size and shape, but wanting in foot feather. Second (Fleming) a Silver Lemon, good size, carrying rather too much tail. Third, Hope; h.c., C. Brown (3). We liked 128 (Clatworthy), a Cinnamon pullet, as well as anything in the class, but her tail was only half grown. *Partridge Cocks* (seventeen) were a very good class indeed. First (Sharpe) a shapely bird, rich in colour, though a little brown in fluff. Second (J. Wood) large and sound in colour, except for white in tail, but quite out of sorts. Third (R. J. Wood) good size and colour, but narrow in saddle and white tail; h.c., Southern, Wood, Mrs. F. Grant, Percival, Clatworthy, Sharpe (2), Robertson. *Hens* (eighteen) were one of the best classes we have seen this season. First (R. J. Wood) a fairly marked one of the old sort. Second (Percival) of the old sort again, but poor in marking. Third (T. Sharpe) a pullet better marked and larger than second; v.h.c., R. J. Wood, Sharpe; h.c., R. J. Wood, a beautifully marked bird; perhaps rather narrow; Sharpe (3), J. Wood, Southern (2), Mrs. F. Grant, Robertson. *Any Other Variety Cocks and Hens* had nine pens of Whites and three of Blacks; these latter, however, did not secure even a card. First (Darby) well-known winners, still wonderfully clear in colour. Second (J. Rawnsley) not quite so good in this point, although above the average. Third (Weeks) good size, but very dirty; v.h.c., Aspdon; h.c., Weeks, Mrs. W. Steven, Snell, Brierley.

**GAME.**—*Brown-breasted Reds.*—*Cocks* (seventeen) were a fairly good class. First (Braithwaite) a reachy bird, rather wanting in style. Second (Brierley) great reach again, but rather heavy in head, and not sound in tail. Third (Parker) of similar type to second, but better in tail; h.c., German, Nelson, Bothway. *Hens* (thirteen) were a moderate class. First (Martin) stylish and close in feather. Second (Braithwaite) a neat bird, in grand condition. Third (Mrs. J. Wilson) rather wanting in style; h.c., Warner, Rauthmell, Costelow, Ramson, Mrs. J. Wilson. *Black-breasted Reds.*—*Cocks* (sixteen) were again only a moderate class. First-and-cup (Brierley) a very stylish bird of good colour, but not hard enough in feather. Second (Matthews) very neat in head and long in reach, but slight and brown on thighs. Third (Brough) of good reach, but dull in colour; h.c., Fletcher, Martin, Lyon. *Hens* (thirteen) a good class. First-and-cup (Harley) a reachy bird, good in colour. Second (Brough) very smart and shapely, as also was third (Brierley); h.c., Fletcher, Matthews, Dawson, Lyon. *Any other Variety.*—*Cocks* (six) were so poor that first and second were withheld. Third (Harley) was a moderate Duckwing. *Hens* (seven) were but moderate. First (Harley) a good Duckwing. Second (Brierley) a willow-legged Pile. Third (Dickinson) a Duckwing again; h.c., Holden.

**BLACK SPANISH.**—*Cocks and Hens* (four).—First (J. Rawnsley) a good pair in all points. Second (Boulton), the cockerel rather rough in face; the pullet small, but even in lobe and broad over the eye. Third (Harrison) a fair pair.

**HAMBURGS.**—*Golden-spangled Cocks and Hens* (eight) showed a tendency to heaviness of comb. First-and-cup (Bracewell) a neat pair, good in colour but only moderate in marking and heavy in comb. Second (Bracewell) of similar type. Third (Duckworth) a moderate pair; v.h.c., Duckworth, Beldon; h.c., Rawnsley, Jackson. *Silver-spangled Cocks and Hens* (seven).—A moderate class. First (Rawnsley) a good pair in other points, but very bad in comb. Second (Beldon) much neater in head than the winners. We should have put this pen first. Third (Pickles) red lobes and heavy combs;

**h.c., Rawnsley, Patrick.** *Golden-pencilled Cocks and Hens* (nine) were a good class. First (Rawnsley) neat in head, clear in lobe, and good in colour and marking. Second (Beldon) another very good pair, pressing closely on the winners. Third (Pickles), the cock rather uneven in comb, but otherwise a fine pair; h.c., Driver, Winterburn, Duckworth, Carver. *Silver-pencilled Cocks and Hens* were five and all noticed. First (Beldon) very good in all points except that the cock had an uneven comb. Second (Pickles), the cock nicely marked, the hen failing on breast. Third (Rawnsley) a very good pair; h.c., Smith, Rawnsley. *Black Cocks and Hens* (eleven) were remarkable for their heavy combs. First (Beldon) a stylish pair in brilliant condition, but the cock's comb right over on one side. Second (Rawnsley) very good in lobe and in brilliant condition, but the cock heavy in comb. Third (Pemberton) moderate; v.h.c., Bracewell, Copeman; h.c., Rawnsley, Porter.

**LEGHORNS.**—*Cocks and Hens* (ten) contained three pens of Whites, and the rest Browns. First (Gibbs) Browns, good in shape and colour, but heavy in comb and stained in lobe. Second (Adams) Browns again, the hen a nice one, but the cock rough in comb, red in lobe, and squirrel-tailed. Third (Hurst) Browns, the cock with an enormous comb; h.c., Ardern, Bradbury.

**MALAYS.**—*Cocks* (thirteen) mustered strongly both in numbers and quality. First-and-cup (Arthur Woods) a powerful-looking dark bird of good carriage. Second (Bailey) very brilliant in condition but too soft in feather. Third (Bailey) a White, struck us as a cross-breed with a Game; v.h.c., Calvert; h.c., Yendall, Bailey, Strugnell, Lewis, Brooke. *Hens* (twelve) were not so good as a class. First (Eaves) a shapely hen of good carriage. Second (A. Wood) a smart pullet, carrying her wings too high. Third (Fisher) only moderate; h.c., Bailey, Abbott, Brooke.

**HOUDANS OR CREVES.**—*Cocks and Hens* were a very fine class, made up of ten Houdans and four Crèves. First (Mrs. Pattinson) Houdans, the hen very good in crest, muffling, size, and marking; the cock coarse in comb. Second (Jackson) a large pair of Crèves, the hen specially good in all points. Third (Mrs. P. Turner) good Houdans again; h.c., Palmer, Jackson (2, Crèves), Mrs. D. Lane, Mrs. P. Turner (2), and Mrs. Irving (all Houdans).

**ANY OTHER VARIETY.**—*Cocks and Hens* (ten).—First-and-cup (Rawnsley) a very fine pair of Golden Polands. Second (Beldon) good Silver Polands, but not equal in our view to third (Rawnsley) also Silver Polands; v.h.c., Partington (Golden Polands); h.c., Hands (Sultans), Calvert (La Flèche), Waller (Langshans).

**BANTAMS, GAME.**—*Black-breasted or other Reds.*—*Cocks* (twenty-five) were a very strong class, and all Black Reds. First-and-cup (Nelson) very neat indeed and good in colour, with hard close feathering. Second (Nelson) very smart and stylish, and in prime condition. Equal thirds (Anderton and Russell) both good birds; v.h.c., Cook, Stretch, Wardle; h.c., Fletcher, Wilson & Gowland, Roe, Buckley, Nicholson, Kennedy. *Hens* (twenty-one).—Here the Brown Reds had six representatives, the rest of the class being Black Reds. First-and-cup (Cook) a pretty little Brown Red, very sound in colour. Second (Fletcher) a stylish Brown Red, nicely laced on breast. Third (Cook) a very neat Black Red, good in colour and close in feather. Extra third, Eaton; v.h.c., Wright, Fletcher; h.c., Hore, Titterington, Nixon, Chorley. *Any other Variety.*—*Cocks* (eleven) were only a moderate class. First (J. Smith) a neat Duckwing, rather low in the carriage of his wings. Second (Davis) a Duckwing. Third (Lyon) a yellow-legged Pile, both rather large. v.h.c., Wright. h.c., J. Smith, Davis, Fletcher. *Hens* (seven).—A moderate class. First (Nelson) an evenly coloured Duckwing. Second (Eaton) another Duckwing. Third (Charnley) a willow-legged Pile. v.h.c., Cook (Duckwing), Charnley (Pile). h.c., J. Smith (Duckwing).

**BANTAMS OTHER THAN GAME.**—*Black.*—*Cocks and Hens* (eight) were all Rosecombs, and a good class. First (Harrison) neat in comb and lobe. Second (Rawnsley) good lobes, and in brilliant condition. Third (Clapham) a trifle large; v.h.c., Gunn, Anderton; h.c., J. Wood, Potter. *Any other Variety.*—*Cocks and Hens* (ten).—First-and-cup (Rawnsley) White Rosecombs, good in all points. Second (Bracewell) good Silver-laced. Third (H. B. Smith) Buff Cochins Bantams; h.c., Nixon (Silver-laced), Aspdon.

**DUCKS.**—*Rouen* (sixteen) were a wonderfully good class. First-and-cup, Messrs. Birch; second, Miss Newton; third, J. Newton; v.h.c., Rawson, Cranston (2), Bragg (2), Burn, Unsworth, Snell; h.c., Eaton, Fawcett. *Aylesbury* (five).—Not so large a class, but the winners very good in quality and size. First, J. Hodges; second, Snell; third, Mrs. Gunn; h.c., Mrs. Lane, Mrs. Turner. *Any Other Variety* (thirteen) were a good class largely made up of Pekins. First, Birch, (Pekin); second, H. B. Smith (Mandarins); third, H. B. Smith (Shell); v.h.c., Wade and Mrs. Gunn (Pekins); h.c., Earle (East Indian); Kendal, Collinson, and Snell (Pekins).

#### PIGEONS

Were in most cases good classes, and as the prizes as a rule went to well-known birds, call for no special comment.

**CARRIERS.**—*Cocks* (seven).—First, Baker, second, Stretch (Blacks). Third, R. Woods (a Dun); h.c., Yardley (Dun). *Hens* (four).—First, Baker (a Black); second, Stretch (a Dun); third, Yardley (a Black).

**POUTERS.**—*Cocks* (seven).—First (Rawnsley) a Blue Pied. Second (Baker) a Black Pied. Third (Gurthrie) a Blue Pied; h.c., Gurthrie and Woods (Blue Pies); Boulton (White). *Hens* (six).—First, Rawnsley; second, Gurthrie; and third, Baker (all Blue Pies); h.c., Boulton and Byford (Whites); Woods (Blue Pied).

**ANTWERPS.**—*Short-faced* (nine).—First, Bottomley; and second Woods (Silver Duns). Third, Hopwood (Red Chequer); h.c., Gorton and Hopwood (Silver Duns); Mays and Yardley (Red Chequers). *Any other Variety* (eight).—First and second, Rawnsley (Silver Duns). Third, Rawnsley (a Red Chequer); h.c., Mays and Preston (Silver Duns); Lister (Red Chequer). *Any Variety bred in 1880* (nine).—First, Moseley (a Silver Dun). Second, Rawnsley (a Red Chequer). Third, Bottomley (a Silver Dun); h.c., Moseley, Yardley, Rawnsley, and Bowker (Silver Duns); Rawnsley (Red Chequer).

**TUMBLERS.**—*Any colour Short-faced* (five).—First, Baker; second and third, Yardley, were all Almonds. *Long-faced* (twelve).—First, Rawnsley (a Black Agate). Second, Brunton (a Red Agate). Third, Bowler (a Black Beard); h.c., Bowler (Black Mottle); Bowler (Yellow Agate); Fowler and Woods (Red Agates); Woods (Black Bald).

**OWLS.**—*English* (nineteen).—First and second, Tresh; and third, Dale, were Blues; h.c., Lister, Woods, and Lee (Silvers); Rawnsley, Lister, and Preston (Blues). *Foreign* (five) were all White Africans. First, Woods; second, Baker; third, Leake.

**BARBS.**—*Cocks* (four).—First, Woods (a Red). Second, Baker; third, Woods; and h.c., Tresh, were all Blacks. *Hens* (four).—First, Woods (a Black). Second, Baker; and third, Woods (Reds); h.c., Tresh (Yellow).

**FANTAILS** (seven).—First and second, Loversidge (Whites). Third, Chorley (a Blue); h.c., Baker and Laidlaw (Whites).

**TURBITS** (twenty-one).—First, Woods, and second, Goldsbrough, were Blues. Third, Dale (a Red); h.c., Stretch, Brunton, Dale, and Coulthard (Blues); Baker (Red); Parkin and Holt (Yellows); Winterburn (Silver).

**JACOBINS.**—*Red or Yellow* (ten).—First, Weyman & Buchanan; and second, Holt (Reds). Third, Woods (a Yellow); h.c., Woods, Crossley, and Dale (2, Reds); Weyman & Buchanan (Yellow). *Any other Colour* (seven).—First, Weyman & Buchanan; second, Woods; and third, Dale, were all Blacks; h.c., Holt (Black); Dale (White).

**DRAGOONS.**—*Blue or Silver* (twelve).—First, Shewell (a Blue). Second, Wallace Smith (a Silver). Third, Shewell (a Blue); h.c., Guthrie and Close (Blues). *Any other Colour* (twelve).—First, Wallace Smith (a Grizzle). Second, McKenzie (a Dun). Third, Shewell (a Blue Chequer); h.c., Mays (White); McKenzie (Red); Shewell (Grizzle); Close (Blue Chequer); Byford (Dun). *Bred in 1880* (ten).—First, McKenzie; and second, Booth, were Blues. Third, McKenzie (a Dun); h.c., Wallace Smith, Grey, Pratt (Blues); Yardley (Blue Chequer).

**ANY OTHER DISTINCT VARIETY** (seventeen).—First, R. Woods (a Blondinette). Second, Joseph Wood (a Black Trumpeter). Third, Baker (a Fairy Spot); h.c., Gatty (Red Magpie); Gatty (Frillback); Yardley (Owl); Mays (Nun); Yardley (Blondinette); Dale (Nun).

#### OUR LETTER BOX.

**Incubators (Dalla).**—Most of the incubators now in the market have given more or less satisfactory results. We refer you to our columns of last week for accounts of successful hatching. It must be borne in mind that in this matter success depends quite as much upon the operator as upon the machine used. There is no great amount of intelligence required, but a close observance of the directions given as to management is indispensable. The artificial rearing of the chicks is practically rather more difficult than the hatching, as just at first the little ones require much judicious attention; many are killed by over-kindness, many by neglect. We intend shortly to commence a series of articles upon this subject, which we hope will be of use to our readers.

#### REMARKS.

9th.—Fine, with bright sunshine in morning; cloudy afternoon; moonlight evening.  
10th.—Cold and dull, little sunshine in forenoon.  
11th.—Fair, calm, and overcast; slight snow in evening.  
12th.—Snow in early morning, covering the ground about 1½ inch in depth; very cold but fine day with bright sunshine; moonlight night.  
13th.—Sharp frost; overcast morning; bright sunshine at 2 P.M.; fine afternoon; starlight evening.  
14th.—Fine, calm, bright, and very cold.  
15th.—Rather misty, and excessively cold; slight sunshine in forenoon; overcast in evening.

A very cold week, with intense frost towards the end.—G. J. SYMONS.

### THE FUTURE OF GARDENING.

**I**T is now many years since I occupied your pages with any of my remarks on horticulture, although the old love of holding communication with your readers has often been strong upon me.

My time, as many of your readers well know, has been so fully occupied during the past ten years, that it has left very few opportunities of indulging in what long ago was a constant source of pleasurable and recreative enjoyment to me. Although I have not been able to write in your pages for some years, I have derived a large amount of information from many of your correspondents who have so ably conveyed, through the medium of the *Journal of Horticulture*, their thoughts and practical experiences on the various topics connected with floriculture and horticulture generally.

I have always read with much interest the new year's addresses so ably written by your respected correspondent "WILTSHIRE RECTOR." The excellent article from his pen which appeared on the 6th inst. has naturally aroused my dormant scribbling propensities. The spirit of "WILTSHIRE RECTOR'S" theme is so much in unison with my own thoughts, and so congenial to my feelings, that I am impelled to fully indorse all he has said in respect to the future of gardening.

Like your correspondent, I am fully convinced there is a great and noble future in store for horticulture, and the greater the amount of energy thrown into it by horticulturists of the present day so much the greater will be the benefits conferred on this and future generations.

I hope and believe I shall live to see the day when a flower show will be held in every village in the United Kingdom; and "WILTSHIRE RECTOR" will pardon me for saying that I believe this would do as much good as all the sermons he could preach, even were he more eloquent in the preaching of the Gospel than he is in discoursing horticultural matters. We want to educate the taste of the people, and by that means reach their better nature, which would speedily become amenable to the influences which surround them. A well-cultivated cottage garden is a pleasant sight, and a sure sign that its inmates are happy and contented. The child born in many such an humble English cottage has become in after years a benefactor, not only to the generation in which he lived, but revered for ages after.

If the many acres of waste land we see in various parts of the country outside the cottage gardens could be added to these gardens, a vast amount of benefit would be conferred

on many thousands of honest cottage tenants; they would thus be enabled to cultivate large quantities of fruits and vegetables, which could be sent to the nearest markets and be the means of placing within their reach an additional means of happiness and contentment.

"WILTSHIRE RECTOR" has very ably dealt with the farmer's altered position. He is quite right in saying that other means should be tried when it is found that the old style of farming no longer pays, and when by reason of our uncertain climate the old stereotyped crops grown from generation to generation can no longer be depended on as a source of income. This being so, other things should be tried. I quite agree with "WILTSHIRE RECTOR" in thinking that fruit trees should be planted in considerable quantities in our fields, and also that vegetable culture should be more generally introduced by the agriculturists of England. There is, and ever will be, a widespread demand for all kinds of fruit and vegetable produce, and the facilities now offered by our railway system for conveying the products to the various centres where they are most in request lends additional security for the cultivation of fruits and vegetables.

Reverting again to the future of gardening, I think many will give me credit for the part I have taken in trying to help the advancement of an art which is part and parcel of my nature. My writings, I think, will also show that I have devoted a considerable amount of care and time to its advancement, and that I have tried to do so at no trifling cost; and I solemnly affirm that in the change recently made in the style of my undertaking I have been actuated solely by the wish to benefit my fellow men, and not in any way to injure others. The impression indissolubly impressed upon my mind is, that anyone who can benefit horticulture by increasing its sphere of influence and prosperity must be the means of increasing the trade and considerably enhancing the pecuniary position of those who are engaged in it.

The world is wide, and in this little England of ours there is plenty of room for many lovers of horticulture to succeed in making a name, and in advancing that highly humanising art, which will, I hope, clear away the cloud of prejudice, and cause the future workers in the wide field of horticulture to grasp the right hand of fellowship tightly, and to banish from their thoughts every invidious feeling.—JOHN WILLS.

### THE VEGETABLE SUPPLY.

IN reply to your correspondent, "W. P. B." (page 44) who impugnes the correctness of my article entitled "The Future of Gardening," not "Future Gardening," as he writes, I will first say that I never had London in my thoughts while writing, or referred to London in any way, as my critic will see if he reads it correctly, as I know well that London has an over-supply in many articles of diet; thus I have often watched the catching of fish close to a house I stayed in, which I could not buy, all being bought up for the London market. Further, if "W. P. B." takes pains to read my article correctly he will see I referred chiefly to poor tradesmen's families; for as yet the very poor—the labouring class in towns—are so ignorant of cooking that they cannot cook a tasty dish. My hope lies in the class above them. I aver that the supply of vegetables in country towns, or in towns in the provinces, some very large, is not adequate to their population, but I believe that a due

supply would cause and create a demand; also that the poor who go from villages straight to towns would gladly buy vegetables, from long use of them from their gardens in the country. London is an exception, and wholly out of court on the subject, so far as the lowest class is concerned. In another generation when board schools have done their work it may be different.

Progress is slow, improvement slower, so long as we have a thriftless ignorant residuum, usually too idle to attempt to cook food well. Vegetables will not be bought by this residuum; but there are classes above this, which even "W. P. B." allows, do buy such viands, and I aver that these in most towns have not a sufficient supply. The shops are few and poor. (Oh! contrast their fewness with the many public-houses!) Then, again, it is not by shops only, but by carts and barrows calling regularly in the smaller streets at fixed and suitable hours, that a demand will be created and supplied. Look at the faces of the poor, and especially of their children; do not these crave, aye, plead mutely by their pallor and pinched look, for a more wholesome diet? Surely they do, but it is gradually that we can reach and do such good: now a few just above them, then a few of them, and then more. A hundred years ago, and even less, there were no baths in even upper-class houses except foot baths, now every educated Englishman takes his tub of a morning. Improvement, I have said, is slow; as someone wittily wrote, "It is the largest room in the world," but still it does go on and will. Health and comfort, physical power and mental energy, and even morality, depend a great deal upon good nutritious diet, a diet in which vegetables ought to have a larger proportion.—WILTSHIRE RECTOR.

I HAVE long been an admirer of "WILTSHIRE RECTOR," as he generally contrives to make his communications both readable and instructive. I read and re-read his "seventeenth annual address" (page 1) with the intention sooner or later of making an amendment to that part of the address relating more particularly to the vegetable supply of the future. I have the less hesitation in doing this, since I am of opinion if gardeners can make any admissible suggestions to benefit the farmers they should do so, simply because the prosperity of the country is at stake, and no class more than gardeners more keenly feel the effects of short rents. The latter motive may appear selfish, which word must not by any means be applied to the "WILTSHIRE RECTOR'S" remarks on the vegetable supply, unsound as they appear to me to be.

The unfortunately too true facts briefly adduced by "W. P. B." (page 44) no doubt surprised many readers, and I trust our reverend friend will submit those notes to the perusal of Sir Gabriel Goldney, as there is not the slightest doubt that many well-meaning M.P.'s and others are offering advice upon a subject they know but little of. Market gardening at one time was most profitable; now, in the vicinity of London at all events, it is generally understood to be "all a lottery," with more blanks than prizes. There are too many engaged in it, and the foreign competitors with their superior advantages have finished the work. Nor does it appear that the consumers are much benefited by the over-abundance of garden produce.

The culture of vegetables to be profitable is very different and much more expensive than the ordinary farm crops, and many farmers who have turned their attention to them have regretted having done so. They commenced under the impression that they had found a "new and probably prosperous path," concentrated much of their capital (probably already too little for the extent of their farms) on a few fields, the remainder of the land being only half cultivated, and as a matter of course yielded poor crops. The success attending the vegetable culture may have equalled their expectations, and still more vegetables are then grown another year. Then comes a bad season; "no returns" from the salesmen, and our friend with all his eggs in one basket may be missing at the next rent audit.

Sir G. Goldney's friend doubtless will double his acreage of Onions this season, and others hearing of his success will imitate him. The original two acres probably about met the local demand, and every additional acre grown will most certainly injuriously affect the sale. The cost per acre (£20) is fairly computed. What if this expensively grown crop decay in clamps by hundreds of bushels? There is no certainty of a good sale for Onions, or more would be grown. If there is a demand for them in the provinces they would certainly be sent from the metropolis. The Pea trade only really pays when large quantities are bought up in London for the manufacturing districts. The same with Runner Beans, as there are by far too many grown to meet the metropolitan demand. To grow, pick, and send these by rail or otherwise at the rate of 6d. per bushel is simply ruinous, yet there were times last season when less had to be taken, and tons were never sold.

The extraordinary high prices realised last winter for greens of the commonest description has been the cause of greatly increased quantities of Savoys, Purple Sprouting Broccoli, and Brussels Sprouts being grown, with the result already given by "W. P. B." Sprouts, unless of the very best description, picked on January 14th (a bitter cold foggy day) the next day only fetched 6d. per bushel, and many were unsold. All the senders evidently anticipated a short supply, and pressed the poor women to pick them. I know of no colder work, but market growers, as times are, cannot afford to be sentimental; all the gin given by way of furthering the work was a dead loss, and much more besides on the date mentioned.

One of the favourite crops with farmers are Potatoes, and of these again there appear to be too many this season. They cost much to grow them well, and £4 10s. per ton is not generally a very profitable price for the best samples. Some of the salesmen have great quantities accumulated in their warehouses, as a difficulty is experienced in getting rid of inferior samples.

It may be urged that I take a pessimist's view of the case, and that the trade generally may yet regain its old elasticity. I trust it will, but it will not result from an addition of growers—quite the reverse. An improvement may eventually be effected in the tastes of the poorer classes, but the revolution promises to be ruinously slow. Let farmers be content with smaller farms and till these more, as their forefathers did. Cattle, pigs, and poultry are conspicuous by their absence on many farms, and even in this purely agricultural district milk and butter are bought with difficulty. Market vegetable farms to be profitable should in extent be in accordance to the capital and ability of the holder; they should be near to large towns to admit of the cartage in of the produce and the loading out with cheaply bought manure, which must be freely used. To sum up, instead of a large farm concentrate capital and faculties upon a few acres, cropping these heavily, and thereby save a considerable sum otherwise to be paid in the shape of rent, tithes, and taxes.—W. IGGULDEN, Orsett, Essex.

#### NOTEWORTHY PLANTS.

AMONG the numerous readers of this Journal there are many who possess or have charge of large collections of plants, and who are not merely interested in the preservation of those they already have, but wish to add to their numbers such novelties as are most deserving of cultivation, to obtain some of the old neglected favourites which are now rarely seen, or to gain particulars concerning the relative merits of the best and most distinct decorative plants. To afford a little assistance to such plant-lovers, and as I am favoured with opportunities of seeing a very large number of plants (including the latest introductions) under a great variety of conditions, I will occasionally give a few descriptive notes upon the most remarkable that come under my observation.

**SPATHIPHYLLUM PATINI.**—A beautiful Aroid of comparatively recent introduction, but which deserves to be widely known, as in some respects it is unsurpassed in its family. An admirable coloured figure of it was published a short time since in "L'Illustration Horticole," which represents a specimen in M. Linden's collection, and very fairly indicates the general character of the plant. It is of elegant habit, moderately dwarf, with stalked narrow lance-shaped deep green leaves, and scapes about twice the height of the leaves, bearing a cylindrical green spadix about 2 inches long, and a pure white tapering spathe of similar length, and an inch in width at the base. A specimen of moderate size may have from four to nine scapes, and as the spathes remain in good condition for a long period the plant is of no mean decorative value for the stove. It is found in some English collections under the name of Anthurium candidum, and was described in the "Gardener's Year Book" for 1875 as A. Patini, but it has been now definitely referred to the genus Spathiphyllum. It is a native of New Granada, and was sent to Europe by M. Patin about the year 1874.

**PRIMULA SINENSIS DELICATA.**—One of Mr. H. Cannell's varieties of the Chinese Primrose, for which a first-class certificate was awarded at the last meeting of the Royal Horticultural Society. It is of good habit, with the long elegantly-cut leaves which characterise the "Fern-leaved" forms. The flowers are 1½ inch in diameter, neatly fringed, of a soft pink hue, and with a yellow eye, and are borne in compact trusses well above the foliage. The tint of the flowers is very distinct and pleasing, the term "delicata" being an appropriate designation.

**CARNATION ANDALUSIA.**—Another of the plants recently certificated at Kensington, which deserves a few additional remarks. It was exhibited by Mr. Hill, gardener at Tving Park, Herts, who informs me that his employer, Sir N. De Rothschild, obtained it last year from a friend in Barcelona, where it is frequently seen in

the flower markets. Although the flowers are almost devoid of fragrance, their clear pale yellow colour, fulness of form, and prettily-fringed petals are decidedly attractive, especially as the free-flowering habit renders the plant of considerable decorative value, and from this quality being well marked the certificate was awarded it as a "decorative variety."

**CYPRIPEDIUM PURPURATUM.**—This species has no pretensions to be considered a novelty, but it is not very frequently seen, though several of the metropolitan nurserymen include it in their collections, and it is now flowering. A few particulars concerning it may not be devoid of interest. It was figured in the "Botanical Register" in 1837, where it is stated that Mr. Knight of the King's Road, Chelsea, introduced it a year or two previously from the Malay Archipelago, though the drawing was prepared from a plant in Messrs. Loddiges' collection. It is of neat habit, the leaves pretty, bright green, with spots of a darker shade. The reddish scapes are 6 to 8 inches high, each bearing a flower about 3 inches in diameter from tip to tip of the petals; the latter are half an inch in diameter, margined with hairs of a purple tint, green at the base, with dark spots; the upper sepal is of medium size, white streaked with purple; the lip is rather small, and similar in colour to the petals. Though not one of the most handsome of the genus it is neat and worth growing.

**CYDONIA (PYRUS) JAPONICA ALBA.**—It is not so generally known as might be expected that this plant is admirably adapted for forcing, though some gardeners value it very highly for that purpose. I recently saw plants of the variety at Messrs. Cutbush and Son's Nursery, Highgate, where they are grown in pots and placed in an ordinary forcing house a few weeks before they are required in bloom. The flowers are now expanding freely, large, of good form, and pure white; the streaks of pink which are seen in the flowers of plants grown out of doors are absent, though the exterior of the unexpanded buds have a tinge of colour. For yielding a supply of flowers at the present season when the demand is so great the plant is of considerable utility, and it only requires similar treatment to that afforded the majority of such when forced—namely, a soil of rich turfy loam and occasional supplies of liquid manure.

**RUBUS AUSTRALIS.**—An elegant New Zealand plant rarely seen in cultivation except in botanic gardens and a few large collections. It is usually regarded more as a curiosity than as a decorative plant; but small specimens in pots are very graceful when well grown, and are decidedly attractive in a greenhouse or conservatory. Some examples in Mr. Cutbush's nursery show its character admirably, and attract much attention from visitors. The peculiarity of the species consists in the long slender dark green stems and leafstalks and the trifoliate leaves, which are reduced to three linear midribs terminating in a small oval leafy expansion. The stems and petioles are thickly studded with small white spines, which contrast strangely with the prevailing dark green tint of the plant. It has been grown out of doors in various positions, but it is not quite hardy, at least in the north of Britain, as the late Mr. William Gorrie recorded in his pamphlet that both the species and the variety *cissoides* were killed in the winter of 1879 at Raitt Lodge, Edinburgh.

**ANSELLIA AFRICANA.**—One of the most distinct and attractive of winter-flowering Orchids, and which during the last few weeks has been in fine condition in several metropolitan gardens and nurseries and at Kew, where it is remarkably well grown. It produces a large branching panicle commonly bearing from two to three dozen flowers, but occasionally a considerably greater number, which are about 1½ inch in diameter; the petals and sepals being obtusely elliptical in form, of a pale yellowish green ground colour, thickly marked with large roundish or bar-like blotches of purplish maroon or chocolate. The greater portion of the lip is pale yellow, and the general appearance of the flower most striking and handsome when viewed in front, but they are so twisted or widely spreading on the panicle that comparatively few are seen at one time, a circumstance which slightly detracts from its beauty. It succeeds in the East Indian house in pots, and when flowering a cooler position may be assigned to it where the blooms will last for many weeks. It is a native of the island Fernando Po in the Gulf of Guinea; and one or two varieties are known, that named *gigantea* being the best. A faithful figure of the species appeared in the "Botanical Magazine" in 1857, about thirteen years after its introduction.—L. CASTLE.

**GISHURSTINE.**—Since you published your good opinion of Gishurstine (page 8) I have received other very good reports. These, with those of the leading gardening papers, will shortly be extensively circulated in the gardening world; but before the power of Gishurstine to keep boots dry can be made generally known the impending thaw may come, and an excellent opportunity for testing a waterproofing material thus be lost. I therefore beg the favour of your publishing the accompanying report just received.

The authority of the writer is so great and the opinion so decided that it ought to ensure Gishurstine being fairly tried. I may add, that though Gishurstine was originally devised for thick country boots it is now used also on ordinary walking boots over upper leathers and soles, and even on ladies' and children's boots, as it takes a good polish with blacking. It can be had from any nurseryman or seedsman.

Report from Mr. A. F. Barron, Royal Horticultural Society, Chiswick Garden, W., 22nd January, 1880.—"I write to thank you for bringing the Gishurstine under my notice. I have tried it myself, and my foremen in the garden have tried it, and found it excellent—far superior to anything we have ever used."—T. I. O. G. C.

## VEGETABLES TRIED AT THE EXPERIMENTAL GARDEN AT GIRTFORD.

(Continued from page 42.)

**Onions.**—Of the spring-sown the earliest to bulb and to come quickly off the land was the Cracker, an American sort from Mr. Jas. J. H. Gregory of Marblehead, U.S. It was a flat bulb with sulphur-coloured stem, but does not keep well. The best of all the keeping varieties appears to be New Zittau Round Yellow, a large handsome somewhat globose variety of the White Spanish type, the skin being of a rather redder tint; it will prove a solid and good weighing market Onion. Of autumn-sown sorts Trebons was the largest and best ripening, better in both the past seasons than Giant Rocca. The earliest was Early White Italian Marzajole.

**Peas.**—Upwards of one hundred established varieties were again tested, and of many of them numerous comparative sowings were made. The Earliest of All, a round blue variety, proved true to its name, the pods being fit to gather three days in advance of the best type of Harbinger and a week before Ring-leader; the height is 2 feet 6 inches, and in most other respects the Earliest of All was much of the character of Ring-leader. Of all the dwarf varieties Minimum, a very compact-growing early white wrinkled variety, is the dwarfiest, as it will bear favourable comparison with "Nain très hâtif à Chassis" of the French, which is a very dwarf selection of Tom Thumb. Minimum is also extremely productive, and this combined with its dwarf habit and excellent flavour render it also well adapted for forcing. Messrs. Bliss's American Wonder, which has been tried two seasons, is an excellent dwarf variety, having a good deal of the character of Little Gem as originally sent out by Mr. Turner. In early market varieties Messrs. J. Carter & Co.'s selection from William I. proved one of the best, the pods being of a deep green colour and coming very true in character, showing the careful attention this firm give to such matters. Amongst main crop 3 feet Peas John Bull, a very large-podded blue wrinkled variety, was very conspicuous in many comparative sowings, being unapproached in size and beauty of pod, fertility, luxuriance, and regularity of growth by any other Pea of its class. In tall varieties Telephone, which appears to be a well-filled blue-wrinkled Superlative, is the finest and best, and if I desired to grow only one tall Pea it would be Telephone.

**Potatoes.**—The best of all the American, if not the best of all recent introductions, is in my opinion Beauty of Hebron. It is one of the earliest of the transatlantic sorts, preceding Early Rose and producing very large and handsome tubers of superior quality, the skin of a paler tint than "the Rose." It has a moderate top only, and if it were not for the slight tint of skin it would command a high price in the market. It was grown at the Garden on a considerable scale under parallel circumstances with Myatt's Prolific; and although the market price of Beauty of Hebron was considerably less than Myatt's, the former, from its wonderful productiveness, proved the most remunerative. Scotch Champion was unsurpassed both in quality and quantity of produce as a round late variety, and was but slightly diseased. Magnum Bonum proved very productive, but in quality it is not equal to Champion, and, as previously alluded to, it showed disease materially. It is nevertheless a valuable acquisition.

**Rhubarb.**—Through the kindness of Mr. Veitch I was enabled to try many of the early varieties of Rhubarb, and of these Johnstone's St. Martin's was earliest and best in quality, although it has the disadvantage of not being so good colour as some of the succeeding sorts. Crosses of these, however, raised in the Garden inherit the good qualities of St. Martin's combined with a better colour.

**Squashes and Marrows.**—The best Squash was a green-skinned American variety received from the United States, the flesh, however, being deep yellow, and even in the young state firm and rich in flavour, and much superior to the yellow varieties. The

flavour of all the Squashes is quite distinct from and richer than most of the Vegetable Marrow type. Of the latter class Early Cocoa-nut is a handsome oval variety of medium size and good quality, producing a great quantity of marketable fruit.

*Tomatoes*.—Of these the earliest and best for open-air planting was Messrs. Vilmorin's Pomme rouge améliorée. Tried against Conqueror, Paragon, and other early sorts it is unsurpassed, as it is not only quite as early but of large size and handsome shape, and of a deep waxy scarlet colour; flesh firm, and quality very good. In ordinary or cool seasons I think this will be the best market variety for open-air growth.

*Turnip*.—The only Turnip grown at the Girtford Garden during the past season and worth eating was a round flat yellow Russian variety named Petrowskische, nearly all the white varieties being stringy and unsatisfactory in 1880.—T. LAXTON, *Bedford*.

#### IMANTOPHYLLUM MINIATUM.

THIS superb-flowering Amaryllidaceous plant was introduced from Natal by Messrs. Backhouse, in whose nurseries it first bloomed in 1852 or 1853. It is nearly allied to the Clivias. It is an evergreen, having green lance-shaped leaves. The flower stem rises a foot high, surmounted by an umbel of flowers varying in numbers to fifteen or more, according to the age and vigour of the plants. The blossoms when fully expanded are about 4 inches across, the flowers being red or salmon in colour, and yellow at the base of the petals. The flowers are produced successively from the same head, and form a fine head for some time. The plant flowers at various times, continuing to make fresh growth in an intermediate temperature, but seldom flowering more than once a year in a greenhouse.

I have now several in flower in a temperature of 55° to 65°, in which it generally commences blooming about the new year, and continues to throw up flower stems from the stools or several divisions of the plants over many weeks, and the plants being of considerable size from retaining the offsets when potting they have a fine effect. Grown singly in 6 or 7-inch pots they are useful for decoration. Potting is best done in spring after flowering, removing the old effete soil, draining efficiently, employing a compost of turfy loam. Supply water freely when growing, affording weak liquid manure occasionally, and never allow the soil to become quite dry. A light airy position is essential.—G. ABBEY.

#### THE SEED ORDER.

IN continuing my remarks on this subject from page 23, as some correspondents have asked for quantities I will name the quantities actually ordered of Peas and some of the more important vegetables, although I hardly think they will be of much service to other people. The establishment I have to supply is one of the largest, and I aim to have Peas from the end of May to the beginning of November. It is better to have too many at one time or at all times than to have a breakdown in the supply, and if varieties of the best quality only are grown there is little trouble in having the produce consumed. Of William I. Pea 4 quarts are needed, and these will be sown in two batches. Of Essex Rival 8 quarts, to be sown in three or four batches; the first sowing to take place simultaneously with the second sowing of William I., and the last sowing ten days or a fortnight after the first sowing of G. F. Wilson and Veitch's Perfection. Of G. F. Wilson and Veitch's Perfection 6 quarts of each are required when no other main crop Pea is used, and for the latest supply 4 quarts of Omega, or, if that cannot be obtained, then say 3 quarts of Ne Plus Ultra.

Beans come next in the catalogue I have before me, and of these I order 4 quarts of Seville Longpod and 8 quarts of Broad Windsor.

Of French or Dwarf Kidney Beans, as the main object is to have them for forcing, and to save some new seed for that purpose earlier than I could buy it, I order 6 quarts of Osborn's Forcing, which is an excellent Bean for all purposes. Where French Beans are only required for outdoor work the old Negro Longpod is not easily surpassed.

Of climbing varieties I am not yet tired of the flavour and peculiar roughness of the old Scarlet Runner; indeed I prefer it to any other Bean either dwarf or tall, but it does not look quite so well when cooked as the best of the dwarf varieties do. It is, however, a most productive vegetable, and one sowing keeps up a continuous supply for servants and those who prefer it all through the autumn from the beginning of July. When I do not save seed of Scarlet Runners, which is the safest plan now there are so many reputed improvements, I order 4 quarts.

Of Asparagus there is little choice but in names; anybody's

selection will do if it has been saved from healthy plants, and half a pound is sufficient.

The selection of Beet is much more difficult, for somehow a notion has become very popular that the darker-leaved varieties are the best to grow. This may be the case when they are grown for ornament, but we want flavour here as well as appearance, and my experience says there are none better than Pine Apple Short-top and Nutting's Selected for eating; of each of these I have 6 or 8 ozs. in a doubtful season. Dell's Crimson is grown largely for decorative purposes, but is made no future use of.

Borecole is a very important vegetable, of which I grow Dwarf Green Curled in large quantities. The tops of these succeed the Savoys for common use, and the side shoots keep up a good supply in early spring. I order 2 ozs. of this, 1 oz. of Cottager's Kale, and 1 oz. of Asparagus Kale. The last-named supplies greens of excellent quality long after spring Cabbages come in, and for my own taste I prefer them to Cabbages.

Of Broccoli the most important variety is Snow's Winter White, the hardiest of all Broccoli, and one which affords the longest supply—viz., from November to February. But you must have it true, as there are many spurious varieties sold for it. I have three packets of this, or half an ounce if I can get it by weight, and no other autumn or midwinter Broccoli is necessary. Veitch's Spring White makes a good succession to Snow's, coming in during February in a favourable season, while Model and Lauders' Goshen are splendid late varieties of hardy constitution and dwarf habit, one succeeding the other by about a week. A packet of each of these is sufficient for my purpose.

Of Brussels Sprouts I prefer a selection of the variety with incurved leaves, such as what is called the imported seed generally produces; but of course I know that any good selection made in this country is equally to be depended on, only unfortunately there are many bad stocks about. This is probably the most important of all green vegetables, and brings the greatest amount of produce, as we gather continually from August to February off the same sowing.

Of Cabbages I grow only our local variety known as Wheeler's Imperial, which has been in existence here over thirty years. It is a very different vegetable from that sold by the London seed firms under the same name, and is probably identical with what is now called Heartwell Early Marrow. Half a pound of this is sown about St. Swithin's day, and a pinch of it a fortnight earlier.

Cardoons are a very important crop where there is a French cook. Sometimes I succeed admirably, but this year all but half a dozen roots ran to seed, for which I blame the stock, as the cultivation was most carefully attended to.

Of Carrots, the French Forcing is used for a frame, and for one small sowing on a south border 4 ozs. suffices for this. Afterwards Early Nantes or a good selection of Early Short Horn only is used, and is sown in succession till the middle of July; this takes 2 lbs. of seed. The crop sown last July is still in the ground unprotected except by its own foliage, and is in beautiful condition.—WM. TAYLOR.

MR. WM. TAYLOR admits this annual duty is a difficult one. It is difficult for the practised gardener, as every such gardener knows and proves as he year by year wades through the almost interminable pages of present day seedsmen's catalogues to find out those seeds he always relies upon, and those which he made notes of through the past summer to try in the coming one. To find these is difficult enough, and then to select the novelties he intends to experiment upon more difficult still. Speaking of novelties, I may say that every good gardener grows a few novelties yearly—always a few, but only a few, and in addition to and supplementary of his usual crop. He never allows them to stand in the place of a crop, for he knows if he does he may have a bitter lesson taught him, as they may fail him utterly, and that in an important particular and at a most special time. So let me advise young gardeners to have a novelty or two by all means; so only will you keep yourself abreast of the times. But only have a few, and let them be exclusive of the demands of the house; then, if they succeed, you can always manage with an excess of production.

But seeing the generally admitted difficulty of making a good, useful, and economical selection of seeds, even by the professional gardener, why not do publicly as I often do privately? Advise small gardeners—gardeners who have more devotion to their garden even than many professional gardeners, but without much practical knowledge of seeds—to purchase one of the collections of seeds which most large seed establishments advertise to suit the wants of all sections of gardeners. These I can testify are all really useful, and generally adapted for the wants of any garden. We know that amongst gardeners there are many extraordinary

men, and these will want extraordinary seeds. I should never dream of advising these to buy a collection, but the average of gardeners would find the collections very accommodating. They save much time in selecting. They introduce to notice many varieties of which we were ignorant, varieties which on our soil and with our climate do better than some which we have chosen in years gone by. They also bring us a larger amount of seed for our money than we should have if we had chosen all the extraordinary seeds which we fancied, or which we had recommended to us.

One thing I may say therefore to those who decide to order a collection this year. Sum-up what it has cost you for seeds the last two or three years, then strike the mean, and in ordering a collection you may choose one somewhat cheaper, and then you will have more than you expected. It is quite true that these seed-growers do grow large stocks of the very best things which are profitable, and these are they which they make up into collections, so that the charge which people sometimes make against these seedsmen—that in collections they work off all their accumulated old stocks, whether good or not—is not true; and when we think of it, it would be strange if it were true, because to do so would be about the worst thing that they could do. I have never found it so, and I have had collections for many years for various sized gardens too, and I have always found them good, and many times excellent in the varieties sent, and much better than if I had gone to the trouble of selecting my own. Let me advise all those who do not like to trust to their own judgment, or who have not time to spare to hunt up special varieties, and who wish to be economical, to order a collection according to the size of their garden, and I venture to say that once having adopted that plan they will not return to the old way of making a selection of their own.—EXCELSIOR.

#### THE METEOROLOGICAL SOCIETY.

THE Annual General Meeting of this Society was held on the 19th inst. at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. The report of the Council for the year 1880, which was read by the Secretary, refers to subjects of considerable importance, and affords substantial evidence of the interest taken in meteorology by the scientific and general public. Amongst these may be mentioned the great success of the new climatological stations, as shown by their increased number, and by the regularity and care with which the observations have been made and recorded, and the returns forwarded to the Society. The Council also advert to the number of new and improved instruments exhibited at the meeting held in March last, to the increase in the number of Fellows, fifty-two having been elected during the year, and finally the numerous papers which have been sent to the Society from various parts of the world, embracing records of the climate of several important localities, respecting which but little has hitherto been known in this country.

After a vote of thanks had been passed to the Council for their services during the year and to the Institution of Civil Engineers for allowing free use of their rooms, the President delivered his address, in which he traced the history of English meteorological societies from 1823 to 1880. The earliest English effort at forming an English meteorological society, or at any rate at securing observations made with comparable instruments recorded upon a uniform system, was made in 1723 by Dr. James Juring, who was then Secretary to the Royal Society. In the "Philosophical Transactions" for that year will be found a Latin address by Dr. Juring, in which he anticipates nearly all the conditions which are now considered essential for comparable observations. This appeal did not lead to much being done, and in 1744 another attempt was made by Mr. Roger Pickering, F.R.S., who read before the Royal Society a paper entitled "Scheme of a Diary of the Weather, together with Drafts and Descriptions of Machines subservient thereunto." The Meteorological Society of the Palatinate was established in 1780 under the auspices of the Elector Charles Theodore, who not only gave it the support of his public patronage, but entered with spirit and ability into its pursuits, and furnished it with the means of defraying the expense of instruments of the best construction, which were gratuitously distributed to all parts of Europe, and even to America. One of the first acts of the Association was to write to all the principal universities, scientific academies, and colleges, soliciting their co-operation, and offering to present them with all the necessary instruments, properly verified by standards, and free of expense. The offer was accepted by thirty societies, and the list of distinguished men who undertook to make the observations shows the importance which was attached to the plan and the zeal with which it was promoted in every part of the Continent. In 1823 the first meeting of the Meteorological Society of London was held, and was attended by Luke Howard, Thomas Forster, Dr. Birkbeck, and others. After 1824 the Society languished, but it was never regularly dissolved. Owing to several letters and articles which appeared in Loudon's "Magazine of Natural History," a meeting was held on November 15th, 1836, at which the Society was revived, Mr. W. H. White appointed Secretary, and regular meetings resumed. Application was made to the Royal Society for permission to compare the instruments of the Society with the Royal

Society's standards, and leave was granted on March 13th, 1838. A volume of "Transactions" was published in 1839, and among other articles contains one entitled "Remarks on the Present State of Meteorological Science," by John Ruskin. The cost of the publication of this volume exhausted the funds of the Society, but in 1841 Mr. Gutch undertook personally the pecuniary risk of a new publication entitled the "Quarterly Journal of Meteorology," but this does not appear to have been very successful, owing to the high rates of postage. Shortly after this the Society practically came to an end. On April 3rd, 1850, a meeting of some friends of the science was convened by Dr. Lec at Hartwell, when the British Meteorological Society was established, and Mr. S. C. Whitbread elected President. The first general meeting of the members was not held till March 25th, 1851, but in the meanwhile several important steps had been taken by the Council. Annual reports were published from 1851 to 1861, and since then five volumes of the Proceedings and six volumes of the "Quarterly Journal" have been published. Up to 1858 absolutely nothing had been done towards forming a library, but in 1862 a catalogue was published containing about two hundred titles. In 1876 a new catalogue was issued, which extends to eighty pages, and contains over 1200 entries. On January 27th, 1866, the Society obtained a Royal Charter of Incorporation, and has since been known as "The Meteorological Society." On April 4th, 1872, the Council resolved upon taking a room for an office and for the protection of the library, and appointed Mr. W. Marriott as their Assistant Secretary. The work has now become so great that the Society has been obliged to take an additional room and to engage three computers. The subsequent eight years have been characterised by great progress. A series of second-order stations has been organised, which are systematically inspected, and at which strictly comparable observations are made. On January 1st, 1880, another and larger series of stations—called climatological—was started, at which the observations are less onerous than those at the second-order stations, but at which they are required to be equally accurate. Observations on natural periodical phenomena are also made at many places and discussed yearly by the Rev. T. A. Preston. At the request of the Society a conference has been appointed, consisting of delegates from several other Societies, to prepare accurate instructions respecting the erection of lightning conductors. At the conclusion of the President's address the following gentlemen were elected the Officers and Council for the ensuing year—viz., President, George James Symons, F.R.S. Vice-Presidents, Edward Ernest Dymond; William Ellis, F.R.A.S.; Joseph Henry Gilbert, Ph.D., F.R.S., F.C.S.; Charles Greaves, M.Inst.C.E., F.G.S. Treasurer, Henry Perigal, F.R.A.S. Trustees, Sir Antonio Brady, F.G.S.; Stephen William Silver, F.R.G.S. Secretaries, Robert Henry Scott, M.A., F.R.S., F.G.S.; John William Tripe, M.D., M.R.C.P.E., V.P. Soc. Analysts. Foreign Secretary, John Knox Laughton, M.A., F.R.A.S., F.R.G.S. Council, Edward Douglas Archibald, M.A.; Arthur Brewin, F.R.A.S.; Henry Storks Eaton, M.A.; Rogers Field, B.A., M.Inst.C.E.; Frederic Gaster; Baldwin Latham, M.Inst.C.E., F.G.S.; Robert John Lecky, F.R.A.S.; Edward Mawley; Hon. Francis Albert Rollo Russell, M.A.; Richard Strachan; George Mathews Whipple, B.Sc., F.R.A.S.; Charles Theodore Williams, M.A., M.D., F.R.C.P.

#### MR. HEWITT'S NURSERY, SOLIHULL.

THE railway traveller between Leamington and Birmingham on the Great Western line passes through some of the most interesting of the North Warwickshire scenery, and when he reaches Solihull station, seven miles from Birmingham, he can walk from the platform into "the prettiest little nursery in the provinces," as Mr. Hewitt's "horticultural snuggery" is described by one of the largest home-county nurserymen. It is a pretty nursery. It isn't large, when large is the epithet you would apply to the well-known establishments of the Pauls, Richard Smith & Co., Cranstons, &c., but it is good in every way. The genial and popular proprietor will have everything done well; he is too fond of his craft to allow trouble or expense to stand in the way of doing his best for his favourite plants and flowers.

On my last visit Mr. Hewitt kindly went round the nursery with me, and took me through his nineteen houses. The most showy of these was a new one 50 feet by 12 feet full of Zonal Pelargoniums. How bright it looked that dismal December afternoon! Why are not these Pelargoniums grown more largely by amateurs? The Camellia house next forced my attention, and I was fairly surprised to find such grand specimen plants, such perfectly clean bright foliage (and yet I have seen Mr. William Paul's Camellias at Waltham Cross!) Before the 12th of December upwards of three thousand blooms had been cut in this house. I saw large specimens of the well-known Donckelaari, Lady Hume's Blush, Fimbriata, and the Old White, one tree of this last variety having supplied Mr. Hewitt with upwards of one thousand blooms last season. In one of the three propagating houses Lilics of the Valley were being forced in succession, there being a very great demand for them both as cut flowers and in pots. Another large house is devoted to Primulas, and if you wish to see this flower in its perfection you must go into the neighbourhood of

Birmingham. The indoor fernery there is most lovely; I have never seen elsewhere anything of its kind to approach it in beautiful effect.

But I must now go out of doors and look at the Hollies, for which this nursery is so famous. Here may be seen perhaps one of the best and choicest collection in the provinces as pyramids, standards, and bushes. Of the hardy Conifers I noticed especially *Retinospora plumosa aurea* and *argentea*, *R. obtusa nana aurea*, and last but not least some very valuable specimens of the comparatively recently introduced *Thujopsis dolabrata*. Mr. Hewitt is a lover, and therefore an enthusiastic cultivator, of hardy herbaceous plants, large borders being devoted to *Tritomas*, *Potentillas*, *Phloxes*, *Pyrethrums*, *Delphiniums*, &c. Of *Delphiniums* he has a very large collection. Double Primroses are grown in great quantities for the trade. Roses, too, are largely grown, the flowers being cut in the bud state for button holes, all of which find a ready sale in the Birmingham market. From this little establishment upwards of three thousand bouquets and twenty-two thousand button holes are annually sent. I concluded my inspection by a visit to Mr. Hewitt's house, which is surrounded by noble specimen shrubs, &c. On each side of a straight walk was a ribbon border of evergreens in three rows—at the back *C. Lawsoniana erecta viridis*, centre *Retinospora plumosa*, and in the front *Retinospora plumosa aurea*—and very effective it was.—J. A. W.

#### PITHY CELERY.

I THINK we must look somewhere else for the cause of inferior Celery than in early sowing, but as alluded to by "PRACTITIONER" on page 48, there is a considerable difference in the quality of different varieties. I have grown several of them, but found none equal to what was sent out more than a quarter of a century ago under the name of Cole's Solid Red. I have grown no other for the last twenty years except for trial. It has never been inferior, except three years ago, when it was injured very much by the Celery fly. Out of nearly eight hundred sticks grown each year not one is pithy or runs to seed until late in the spring. The seed is sown in pans the second or third week in February. These are in the early vinery, and the young plants obtained are planted out in the open trench from the 20th to the end of May. They are not earthed-up in the least until the beginning of September, except those required for use at an earlier date. The whole is kept well watered through the summer if the weather is dry, when it is earthed-up. I frequently place some 2-inch drain pipes along the row 2 inches from the plants, leaving an inch open between the ends of each pipe. If the ground is level I place a pipe nearly upright at each end of the row; if on an incline one at the upper end will do. Down this pipe the water is poured, which will go through the openings and supply the whole length of the row. With the above-named variety and even ordinary cultivation, I feel assured that no one will have any pithy Celery.—D. WALKER, *Dunorlan*.

#### NOTES FROM MY GARDEN IN 1880.

##### ROSES.

As the notes which I have given in former years seem to have been acceptable to many of the readers of the Journal—simply, I suppose, as they are the record of one who has to fight against the difficulties consequent on not having a full purse, and who must superintend all the work and do a part of it himself, and not because there is anything extraordinary in his garden or his management—I shall again give my experience.

There is no doubt that in climate and situation we enjoy in this part of England advantages which are denied to many other counties; and although I once envied the greater mildness of Devon and Cornwall, I begin to think that, take it all round, gardening is more pleasant with us. There are things we cannot grow here which they grow in Cornwall; but then when a severe winter comes, as in 1879–80, the destruction which takes place is disheartening in the extreme; while if the more favoured districts of the south-west of Scotland enable gardeners to grow some plants to their great delight and the envy of their neighbours, we must bear in mind that their rainfall is nearly double ours; so that altogether I think we may not unreasonably claim to be the garden of England. Yet all that did not save us in the disastrous season of 1879, the effects of which I have to record in my notices of successes and failures in 1880.

I have already in the pages of the Journal given a general view of the season as it affected Roses and Rose shows throughout the kingdom, but perhaps after all there may be some little interest in the record of my own few hundreds: there is certainly to myself,

as I wish to ask the opinion and advice of my brother rosarians on one point.

In one respect the winter of 1879 was a very disastrous one to me. It played sad havoc with my grand plant of *Rêve d'Or*. All that part of it which faced the north was completely killed, and a large portion on the east wall was also killed. I was afraid that the whole tree would have succumbed to the severe and long-continued frost, but happily it is not so, and it has made a very determined attempt to recover itself; so that I hope before the end of the season it will have filled up a good deal of the vacant space. I have the satisfaction of feeling that it is not likely to be subject to such a severe ordeal again, for we are not likely soon to experience such a winter following such a season. In the same way my plant of *Cloth of Gold* suffered, and certainly more severely; for as the growth is so different the loss of wood is much more serious, in fact there was hardly anything left of it; but here again the tree is alive, and has made shoots 16 to 18 feet in length. I had carefully mulched the roots and stems of both plants, and if this winter had been severe should have matted up the shoots of *Cloth of Gold*, as it is evidently more easily affected by frost than *Rêve d'Or*.

I have been greatly discouraged with regard to my Roses generally. I committed the mistake, which I believe many did, of not pruning their Roses hard enough after so severe a winter, and, deceived by the manner in which they sent forth their shoots, believed that they would do well; but as the summer wore on I found out my mistake. Many died off; and many more, after giving a few good blooms, refused to grow any more. And here came a difficulty against which I have had to contend, and in some years more than in others—I mean orange fungus. It attacked my plants at the blooming season, and by the end of July nearly all the foliage had fallen. Can any of my brethren give me any consolation in this matter? Let me say that the situation of my rosery is quite open; I have no trees anywhere near me; it has all the benefit of light and air, and yet is not very exposed to violent winds; the soil is naturally a light friable loam, but during the past few years I have added a considerable quantity of good sound loam to it, so that it is in fairly good heart now for Roses; I have employed manure freely, but not to the extent that some growers do: and I see nothing in all these conditions that should subject the plants to this disease. If there are, I should like to be told which; and if I can get no information on this point perhaps some kind friend will tell me how to treat the plants when they are affected. The disease seems to come all at once: the under parts become quite orange, and then the whole of the leaf drops off, the slightest touch sending it down. I have seen somewhere a suggestion that the moment it appears the diseased leaves should be picked off, as it is believed to be infectious; but, with me at any rate, it would involve picking off the whole of the foliage. I cannot, therefore, think much of this suggestion. Then something has been said about syringing them with vitriol. I should like very much to know whether this has been known in any case to have stopped the disease. Unlike mildew, it does not seem to be dependant on atmospheric conditions, although it may be my ignorance to suppose that it is not. However, I have told my case, and can only ask for helpful advice.

By-the-by, I see in the "Year Book" that my brother Secretary mentions the fact that at Hereford he saw at the end of September at Messrs. Cranston & Co.'s nearly the whole of their large "stock of dwarfs on the Manetti had not only ceased flowering, but that much of the foliage had turned quite yellow, and in some instances many leaves had already fallen." This looked suspiciously like my enemy's work, only that he adds that it was not the case with those on the seedling Briar; but in my garden I have not traced that any difference existed, the stock seeming in no way to ward off or induce the attack.

I have already given my opinion on the new Roses as far as my experience went, and I shall but repeat what I have said in the "Year Book" concerning them. As far as English Roses are concerned I think the order of merit runs thus—Duke of Teck, Harrison Weir, Duchess of Bedford; while among the more recent French Roses Louis Doré, Charles Baltet, Gaston Levêque, Madame Eugène Verdier, Comtesse de Choiseuil, Léon Renault, Paul Jamin, Souvenir de Victor Verdier, William Koëlle, Préfet Lurberg, Jules Chrétien II., Jules Finger, Gloire de Bourg la Reine, Baron Taylor, Comtesse de Mormart, Catherine Soupert, Madame Oswald de Kerchove, Madame Lambard (Tea), and Innocente Pirola may be regarded as containing the most desirable. It may be that some of them may not retain their present position, and that some outsider may appear to oust some of them.

As so many of my Roses were crippled, and they were to be had at so reasonable a rate, I have discarded a large number of

wounded heroes and supplied their places with recruits. I have not, however, put them aside altogether, but have placed them in a sort of Chelsea Hospital, where, strange to say, although there is apparently no difference in the soil, they seem to recover themselves in a very wonderful way.—D., Deal.

### VARIATION IN TOMATO FRUITS.

HAVING noticed on page 25 that Mr. Iggulden has referred to the variation of Vick's Criterion as grown here, I consider the characteristic of the variety very marked in that respect; and in my experience of it, it is more subject to variation than any other variety I am acquainted with. The first season it was sent out I had an opportunity of seeing at Hawkstone many plants fruiting in 10-inch pots on the south side of a plant house outside. The stems were about 3 feet in height, very strong, and the crop a heavy one, with the fruit just ripening from the bottom half way up. I must confess I was somewhat surprised at seeing so many forms of fruits upon Vick's Criterion. Upon close examination no good judge could have passed the corrugated fruits for others than the variety mentioned. The colour, which is so distinct, was the same as in the smooth fruits. A number of cuttings of Vick's Criterion were rooted and planted in August last from which to obtain a crop of fruit during the winter here. The first bunches that set took their own course, but the fruits were all smooth. When the plants attained 3 or 4 feet in height they grew very strongly and produced enormous trusses of bloom, which as autumn approached were fertilised with pollen from the small flowers at the end of the truss, and nearly all the first fruits were corrugated, and several remain at the present time. Since the plants have become less vigorous the fruits towards the points are all smooth. Propagation by cuttings makes no difference after the plants attain strength, and the stronger they grow the more corrugated fruits they produce.

Two years ago I grew a number of the variety Green Gage, but only the strongest plants produced slightly corrugated fruits. Seed was saved from these fruits, but the plants raised from all produced smooth fruits. I think Mr. Iggulden right in stating that it would be unwise to attempt to show the two forms from the same plant or plants, and so run the risk of being disqualified.—WM. BARDNEY.

### MANETTIAS.

MANETTIA is not a large genus, nor are the few species included in it so beautiful as some of its allies in the great order Rubiaceæ, which yields us so many handsome plants; yet there are at least four species that would well repay for more extended cultivation—namely, those briefly described below. Except in the largest collections of plants, perhaps it would be scarcely possible to find them all grown in one garden, but in many one or possibly two are represented, and usually highly appreciated both by gardener and employer. They are of climbing habit, but differ considerably in the size they attain, some being well adapted for planting out in the stove and training up pillars and roofs; others are better suited for culture in pots either in the stove or greenhouse. With regard, however, to the temperature they need, I have found that they grow and flower more freely in what is ordinarily termed an intermediate house—that is, where the temperature is not so high as that of a stove nor so low as a greenhouse, but where there is more abundant atmospheric moisture than in the last-named structure. *M. bicolor* certainly thrives satisfactorily in a greenhouse when in flower, but it requires warmer quarters in which to complete its growth. As to soil, Manettias are not very fastidious. I have found them succeed in a compost of fibrous loam, leaf soil or peat, and sand, with a small amount of well-decayed manure when grown in pots, and under the same circumstances very weak liquid manure may be occasionally supplied advantageously. The usual care must be exercised in providing good drainage, for though not particularly liable to suffer from neglect in that respect, they, like all other plants, give greater satisfaction when superfluous moisture is not allowed to accumulate around the roots. The species of very strong growth need a little judicious pruning, but their requirements in that or any other point are not troublesome, and few in cultivating the plants will encounter difficulties of much importance, or such that a little skill will not overcome.

*Manettia bicolor*.—Though the flowers of this species are not individually so large or brilliant as those produced by the other forms, they amply compensate for their deficiency in size by the abundance in which they are borne and the distinctness of their colours; and further, the adaptability of the plant to culture in pots renders it of considerable value for decorative purposes at

the present season and during spring. It has slender graceful stems, and lanceolate, tapering, bright green, opposite leaves, from the axils of which the tubular flowers are produced. These characters are shown in fig. 14, except that, as it represents a

Fig. 14.—*Manettia bicolor*.

lateral flowering spray, the leaves are smaller than upon the main stems. The corolla is a bright scarlet at the lower portion and yellow towards the apical part of the tube, the four small lobes being of the same tint. When the plant is grown in a pot a trellis of some form must be provided, and over this the branches may be trained so closely that it will appear a mass of foliage and flowers. A balloon-shaped trellis is the most suitable, and neat specimen plants can be obtained in 32 or 24-size pots. In the latter size I have had examples about a yard high that have attracted considerable attention when placed in a greenhouse during the early months of the year. A succession of flowers may be easily obtained by forwarding some plants in additional heat

and retarding others. Cuttings of the young shoots strike readily in fine sandy soil, the pots being plunged in bottom heat.

The history of the species is brief. It is a native of the Organ Mountains, Rio Janeiro, where the noted botanical traveller Mr. William Lobb found it, and from him Messrs. Veitch of Exeter obtained their stock nearly forty years since.

*M. cordifolia*.—This is of slightly taller habit than *M. bicolor*, but may be also grown in pots, though it is more frequently employed as a climber in stoves or slightly cooler houses. It is very distinct from the one last described both in the form and colour of the flowers, which are also larger, but are produced in a similar way; the corolla bright orange-scarlet in colour, trumpet-shaped, with very small revolute teeth; and the leaves are cordate at the base, tapering, with very short footstalks. The plant blooms at different times from December to early summer months, and is useful for cutting, as the flowers are freely and successively produced. In its native home, Brazil, it is said to abound in the borders of forests, where it trails luxuriantly over small trees and shrubs, appearing very beautiful when in flower. It was there discovered by Mr. Tweedie, who forwarded seeds to a celebrated gentleman at Edinburgh, in whose collection flowers were first produced in the year 1832. The species is noteworthy as being the only one possessing any economic properties, for in Brazil the powdered bark of the root is considered as a highly beneficial medicine in dropsy and dysentery. It is also used as an emetic.

*M. micans*.—Unquestionably one of the most beautiful species when well grown, either in pots or planted out, in a stove or a moderately warm conservatory. In pots it may be trained according to the grower's taste, but, as mentioned under *M. bicolor*, a balloon trellis is the most generally approved form. It is very free in growth and flowering, bearing abundant panicles of rich orange-coloured flowers, similar in shape to *M. cordifolia*, but with comparatively broad lobes of a yellow tint. The leaves are heart-shaped at the base, with a bright shining green upper surface, and

have very short petioles, which are sometimes quite absent. In cultivation the flowers usually appear in the latter months of the year, a period when they are most acceptable; indeed, it cannot be too highly recommended both as a decorative plant and for affording supplies of useful flowers that can be employed to great advantage in all the numerous modes of floral decoration, as they combine most gracefully with other flowers and Ferns. The public are indebted to Messrs. Veitch of Chelsea for the introduction of this plant, as that firm obtained it from Peru about twenty years ago. It is found growing in woods at a considerable elevation above the sea level, and there attains the height of 20 feet or more.

*M. coccinea*.—This is not so well known in cultivation as those already described, though it was, I believe, the first introduced to this country. Possibly that is due to the lesser degree of brilliancy possessed by the flowers, though they are sufficiently attractive to render the plant worth growing. It thrives well in a stove, and trained up pillars its flowers appear to the best advantage, as the plant is of strong growth. It has flexible tough stems, elliptical leaves, and tubular corollas, which in the specimens that have come under my notice were of a rosy pink tint, deeper in the lobes. The calyx is peculiar, consisting of eight to ten linear recurved divisions, which impart a distinct appearance to the flowers. The latter are borne on small lateral branches, and are continuously produced during a period of two months or more in the summer or autumn. Seeds from Trinidad were first sent to the Chelsea Botanic Garden in 1823.—L. C.

AT the annual meeting of the Committee of the HORTICULTURAL CLUB, held at their Club House on the 18th inst., a satisfactory statement of the financial condition of the Club was presented, and a further sum was directed to be invested. Messrs. G. P. Hawtrey, Charles F. Hore, and G. Smith were elected members of the Committee in place of the three retiring members. The annual dinner took place afterwards, and was very fully attended, John Lee, Esq., in the chair. Amongst those present were General Puckle, Rev. G. Henslow, Rev. H. H. D'Ombrian, Dr. Hogg; Messrs. Bull, G. Deal, Hawtrey, Killiek, Laing, G. Smith, C. P. Wheatstone, Harry J. Veitch, J. B. Haywood, J. D. Pawle, H. Porteous Oakes, James Cutbush, Robert Osborn, W. Lee, H. Wood Ingram, and Wollaston. A pleasant evening was spent, and much satisfaction expressed with the arrangements of the Club.

— MR. W. SOWERBY informs us that the ROYAL BOTANIC SOCIETY will, as usual, hold four exhibitions during the present year. The Spring Shows will take place on March 30th and April the 27th, and the Summer Shows on May the 25th and June the 22nd. The Evening Fête will be held on June the 15th. Lectures will be delivered in the Garden on Fridays at 4 P.M., from May the 6th to June the 24th.

— AT the annual meeting of the WIMBLEDON HORTICULTURAL SOCIETY held last Friday, Mr. H. A. Rolt, of Maud Villa, Gladstone Road, Wimbledon, was appointed Secretary of the Society in place of Mr. P. Appleby, who resigned that office.

— WE understand, that in consequence of the increased DEMAND FOR FLOWERS AND PLANTS AT WELBECK ABBEY, the seat of the Duke of Portland, Mr. Carr, the gardener, has been obliged to convert several of the Peach houses and late vineries into plant stoves. Messrs. J. Weeks & Co. of Chelsea have received instructions to put down one of their largest duplex boilers, and to make the necessary additions to the piping in the houses.

— MESSRS. CARTER & Co. announce that they intend offering the following valuable cash prizes for their NEW PEAS AND OTHER VEGETABLES at the undermentioned meetings of the Royal Hor-

ticultural Society during 1881:—At the Great Summer Show, June 28th, 1881, one dish (fifty pods) Carter's Stratagem Pea, one dish (fifty pods) Carter's Telephone Pea, one dish (fifty pods) Carter's Pride of the Market Pea, one dish (fifty pods) Carter's Telegraph Pea; first prize, £5; second, £3; third, £2; fourth, £1; fifth, 10s. 6d. At the Society's meeting on December 13th, 1881, for the best collection of twelve dishes of vegetables (without restriction as to varieties), to include twelve Onions, twelve Turnips, three Cauliflowers, three Celery, fifty Brussels Sprouts, twelve kidney Potatoes, twelve Carrots, twelve Parsnips, six Leeks, three red Beet, twelve round Potatoes, one dish, open; first prize, £5; second, £3; third, £1 10s.; fourth, £1; fifth, 10s.; sixth, 7s. 6d.

— WE are informed that a meeting of the NORTHAMPTON CHRYSANTHEMUM SOCIETY was recently held to present to the Hon. Secretary, Mr. E. Draper, a testimonial in recognition of the valuable services he has rendered the Society during the many years he has held that office. The testimonial consisted of an elegant gold lever watch, chain, and seal, with an appropriate inscription. Mr. G. Gulliver presided, Mr. B. Johnson took the vice-chair, and a number of gentlemen were present, many of whom expressed their cordial gratification at the means adopted of intimating the general esteem for their persevering and indefatigable Secretary. Mr. Draper acknowledged the receipt of the testimonial in suitable terms.

— WE have received from Messrs. W. Stewart & Co., Holborn Viaduct, E.C., a copy of a small work by Mr. D. Houston, entitled "PRACTICAL BOTANY FOR ELEMENTARY STUDENTS," which appears to be accurately and lucidly written, and well suited for the young of both sexes who are commencing the study of botany with the aid of a teacher. Descriptions are given of some of the commonest wild plants as types of the larger natural orders, with general indications of their chief properties.

— A CORRESPONDENT sends the following letter—"In Messrs. Suttons' nursery I recently noticed a large house filled with CYCLAMEN READING GEM, for which a first-class certificate was awarded by the Royal Horticultural Society. It is a compact yet shrubby variety, with beautifully marbled foliage. The flowers are large, the petals remarkably broad and of great substance, colour white with a deep crimson base. It gives promise of being an easily grown and very serviceable variety. There are several other good varieties, some of the pure whites being particularly promising on account of their sturdiness and the size of their blooms. Much attention is paid to securing handsome foliage and sturdy flower stems, in addition to large sweetly-scented blooms."

— THE following are amongst some of the recent APPOINTMENTS OF GARDENERS:—Mr. J. Heath, Hiteham Grange, Maidenhead, has been appointed gardener to A. Longsdon, Esq., Fairfield, Upper Denmark Hill; Mr. G. Richards, late foreman at Gunnersbury Park, Acton, becomes gardener to A. Ussher, Esq., Villa Selvosa, Cannes; Mr. C. Gregory, Terlings Park, Harlow, takes charge of the gardens of G. B. Tipping, Esq., Coombe Lodge, Kingston Hill; Mr. J. Brightman, late foreman at Peterborough House, Fulham, has been appointed gardener to J. Carter Houghton, Esq., 20, Devonshire Place, London; Mr. J. Davis, Drayeot House, Fulham, succeeds Mr. Roe as gardener to J. S. Crawley, Esq., Stockwood Park, Luton; and Mr. J. Foster, Solna, Roehampton, becomes gardener to W. Kemp, Esq., Burnt House, Chigwell.

— WE learn that the magnificent FLORAL DECORATIONS at the marriage of Mr. Leopold De Rothschild and Mdle. Marie Perugia last week, which were so glowingly described in the daily papers, were supplied by Messrs. Veitch & Son of Chelsea, who executed all the arrangements with admirable taste.

— A CORRESPONDENT in Ipswich informs us that a number of gentlemen recently held a meeting in that town to consider the best mode of encouraging the culture of Roses in the district. After some discussion it was resolved that a Society should be formed to consist of amateur and professional Rose-growers, and to be named the EAST ANGLIAN ROSE SOCIETY, which will obtain its members from the counties Norfolk, Suffolk, and Essex. It is intended to hold an exhibition every year in one of these counties; the first to be held in connection with the summer Show of the Ipswich Horticultural Association. The following gentlemen were appointed to constitute the Committee.—The Rev. Foster Melliar, Tostock Rectory; Mr. W. Nicholl, Hengrave; and Mr. D. T. Fish, Hardwick House, Bury St. Edmunds; the Rev. H. Frere, Burston Rectory; and the Rev. Page Roberts, Scole Rectory, Diss; the Rev. Hugh A. Berners, Harkstead Rectory, Ipswich; and Mr. B. R. Cant, Colchester; the three last named being Hon. Secretaries *pro tem.*, to whom all inquiries or subscriptions should be addressed.

— AT the annual meeting of the SCOTTISH SEED AND NURSERY TRADE ASSOCIATION recently held in Edinburgh, Mr. Downie presiding, the report read by the Secretary, Mr. David Hunter, stated that the Society now includes forty-two members, there being the substantial balance of £57 19s. to the credit of the Association. It was also announced the prize of £5 offered for the best essay on the means of discovering adulteration in Clover seeds had not induced any competition. Mr. R. T. Macintosh was appointed President for the present year, Mr. James Hunter Vice-President, and Mr. David Hunter Secretary and Treasurer.

— A VETERAN gardener, WILLIAM SHAW of Tuebrook, near Liverpool, died on the 19th inst. at the age of eighty-six years. Long before his death Mr. Shaw became a wealthy man in consequence of having "taken care of the pence" in his youthful days, and investing his savings judiciously. Mr. Shaw was widely known and esteemed by the gardeners of the district in which he lived so long.

— WE learn that the DUNDEE HORTICULTURAL SOCIETY will hold a grand floral fête on the 1st, 2nd, and 3rd of September this year, when upwards of £300 will be offered in prize money. Competition open to the United Kingdom. Schedules may be had on application to Mr. D. P. Scott, Secretary, 9, Renny Place, Broughty Ferry, or Mr. John Miln, Treasurer, Euclid Crescent, Dundee.

— THE chief event in the horticultural exhibiting world in the present year will probably be the INTERNATIONAL EXHIBITION TO BE HELD AT MANCHESTER on the 24th to 27th of August; and the schedule, which is now issued, shows that from the number of liberal prizes offered no efforts have been spared to induce keen competition and an extensive display. Two hundred and thirty-seven classes are enumerated, of which those devoted to fruits—namely seventy-three, form a large comparative proportion, vegetables and plants being also well provided for; while cut flowers, bouquets, table decorations, implements, and cottagers' productions are all likely to be well represented judging from the prizes offered. Special prizes of considerable value are also offered for plants, vegetables, and fruits by the Veitch memorial trustees, the General Horticultural Company (John Wills) limited, and Messrs. Sutton & Sons; Dickson, Brown & Tait; Dickson & Robinson, and G. & W. Yates. Some of the chief classes in the several divisions are the following:—Fruits—for collections of fifteen and twelve kinds, £20, £15, and £10; £15, £10, and £5 as first, second, and third prizes respectively in the two classes; ten varieties of Grapes, one bunch each, £12, £8, and £5. Many other liberal prizes are also offered for Grapes, Peaches, Nectarines, Pine Apples, Pears, Apples, &c. One section of this class is confined to fruiterers, and another to fruits of foreign growth.

In the latter France, Italy, Germany, Holland, Belgium, America, Turkey, and Egypt being represented. The most important special prizes for fruits are those offered by the General Horticultural Company—namely, two of thirty guineas, and two of twenty guineas each. Among vegetables the highest prize is £10 for twenty varieties, while the principal amounts in the plant classes are £20, £15, and £10 for twenty miscellaneous plants. The entries close on August the 14th, and all communications should be addressed to Mr. Bruce Findlay, Royal Botanical Gardens, Manchester.

— THE SHEFFIELD FLORAL AND HORTICULTURAL SOCIETY is the designation of a new organisation that has just been established by some of the leading gardeners of the district. The objects of the Society, which are in all respects commendable, cannot be better described than by quoting from the rules:—"1, The mutual improvement of its members, and advancement of floriculture and horticulture, by exhibitions of plants, flowers, fruits, and vegetables; 2, periodical meetings for the purpose of reading essays, and for discussions upon any subject that shall bear directly or indirectly upon the science of gardening, and that shall be considered to increase the skill and knowledge of either the professional or amateur gardener in horticultural pursuits; 3, also the delivery of scientific lectures on any subject that may be deemed essential in carrying out the above objects." Monthly exhibitions of plants, fruit, and vegetables will be held by the members, and larger shows as may be determined upon. A great amount of support has been accorded to the Society by the local gentry, and the number of members is increasing daily. Amongst the officers appointed are Mr. Haigh, Treasurer; Messrs. Udale and Eadon, Trustees; Mr. B. Simonite, Curator; and Messrs. W. K. Woodcock and J. F. Hanson, Hon. Secretaries. An excellent Committee has also been formed for conducting the affairs of the Society, which promises to become a prosperous one.

— It is announced that M. Ed. André has ceased to be the editor of "L'Illustration Horticole."

— FLORISTS' SOCIETIES.—The annual general meeting of the members of the National Auricula (Northern Section), Royal National Tulip, and National Carnation and Picotee (Northern Section) Societies will be held at the old "Bull's Head" (off the Market Place), Manchester, on Wednesday, February 2nd, 1881, at three o'clock, P.M. Business—To arrange date of this year's exhibitions, schedule of prizes, plan of judging, and any other matter and work connected with the management of the National Florists' Societies, Northern Section. The attendance of the members of the above Societies is earnestly requested.—S. BARLOW, *Hon. Sec. Royal Nat. Tulip Society, Stakehill House, Chadderton, Manchester*; F. D. HORNER, *Hon. Sec. National Auricula, and Carnation and Picotee Societies (Northern Sections), Kirkby Malzeard, Ripon.*

### THE FROST.

WHEN a sheep is roasted whole on the Thames, as was the case last Saturday near Twickenham, and when preparations have been made for roasting a bullock in a similar manner, sufficient proof is afforded of the exceptional severity of the weather. The temperature near London has not been so low during the past few days as previously, but there are very slight, if any, signs of a thaw. The snow lies in huge mounds and ridges, and some idea may be formed of its bulk from the statement of Sir J. McGarel Hogg in the House of Commons on Monday night, that a depth of 6 inches of snow over the metropolitan district of 117 square miles is computed to weigh eight millions and three-quarters of tons. We have received a great number of letters relative to the weather, and we can only make brief extracts from some of them to show its character in various districts. *Devonshire*.—Writing from Sidmouth, "E. D. B." observes that the snow is about a foot in depth, and the lowest temperature has been 17°. A week previous to the storm Rhododendrons, Snowdrops, and Primroses were flowering out of doors. *Sussex*.—Mr. W. Jordan writing from Silgate, Crawley, Sussex, observes, "The weather here still continues very severe. The lowest temperature experienced up to

the present time was on the 21st inst., when at 8.45 P.M. a thermometer 4 feet from the ground registered 4°. *Norfolk*.—Mr. J. Batters, The Gardens, Gillingham Hall, states that the recent storm was exceptionally severe in that locality; the lowest temperature was 3° Fahr. on the 25th inst. *Bedfordshire*.—Mr. Allis, Old Warden Gardens, states that the gale was very severe on the 18th inst., much damage having been done to the fine trees in the park, Scotch Firs 70 feet high having been completely uprooted. On the 21st inst. the minimum temperature registered was 4°. *Warwickshire*.—At Yardley Wood Vicarage near Birmingham temperatures of 5° and 2° have been registered, and our correspondent is anxious about its effects on his Tea Roses. *Northamptonshire*.—From Broughton House Gardens, Kettering, Mr. F. Jones writes, stating the lowest temperatures were observed on the 14th, 19th, and 21st insts. 3° registered on the first, and 2° on each of the other dates. *Herefordshire*.—A correspondent writes that the lowest temperature in the neighbourhood of Hereford was on the 22nd inst., when the minimum was 3°, but on the following day it rose to 29°, with the appearance of a thaw. *Lincolnshire*.—“A. M. B.” writes:—“The domestic inconvenience from the frost has been considerable everywhere; all provisions requiring to be kept as near the fire as possible. Eggs freezing and cracking in the nest, new milk is frozen in transit; and although the thermometer may not have registered so many degrees of frost as last winter, the cold would appear to have been more generally unbearable.” *Cheshire*.—Mr. C. J. Day of Rawton, Chester, informs us that on the 15th inst. the temperature fell to 1°, but that in less elevated positions the temperature has fallen below zero. *Lancashire*.—Mr. W. Bardney, Norris Green, Liverpool, writes that the weather in that neighbourhood has been intensely cold, the temperature having fallen to zero, with a keen wind drifting the snow 6 and 8 feet deep. *Yorkshire*.—Mr. G. Abbey, Grinkle Park Gardens, states that in his position, 540 feet above sea level, the cold has not been so severe as in lower districts, but a temperature of 3° has been recorded on one occasion recently. *Durham*.—From Mr. B. Cowan, South Shields, we learn the lowest temperature since our last issue has been 22°, with a north-east wind. *Glamorganshire*.—Mr. J. Muir, at Margam Park, records 12° as the lowest in his locality, with a cold wind, which will, he thinks, “keep the fruit buds in their proper season.”

In Scotland the frost has been very severe. Mr. R. W. Brotherston states that the snow is an average depth of 16½ inches, the following remarkably low temperatures having been registered—namely, 3°, 9°, and even 22° below zero, the latter recorded at Blackadder House. Mr. David Thomson, Drumlairig, Dumfriesshire, writes:—“From January the 8th to the 17th inst. inclusive we have had a mean of 24½° of frost each day. The lowest temperature here was 2° below zero on the 17th inst, but on Tweedside 2° and 14° below zero have been registered.” Mr. James Dickson, Arkleton, the same county as the above, gives 17° below zero on the 16th inst. as the lowest temperature; while Mr. J. Forbes of the Buccleuch Nurseries, Hawick, states 4° below zero was registered there on the 17th inst.

In Ireland the weather has also been severe in some districts, the lowest recorded in Tipperary being 10° Fahr., the ice on the lakes being upwards of 14 inches in thickness.

#### GARDEN CROPS IN WEST CORNWALL.

IN the first number of the Journal for the present year “WILTSHIRE RECTOR” gives some very good suggestions on the “The Future of Gardening” and its crops, although he advocates the culture of Onions more extensively, which is not gaining favour with growers, especially our Cornish market growers. The area devoted to them is rapidly decreasing every year, and this year the price of seed is so high it is obvious that still less will be sown.

Broccoli and early Potatoes are the principal crops in Cornwall. Broccoli are at the time of my writing (January 21st) the greater part buried in snow. Parsley has been a profitable crop for the past two years, especially at Scilly, where one man made £20 of the produce from 2 ozs. of seed. Asparagus is also remunerative when well grown and in a sandy soil, and sent to the markets tied in neat bundles. Connover’s Colossal Asparagus is the best. Radishes are somewhat extensively grown, principally the Long Scarlet. The seed is sown in autumn, and the price will no doubt be good this severe weather. The encouraging remarks to gardeners and farmers generally on page 1 were, I am sure, read by many with great interest, and no less hearty good wishes to “WILTSHIRE RECTOR.”—W. ROBERTS, *Penzance*.

#### SCIENCE IN HORTICULTURE.

I AM what my *nom de plume* indicates, a gardener in a single-handed situation, and I want to say something about what appeared on page 24 of the *Journal of Horticulture* under the above heading. As I am only a recent reader of the Journal I do not know who “D., Deal,” is, and as I live presumably hundreds of miles distant from him, it does not much matter; but if I may be allowed to guess, I guess that he is a clergyman, for I have heard some clergymen speak about science in the way

“D., Deal,” does. I have thought it necessary to say that I am a gardener to prevent “D., Deal,” from supposing that I am some scientist who has taken up his pen to defend science; and yet the statement is hardly necessary either, for no scientific man would do more, after reading such a paper, than pray for the enlightenment of all who hold such views as are there expressed.

Now, although I do not think that scientific men would do more than pass such an article as the one referred to with a smile, practical men, like your humble servant, who have derived no small benefit from the teachings of scientific men, are somewhat concerned about the influence of such writings, for young men who may desire to add a little science to their other attainments may think scientific knowledge of little value after reading such an article. To such we would say, “Get wisdom, get understanding;” in other words, learn as much science as possible, and be sure you will reap benefit therefrom, besides being able to laugh heartily when anybody talks about science à la “D., Deal.”

Having said so much by way of introduction, allow me to say something about (I can scarcely say in reply to) what “D., Deal,” says. First, the Potatoes. What scientific man is to bear the odium of what he says, or implies, about change of soil in Potato cultivation? Scientific men have pointed out, and practice has proved them right, that on ordinary soil under ordinary cultivation a rotation of crops is a good practice, because no two crops require the same matters out of the soil or out of the manure. Wheat or Cabbages may leave the soil too poor to grow another crop of Wheat or Cabbage, but good enough to grow a crop of Potatoes, because Potatoes do not require the same kind of nourishment as Wheat or Cabbage: therefore a rotation of crops is sound in principle, hence good in practice. Again, scientific men have proved that Potatoes, or anything else—Gladioli for instance—will thrive on the same soil as long as the cultivator gives (ignorantly or knowingly) to the soil what the crop removes, or, if naturally the soil possesses an inexhaustible supply, of what is needed. Few soils are fertile enough for this, but very many cottagers’ manure possesses just the required fertilising qualities which are needed. The ash heap of those cottagers whose fuel is wood chiefly, along with a very little ordinary manure, contain all that Potatoes want. Again, it is a scientific—that is to say proved—fact that some varieties of Potatoes withstand disease even on unfavourable soils better than other varieties on favourable ones. This one fact is of itself quite enough to account for the state of matters chronicled by “D., Deal.”

I will say nothing on the zinc and copper affair, and think it would have been as well if your correspondent had not said anything about it either. Then it seems that “science” is to be blamed because “D., Deal,” like hundreds more, has been led astray by the popular but unscientific delusion that porous pots were better for plant-cultivation than non-porous pots; indeed, facts are just the opposite of what “D., Deal,” implies them to be, for for years scientific (in the strictest sense of the term) gardeners have proved that the old idea, although popular, was only a delusion; and although “D., Deal,” may justly blame those who “impressed the unscientific delusion on him from his earliest days of horticulture,” he may as reasonably blame the man in the moon for it as science. Science has proved for us that the only difference between ordinary pots and glazed ones is that the ordinary pots get very dirty in a short time, while the glazed pots remain clean. The dirt renders the most porous pot as non-porous as the glazed ones, and we must in justice thank science for substituting clean pots in the room of dirty ones. A dirty pot is worse every way than a clean although glazed one.

Again, “D., Deal,” advertises the fact that Mr. Bull’s *Sarracénias* are dead, and that “blue-bottle and other flies” are (or were) in the dead pitchers. “D., Deal,” evidently knows nothing of the cultivation of these plants, otherwise he would have known that the mere presence of flies could not account for their state; and if he considers that such a want of knowledge, not only of science, but of ordinary practical gardening, is a sufficient answer to the teachings of young Mr. Darwin and others on the carnivorousness of some plants, we fear he will stand alone. If your correspondent wishes to prove by respectable evidence that no plants whatever are capable of catching and feeding on insects, he will have to *do* (not write) a great deal more than merely state that *So-and-so’s Sarracénias* are dead and yet flies are in their pitchers. Such statements will not count for anything even with ordinary people, far less with men of science.

I really do not know what to say about flies being “diet” for *Ericas*. The only unfortunate thing likely to happen is that some other anti-science party will carry the words in his mind and some day preach a sermon on the text, and say that the assertion was made by some noted scientific man! Thus Tyndall was blamed for asserting that the first of living forms were shot to

the earth from some imaginary planet; thus Darwin was blamed for saying that man "sporting" from the monkey; and thus ignorant persons who believe in spontaneous generation quote Huxley(!) in support of their ridiculous views.

I might have replied at more length, but 1, it is hardly worth while, and 2, I fear to trespass on your space. In the meantime I would urge young gardeners to study those sciences which bear on their profession, such as botany, and more especially physiological botany; geology, and chemistry, more especially agricultural chemistry. The great majority of men who read, study science in some of its branches now-a-days, and we think it a pity that all clergymen should not. It is certain that even clever men who try to ridicule what they know nothing of only make them-

selves ridiculous. Science is not what people in general think, and it certainly is not what it is represented to be by "D., Deal." Observation becomes scientific when it becomes accurate and painstaking, and we become scientific men when we are thus accurate in our observations. Science does not spin theories merely; it ascertains facts. True enough, ridiculous theories have been spun and science been burdened with the name of them, but science is not to blame for the fancies and vagaries of those who rave in her name.—SINGLE-HANDED.

#### PEAR DURONDEAU.

As a late autumn Pear this is one of the finest. In size, colour,

Fig. 15.—DURONDEAU.

and quality it is meritorious, and a dish of well-grown specimens is not easily surpassed on the exhibition table. The finest fruit—especially in colour, which is sometimes very brilliant—is obtained from trees on walls having a good aspect; but excellent produce is gathered from pyramid and espalier trees in good situations. In the north it does not colour so well as in the southern counties; nevertheless it is a hardy variety, and a good if not a heavy bearer. A fine dish is imposing on the dessert table, and those who grow Pears for exhibition should include it in their collections. The "Fruit Manual" description of this Pear is as follows:—

"Fruit large and handsome, regularly formed; obtuse pyriform, and small at the stalk. Skin shining, as if varnished, on the side next the sun, where it is of a lively crimson, marked with broken streaks of darker crimson, and covered with large grey russet dots; on the shaded side it is yellow, with a thin crust of cinnamon

russet, and large russet dots. Eye small and open, set in a rather deep cavity. Stalk an inch long, very slender, and inserted on the end of the fruit. Flesh very tender, melting, and very juicy, sweet, rich, and delicious. A first-rate and beautiful Pear; ripe in the end of October and beginning of November.

"The original tree exists in the garden of the late M. Durondeau, at the village of Tongre-Notre-Dame, near Ath, in Belgium."

#### ZONAL PELARGONIUMS FOR WINTER—GUILLON MANGILLI.

"J. D." at page 48 asks for information respecting this semi-double Zonal, which in my opinion is one of the most distinct in colour and the freest bloomers of all the semi-double varieties. I always understood it was one of M. Lemoine's seedlings, as he

was one of the first of the continental raisers to undertake the dwarf or Tom Thumb type of doubles. I sent it to Chiswick with some of my own varieties, but was not aware that I received a certificate for it. Guillon Mangilli I found one of the best of winter bloomers, the colour being at that period a distinct purple tinted violet. It has long been appreciated in the United States for its good qualities. I had several fine seedlings from it with broader petals, which passed into the hands of my friend Mr. Gilbert, but I never learned whether anything came of them; but when I was a raiser of double Pelargoniums, the strong-habited type with coarse foliage and trusses, such as Gloire de Nancy, were in vogue, and the dwarf semi-doubles, which are so valuable for winter flowering, and which I believe I was one of the first to introduce, were quite unappreciated. Doubtless this arose from the desire of most growers to obtain satisfactory results from their growth out of doors, which the climate of England renders quite impossible. I have, however, seen the best effects produced from the growth of doubles and semi-doubles in the open air with Mr. Pond and others in Jersey.—T. LAXTON.

HAVING observed several inquiries respecting the raiser of the above Zonal, we beg to state that it was raised by Mons. V. Lemoine of Nancy, and distributed in this country in 1875. At that time it was considered a good variety, but new kinds of every year since have been remarkable for their dwarfness and depth of colour. In looking through a house of each double and single varieties it is surprising to observe the difference, some varieties being quite three to six shades deeper than Guillon Mangilli, and it is on this account that it is not found in trade catalogues. Its growth is long and at times straggling, and the pips thin. We discarded it in 1879. Other varieties we find much better not only in habit but in the flowers, more free, a higher tone of colour, and with better rosette-shaped pips. So fine are the doubles that we find by keeping 3° to 5° more of heat in the house where they are situated that they bloom equally as well as the singles during the winter; and although they cannot be compared to the single varieties for brilliancy of colour, yet for cut flowers and withstanding the rough usage they sometimes receive in travelling they are far preferable; in fact, we have no flower to equal them during the winter.—H. CANNELL, JUN.

SINCE Mr. Taylor's article in the Journal on the value of Guillon Mangilli as a winter-flowering Pelargonium, it has naturally excited the attention of many who have a demand for flowers in winter. I have Guillon Mangilli, and another under the name of Jules Mangollen, that are so near alike that I cannot tell one from the other. Both are equally good in the winter, and the flowers opened well in a temperature of 40° Fahr. this year. If mine is the true variety, I would advise those who have one variety not to trouble about getting the other.

My mode of treatment is, as soon as other flowers are plentiful in spring, to cut down the best winter-flowering varieties and put the cuttings singly in small 60's, in a compost of sandy loam three parts, well-decayed manure one part, a little silver sand, and charcoal broken to the size of a small pea. The charcoal dust caused by breaking is placed in with it. The cuttings are pressed rather firmly in. They are generally placed in the cool vinery or cold pit, as they strike well there, and are better than when struck in too much heat. They are much better kept sturdy for winter flowering. As soon as they are well rooted they are shifted into 5-inch pots. A little bone dust is added this time to the compost, and they are placed in a frame or cold pit and kept rather close for a few days, after which the lights are drawn off except in wet weather. All the flowers are kept off as soon as they are seen. It is very rare that they need stopping more than once. Sometimes the old plants are potted-on for winter, but I like the young plants best. Madame Ballet and Wonderful are the next best doubles I have for winter. Good single varieties for the same purpose are Aphrodite, Aida, Placchi, Titania (Pearson's), John Gibbons, Mrs. Hetley, and Mrs. Leavers.—J. L.

[We have had other letters in reference to the variety "Guillon Mangilli," but it would be unfair to nurserymen generally to publish them. The only proper course is for those who have plants for sale to advertise them.—EDS.]

#### STRAWBERRY FARMING.

(Continued from page 23.)

SOIL.—I have just been looking over a list of Strawberries containing the names of nearly five hundred different varieties that have been produced and grown during the present century. Doubtless each of these has been in its day the boast and pet of its raiser, and probably most of them have, even in good faith,

been warranted the best croppers out. Probably most of them have also proved at some time disappointing to over-expectant gardeners, owing mainly to the soil and the variety having been improperly matched. I do not know any kind of fruit the varieties of which are so particular about a proper soil as the Strawberry. Certain varieties seem to thrive almost anywhere, while others are profitable only on light, heavy, or medium soils respectively. It is thus extremely difficult to give the proper advice to beginners as to the sorts they ought to grow. A good general rule would be this—Make yourself acquainted with the varieties that have already proved suitable to your district; depend mainly on these for a few years; meanwhile test a few dozens each of other likely varieties, retaining for extensive planting those that prove the most suitable. A very good selection of promising varieties may be made from any grower's descriptive list if the main characteristics of roots, foliage, and flower stems, as noticed in a former paper, be borne in mind, and also the nature of the soil in which they are to grow. At least four years of trial will be required before we can decide on the most desirable; for not only do we wish to know what will bear the best crops the first or second year, but for a succession of years. Some exhaust themselves in one or two seasons, while others continue to bear heavy crops for five years or more; and in fruit-farming on a large scale such long-enduring varieties are most required.

But while, as I believe, there exist varieties of Strawberries to suit almost any soil, from mere sand or gravel to stiff clay, we must not lose sight of the possibility of making our soil to suit the variety. There are certain general requirements of the soil that cannot be dispensed with if we are to farm with profit. In the first place, it must be sufficiently rich to afford the necessary nutriment to the plants. If not so naturally, it must be made so by liberal dressings of manure well dug or ploughed in. A crop or two of Potatoes well manured is in such cases an excellent preparation. This not only enriches the soil, but ensures that the surface is thoroughly pulverised, aerated, and cleared of weeds. Light soils require heavy manure, such as cow's or pig's, while heavy soils require the lighter manure of the stable. With such a preparation it is not necessary to manure so heavily when the Strawberry plants are to be set, and thus the often excessive growth of runners the first year is prevented. The young roots are encouraged to go further in search of nourishment, and the plants become therefore more robust. A moderate amount of manure applied thereafter year by year as a mulch is much better than a heavy dressing at first and subsequent neglect.

In the second place, the soil must be of a nature to retain moisture for a long time, for the Strawberry loves moisture. It is a mistake to think that a naturally wet soil meets this requirement. I have seen clay lands baked like bricks during a spell of dry weather, while our gravelly soil still retained sufficient moisture. The proper thing is a soil rendered friable by deep cultivation, thoroughly drained if naturally stiff and retentive, and well mulched and mixed with well-decayed manure if of a light dry nature. Such a soil will longest retain moistness, and at the same time speedily dispose of any excess. Our experience in this quarter would seem to prove that a porous subsoil, though only of rusty gravel, is almost of equal importance to a suitable upper stratum. Probably it acts beneficially by allowing the free escape to the surface of the underlying water in the form of vapours. A subsoil of clean sand seems, on the other hand, to have the power of passing moisture downwards but not upwards, which may account for the total failure of Strawberries which I have observed in such a district. Where soils of opposite extremes are immediately contiguous, or, as is sometimes the case, actually superincumbent on one another, much good may result from judiciously mixing the one with the other. Thus by mixing, trenching, subsoiling, draining, manuring, and preparatory crops, or by such only of these as meet the case, we need not despair of preparing a proper soil for this somewhat capricious crop. Success is certain if it be intelligently done, and the expense is really insignificant when compared with the difference between a good crop of, say, three tons per acre, and a poor one of one ton.—WILLIAM RAITT.

THE FORESTS OF AMERICA.—Mr. T. Meehan states that "in the States of Virginia, Tennessee, and North Carolina there are, at the present time, millions of acres of magnificent forest trees. Among these are White Oak, Chestnut Oak, Red Oak, and the Tulip Poplar in immense quantities; with a great quantity of species, useful but less known, used in the leading arts, such as Beech, Birch, Elm, Sweet Gum, Black or Sour Gum, Buttonwood, Linden, Cucumber, and other Magnolias, Ash, Sugar, and other Maples, Locust Chestnut, and Horse Chestnut, Walnut and Hickory, enormous

Sugar Berry Trees, and Dogwoods larger than in the north, besides many others interesting to the botanist, but for which the special uses have yet to be found. Besides these, there are among the resinous trees immense quantities of the yellow Pine (*Pinus taeda*), Bull Pine (*Pinus mitis*), and Post or Jersey Pine (*Pinus inops*), which grows up into forests of straight trees, very different from what we find them in New Jersey and Pennsylvania. Besides these are Hemlock Spruce in some quantity, White Pine in less, and in still smaller quantities Balsam Fir (*Abies Fraseri*) and Black Spruce (*Abies nigra*)."

### COTTAGE GARDENING.

(Continued from page 30.)

A THATCHED-ROOFED cottage with a porch embowered in Jasmine; Roses and Honeysuckle covering its front walls; on one end a Bon Chrétien Pear tree, on the other a Morello Cherry, and on the back a couple of Green Gage Plums. A path leading from the wicket to the porch with a flower border on each side of the path, and behind each border a row of espalier-trained Apple trees, four on each side, all of them so famous for the abundance, size, and quality of their fruit that the names must be given. Keswick Codlin was held in high repute because it hardly ever failed to produce a plentiful supply of its soft yellow fruit, so excellent in tarts and puddings. Duchess of Oldenburgh almost equally productive, and even more attractive with its gaily-striped fruit. Warner's King and Alfriston, both as famous as prize-winners as for the huge Apple dumplings for which the noble fruit was mostly used. Margil and Cox's Orange Pippin alike excellent and commanding a ready sale. Cox's Apple attracting most attention by its high colour; but Margil was quite certain to be equally sought after when it had once been tasted. Hanwell Souring, so much valued for its good keeping and the abundance of its fruit; and a Ribston Pippin, somewhat prone to canker, but rich-flavoured fruit were the pride and boast of the cottage, whose occupant, John Brown by name, always declared, "There's nothing like a Ribson for flavour or sweetness."

The flower borders were thus shut in from the vegetable ground by a fence at once ornamental and useful. The scene as viewed from the wicket formed a pretty picture framed by the espaliers, for the flower borders were always neat and trim and well filled with plants, almost all of them living in the open ground through winter; and the only culture required after they were first planted was division and fresh planting when they became too large or weakly in growth, for it is the habit of plants of this class to spread into large tufts, so that in time they crowd each other, the roots exhaust the soil, the growth becomes weak, and the flowers small. When the division and fresh planting is done some road scrapings mixed with the soil make the plants grow freely and strongly. The tall-growing plants were kept mostly at the back, with a few of the best of them standing singly near the front to show their full beauty and to make a break among the lower-growing plants. The path had a fringe of the pretty little pink-flowered Thrift, with a row of white Pinks behind it. Enough Thrift had been obtained for this by dividing some large old plants that had spread too far in the borders; and the Pinks were the side shoots of some old plants cut off about 4 inches long in July and inserted 2 inches deep in a trench made for them behind the Thrift, just as they were taken off the old plants without any trimming whatever, especial care, however, being taken to settle them firmly in the soil and to keep them well watered. They grew and made plenty of roots that summer, and in another season were fine plants. Of other fragrant plants there were Lavender, Rosemary, Southernwood, Sweet Briar, several Cabbage Roses, a pink Moss Rose, a white Damask Rose, and a couple of the familiar Chinese Monthly Rose. Among the most notable other flowers were Meadow Sweet, Columbine of various colours, Jacob's Ladder, purple and white Rocket, purple Honesty, Crown Imperials, Solomon's Seal, Pansies, Spiderwort, pink Loosestrife, Michaelmas Daisies, Wallflower, Sweet William, Foxglove, Willow Herb, Snapdragon, double Daisy, double Feverfew, Canterbury Bell, Japan Anemone, Everlasting Pea both white and red, a large blue Iris, some pretty clumps of London Pride, and striped Gardeners' Garter Grass mingled together, Lily of the Valley that had spread along near the Apple trees, some curious old varieties of Cowslips or Oxlips, a clump of Christmas Roses, and in a sunny corner by the porch quite a bed of blue Russian Violets, which came into bloom in autumn and continued to bear flowers throughout winter if the weather held mild. A few Crocuses, Snowdrops, and Tulips threw up flowers every spring, but beyond sowing a few pinches of Mignonette and Stock seed there was no addition made to the border flowers in summer. Sweet Peas were always sown near the bee hives twice, to secure plenty of early

and late flowers for the bees. Some scarlet Pimpernel always sprang up among the flowers and was cherished there, and known as the "Poor Man's Weather Glass," because its flowers invariably close before rain.

Not often is it that one sees so many good old flowers brought together in a cottage garden, too many cottagers resting contented with a few miserable straggling plants, the hardy nature of which enables them to continue living and flowering amid the neglect surrounding them. Like many other things closely bound up with a man's home life, a garden affords an indication of character; and the sight of such an one as that which I have described enables one to predict very confidently that its owner has praiseworthy self-respect and is a good husband and father, loving his home so well as to exert himself to render its surroundings bright and cheerful. Occasionally we meet with very successful attempts at higher things. The culture of a few familiar old favourites has awakened a longing for better things, a sense of what is beautiful grows keener, and flowers of more refined aspect and more difficult culture are taken in hand, often to be brought to a greater degree of excellence than is achieved by professional gardeners. Of such I have seen Roses, Hollyhocks, Carnations, Auriculas, Asters, and Zinnias extremely well managed, and not long ago I was asked to look at a fernery that had been tastefully made under the shade of some trees at the bottom of a trim little garden. The space devoted to flowers must of necessity be very limited; and while fully admiring the Ferns, I must confess that the space given them might be turned to better account for a bed of late Strawberries. What! Strawberries in a cottage garden! Yes, why not? I have never seen a good bed of Strawberries in a cottage garden, and have always been puzzled to know why.—EDWARD LUCKHURST.

(To be continued.)

### HARDY FRUIT GARDEN.

THE recently experienced sharp weather will by retarding growth prove advantageous to fruit trees, the buds of which were generally too advanced for the time of year. Advantage should be taken of such weather to wheel in the requisite quantity of rich thoroughly decomposed material for top-dressing the borders containing espalier, bush, and pyramid fruit trees, which are too often neglected in this respect. The thoroughly decomposed material furnished by the rubbish heap is very suitable, choosing favourable weather for pointing it in; but when the roots are near the surface the soil should be scraped away down to the roots, supplying the enriching material, and lightly covering with fresh soil. Charred refuse is also an admirable dressing for fruit borders. Where planting young fruit trees has been deferred the necessary preparations for their reception should be delayed as little as possible. The ground must be thoroughly drained, otherwise it is hopeless to expect fruit trees to continue in a healthy fruitful state. Most hardy fruit trees may be successfully planted during next month, or even later, providing care is taken to expose the roots to the air as short a time as possible. It is always advisable before planting young fruit trees to trench the ground two or more spits deep, being guided in this respect by the character of the soil. Where pruning bush fruits has been deferred on account of bullfinches it is advisable to commence when the buds are swelling freely, or the pruning will enfeeble the growths of the parts retained. The object of pruning is to afford to every branch free exposure to light and air, and to improve or preserve the symmetry of the bushes. Retain the shoots or branches of Gooseberries about 9 to 12 inches apart, and regularly disposed around the centre, cutting back all others to two or three buds, and any strong shoots not required should be removed. Red and White Currants require similar treatment, but Black Currants should only have such growths cut away as are too crowded, shortening those that have extended beyond the limits assigned them. After pruning apply a dressing of manure, and point it in when the weather is favourable. Cuttings of bush fruits may now be inserted, choosing strong straight growths, cutting to a foot in length, and removing all the eyes except three at the upper

part. Raspberries may be pruned, thinning out the canes to from four to six to each stool, securing them to stakes or a trellis, and shortening them to  $4\frac{1}{2}$  or 5 feet. The old canes as well as those of last year's growth not required should be cut off close to the ground.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—In the house started in November the trees will now be flowering, and will need daily attention in fertilising the blossoms. As soon as the fruit is set syringing both morning and early afternoon will be required on all favourable days, the water employed being of the same temperature as the house. The temperature may be maintained at  $55^{\circ}$  at night and  $60^{\circ}$  in the day, with a rise of  $10^{\circ}$  to  $15^{\circ}$  from sun heat. Disbudding must be attended to carefully at this early season, so as not to give a check to the roots. If aphides appear fumigate moderately when the foliage is dry. In the house started this month the buds are swelling fast. Keep the night temperature at  $50^{\circ}$ , falling to  $45^{\circ}$  by morning in severe weather, allowing an advance to  $60^{\circ}$  or  $65^{\circ}$  from sun heat. Syringe the trees morning and early afternoon, so as to allow them to become dry before night. As the blossoms expand discontinue the syringing of the trees, but keep the pathways, borders, and other available surfaces damp, taking advantage of bright sunny days to ventilate freely, leaving the ventilators slightly open all night as well as by day in dull weather. Where there are several houses, and a continuous supply of fruit is required, preparation should be made for starting another house early next month, carefully dressing the trees, securing them to the trellis, and before starting give a thorough soaking of water at the roots at  $75^{\circ}$  to  $80^{\circ}$ . The house may now be closed, but no fire heat applied except to exclude frost. Outside borders should be protected with leaves and litter.

*Cherry House.*—More danger of failure arises from the impatience of heat during the early stages of growth of the Cherry than most other stone fruits grown under glass; this in combination with imperfect ventilation is a frequent cause of disaster. Maintain  $50^{\circ}$  as the point at which to open and close the house, and above that degree maintain a current of fresh air through the house. By day, from fire heat,  $55^{\circ}$  is sufficient, and  $40^{\circ}$  at night, falling a little during the night, but not lower than  $36^{\circ}$ . Syringe the trees on fine mornings; and now the buds are bursting it will be necessary to keep a sharp look-out for aphides, fumigating when necessary. Moisten the surface of the borders whenever they become dry, and cover the surface with about 3 inches thickness of partially decomposed manure as a means of encouraging surface root-action. Trees in pots will need to be examined occasionally, and liberally watered when necessary.

*Melons.*—Little requires to be done in this department at present. The earliest plants are growing well, and if the seed was sown singly and low down in the pots a little warmed soil must be added as the plants advance; or if sown several round the sides, the young plants must be carefully potted-off singly in previously warmed compost, watering sparingly for the present, and keeping them near the glass in a temperature of  $70^{\circ}$  to  $75^{\circ}$ , falling to  $65^{\circ}$  on cold nights; bottom heat  $80^{\circ}$ . Plants intended to be grown on a trellis need not be stopped, but should have the laterals pinched out until the plant reaches the trellis, securing the stem to a stick. Plants intended for pits or frames should be stopped above the second rough leaf. Let the necessary soil—mellow turfy heavy loam, with which is incorporated about a fifth part of old thoroughly decomposed cow manure—be placed in a dry shed at once, chopping it in pieces the size of a hen's egg. Fermenting materials must also receive a due preparation in mixing, turning, &c., if possible protecting them from heavy rains.

*Figs.*—Trees started early in December are in active growth. Maintain the night temperature at  $55^{\circ}$  to  $60^{\circ}$ , and  $60^{\circ}$  to  $65^{\circ}$  in the daytime, commencing to ventilate at that temperature, allowing an advance from sun heat to  $75^{\circ}$ , ventilating between  $70^{\circ}$  and  $75^{\circ}$  freely. In dull weather raise the temperature in the house occasionally to afford ventilation, if only for an hour or two, which will prove beneficial. Keep the bottom heat steady at  $75^{\circ}$ . When the shoots have made a growth of 4 or 5 inches stop them, pinching out the points of each, and remove all superfluous ones, retaining no more than have full exposure to light and air. Copious supplies of weak liquid manure will now be necessary, seeing, however, that the drainage is in good

order. Mulch the surface of the pots, if not already done, with about 2 inches of decomposed manure in a lumpy state.

*Cucumbers.*—As days lengthen heat and moisture may be slightly increased, but it is well to be careful in this respect, as there may yet be much cold weather. Do not syringe the foliage except on bright warm afternoons, when it may be done lightly and early. Damp paths, walls, &c., in the morning and early in the afternoon. Examine the plants not less frequently than once, better twice a week, removing unnecessary shoots. Young plants must be kept near the glass to secure sturdy growth, and nip the point out of such as are required for pits or frames immediately above the second rough leaf. Prepare fermenting materials, so that there may be no avoidable delay when the time for planting arrives. Mellow turfy loam, ridged up about twelve months before using, suits Cucumbers. Have it under cover at once, chopping up as advised for Melons, and adding about a sixth of thoroughly decomposed cow dung.

#### PLANT HOUSES.

*Greenhouse.*—Camellias should be examined at least once a year, and be thoroughly cleaned, which applies equally to those planted out as to those in pots. Where plants in borders have become thick or thin and straggling cut a portion of them in, and after making a season's growth they may be taken up and potted or placed in boxes, their removal allowing more room for the development of those retained, and the plants removed will make good specimens. If there is any appearance of the bed becoming exhausted remove a little of the soil from the surface without injuring the roots, and supply fresh soil. If any plants in pots are suffering from want of root space they should be repotted before the shoots begin to grow, for if deferred until the growth is advanced the season's growth will be injured. In potting make the new soil as firm as the old ball. Light turfy loam is a suitable compost.

Azaleas have now almost shed all the leaves they usually throw off during winter, and their appearance will be much improved by hand-picking, removing all that are yellow. Thoroughly ripened healthy plants are producing young growths from the base of the flower buds, which will not in any way interfere with the flowering, as is generally supposed, for that depends on the well ripening of the buds in autumn. The young growths will cause greater activity at the roots, the plants necessarily needing a little more water. Plants required for late bloom should be in a house with a north aspect. Young plants desired to be grown-on quickly may be placed in heat, to give them as long a season's growth as possible. They will then make considerably more progress than allowing them to start later on.

A few Fuchsias should now be started for early flowering. Cut back plants of a year or two's growth, and repot them in good loam with about a fifth of thoroughly decayed manure. They should have the balls reduced at least one-half. Place in the temperature advised above for *Daphne indica*, and sprinkle overhead occasionally. If a few plants of *Lilium longiflorum* and *L. auratum* are encouraged with a little extra warmth they will flower early and be very useful for decoration. Lilies that have been placed in dark situations must not remain until they have new growth, or they will in a very short time be seriously injured. Remove them at once to a light position, keeping them moist. Supply *Cinerarias*, *Primulas*, and *Cyclamens* advancing for bloom with weak liquid manure, and keep the plants near the glass. Watch for aphides, and fumigate on their first appearance.

#### SUCCESSFUL BEE-KEEPING.

##### THE CHALLENGE—PAST AND PRESENT.

THOUGH I do not quite understand what Mr. Mann means in his challenge published on page 520, December 2nd, 1880, I am glad he has made one for a contest of some kind, inasmuch as it shows that he has the courage to defend his opinions. If he will kindly explain his proposal and leave it open for consideration and acceptance I shall be obliged. It will be remembered by

some of your readers that it was reported the first Crystal Palace show of bees and honey had doomed the poor straw hive to extinction. About the same time the Stewarton hive was strongly recommended and ably advocated. If I remember rightly we were told that both the shape and materials of this hive helped to make the yield of it 200 or 300 per cent. more than other hives. Mr. Lowe of Edinburgh and myself thought differently. The virtues of the Ligurian bees were exceedingly lauded too. I thought then, and still think, that a fair trial of strength, or a Derby day in the apiarian world, would be of advantage to bee-keepers both old and young all over the country. Well, I offered to set down five straw hives of common bees within one hundred miles of Manchester against five hives of any other kind filled with any kind of bees—common, Ligurian, or half-bred. This challenge remained open for acceptance four or five years, and last time it was repeated the readers of this Journal were told that if not accepted in six months it would be withdrawn never to be repeated, owing to my advanced age and feeble health. No one accepted this challenge. Now Mr. Mann offers to meet me. The same reason that made me withdraw my offer prevents me from entertaining the idea of accepting Mr. Mann's proposal whatever it is, and will prevent me from engaging personally in exciting contests. But there may be younger men who may be willing to meet our Perthshire friend on a fair field, and I now ask him to inform us on what conditions would he like a contest to take place?

The question for decision, as I understand it, is, Which hive is best for honey and profit? not Which bee-master is the best man? nor Which locality is best for bees? When Mr. Rennie saw Mr. Mann's challenge he said, "It is easy for Ayrshire and Perthshire bee-keepers to compete with Carlisle folk. You are aware we have a cold clay soil, the worst for Clover I have ever seen. I would be willing to try any of them on the same pasturage." Mr. Rennie, who lived some years in Perthshire and Aberdeenshire, and kept bees there, once told me that the land there is much richer and warmer than it is about Carlisle, and that the Clover there yields honey in greater quantities. The gatherings of his bees on the Clover in Perth and Aberdeenshire astonished him. No satisfactory or deciding contest can take place between hives standing far apart or in different localities. Last summer I had nine hives at Stretford and nine at Chorlton, two villages in Lancashire about a mile apart. At Chorlton the bees did much better than those at Stretford. Rich warm soils are more productive of honey than poor ones, not only where Clover grows, but where Heather and other plants grow. The Carlisle bee-keepers have Heather in their own parish on heavy wet land, about three or four miles from the village; but for the last twenty years many of the hives have been taken to the Carnwath and Tinto Moors, fifteen and twenty miles distant, on which bees gather honey faster. These facts are now mentioned in order to convince all persons that a fair trial of strength can take place only between hives standing beside each other. Believing that Mr. Mann and Mr. Rennie are both very clever and far advanced in the art and practice of successful and profitable bee-keeping, I should be much pleased if an arrangement could be made between them for a contest, which in a good season and well reported would demonstrate what skill in bee-keeping can do for working men, and what bees might be worth to the community. Last year some working men in Scotland made from £50 to £80 each from their bees by attention to them after their regular hours of work. I have been gently reproached for giving encouragements to a class higher than working men to keep bees, but this cannot be avoided. Scotchmen need no more stimulus in this direction, and they needed not the stimulus of last year's great success. When will the working men of England resemble those of Scotland in the matter of bee-keeping? Stimulus and example here are necessary, and will be necessary for years to come; and how small is the desire for information on the subject! Exhibitions are doing something to awaken and keep alive a desire for knowledge of bee-keeping in some places. Reported instances of success do more, and I believe that well-conducted competitions would do more still. In competitions honestly and fairly conducted there is nothing to fear, for those who lose the day gain something better than victory—viz., knowledge by experience; they find out that they are wrong. We cannot learn much, if anything, from those who think as we think.

The difficulties of arranging and carrying out a trial of strength between hives of bees is great, and if the owners of the hives live some distance apart the necessary expense of a trial would be considerable. Working men have no money to spend in pursuit of the mere honours of victory. We live in the hope that the value of bees to the community will be better understood; that our associations for the advancement of apiculture will obtain

greater and more general support, so that larger prizes will be offered at public competitions and exhibitions; and that handsome rewards will be offered for great results in bee-keeping.

May I be allowed to suggest that an attempt be now made to raise by subscription a sum of £30 or £40 to be offered as a premier prize for the best results in 1881 from a hive of any kind managed on any principle? If any respectable committee or existing association will undertake to carry out this idea I will commence the subscription by promising £2. If two premier prizes of £40 each could be raised, one for English and the other for Scottish bee-keepers, a very great step would be taken to advance apiculture in Great Britain.—A. PETTIGREW.

#### THE MANAGEMENT OF HIVE ENTRANCES DURING SNOW.

THE almost arctic weather with which we have been so very suddenly visited, just as many were discoursing upon the fulfilment of the predictions of a mild winter, render opportune the illustration and explanation of a little device which I have proved to be as effective as it is simple. Every bee-keeper who has the experience of a winter or two knows that a sudden outburst of sunshine when snow covers the ground is likely to occasion much loss to his bees and distress to himself unless some precautions have been taken to prevent it. It is the nature of bees to revel in the beams of the king of day, whose advent is to them always welcome, as their call to the pleasures of honest labour. We can understand then how after an enforced confinement because of cold and gloom without, extending perhaps to many days, his bright beams peeping in at the hive door occasion so much excitement that prudence is forgotten, and that the impatient throng, lured abroad by the chilly splendour, soon dot the snow, from which the greater number never rise.

I can imagine nothing more distressing to a real lover of his bees than to stand before his stocks and find that thus the misjudging insects are falling around him in thousands. Many years ago this was once my experience. To stop the hive doors at the moment seemed a remedy worse than the disease, as this would prevent the ingress of those on the wing, and I then could only hope that the sunshine, of which before I never had too much, would soon be cut off by some bank of cloud.

Two precautions have hitherto been recommended to prevent this evil. First, to close the hive door; second, to shade the front of the hive. From the first of these I entirely dissent, believing that bees never need to be, and never should be, confined to their hives except when on a journey. Quietude is one great essential of successful wintering and bees no sooner discover that they are prisoners than a most exhausting and distressed excitement takes possession of them. If bees with open door be placed in perfect darkness in a room they will not leave their hive, and rest will reign within; but if the hive door be closed uproar is the result, and muscle and nerve, honey and pollen, are all together going to rapid destruction at once. An instance came under my notice of a bee-keeper attempting to winter some imprisoned stocks in a dark cellar. The buzz caused him to desist very early in the spring, and every bee died soon after removal to its outdoor stand. The reason is apparent—useless battering against the prison walls had beaten the life energy out of the stocks, and the chill of an English spring gained an easy victory, simply having to complete the work of exhaustion, which the misjudged care of the bee-keeper (?) had commenced. If bees are so kept to their cluster by cold that they cannot attempt to leave, and so do not learn their imprisonment, the confinement is clearly useless; but if they may attempt to make an excursion abroad it is as clearly mischievous—so mischievous, indeed, as to be not infrequently the proximate, and sometimes the immediate, cause of death to the entire colony. That it may be the proximate cause I have already pointed out, while if dead bees gather in the stock they will be brought to the "perforated zinc" door, and as they accumulate the stoppage of all ingress of the essential oxygen will enable the cold to do its work.

The second recommendation—the shading of the hive door, is effective, but it demands time and attention, and has the disadvantage of somewhat altering the appearance of the hive front, and so unhappily hindering the return of the bees that have ventured upon a cleansing flight. To save time and conquer the little disadvantages named I have introduced a modification into my "anti-robbing porch," of which I wrote in the issue of October 11th last, and the entrance as it now stands I find so extremely useful that I would urge the adoption of it with all earnestness consistent with modesty.

The value of this entrance in preventing robbing need not again

be fully stated, while it will be seen by comparing the illustrations now given with the article referred to. The slip (A B C, fig. 16) is cut about 2 inches wide, and quite twice the length of the hive opening. The thin blocks (D and E) are of wood, about three-eighths of an inch thick, while they are made from a single piece by saw cuts, giving to one part a point and the other an indentation. The piece D is fixed to A B C, while E is free to slip backwards and forwards. These are now turned down upon the

Fig. 16.

alighting board, when they are seen as in fig. 18. In summer the parts will stand in the relation shown in fig. 16, when the point and indentation present no impediment to the passage of the busy throng from *f* to *g*; but for weak stocks, or when robbing may be apprehended or is observed, or after swarming if the weather be cool, it will be desirable to narrow the entrance, causing E to approach D, more or less giving to it the position in

Fig. 17.

fig. 17. The bend in the tunnel (*f'*, *g'*) will assist in protecting from cold pulsating winds, and also add to the difficulties of an attacking party in the case of robbing, while in winter it not a little saves from draughts as aforesaid, but absolutely overcomes the difficulty which has engaged our chief attention by totally preventing the possibility of sunshine entering the hive. A small stud placed under A B C, opposite the point of D, fig. 16, will prevent the danger of the pieces being pushed so near to each other

Fig. 18.

that the mouth may be practically closed. He would be but a poor carpenter who could not for himself make this form of entrance, which costs but little both in time and material, and seems to cover all ordinary emergencies.—F. CHESHIRE, *Avenue House, Acton, W.*

\*\* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Pelargonium "Guillon Mangilli" (A. S. D.).**—You will find this variety, which has been so much inquired for of late on account of its value for winter blooming, advertised in the present issue of the Journal.

**"Rosarians' Year Book" (R. J. C.).**—It can be obtained either through a bookseller or direct from the publishers, Messrs. Bennrose, 23, Old Bailey, London, or at Derby.

**Insect on Vines (W. Martin).**—The specimens sent are pupæ of some two-winged fly, species uncertain till some are reared. Kindly state under what circumstances they were discovered.

**The Pomegranate (J. S. U.).**—This plant, which is the *Punica Granatum*

of botanists, is a member of the natural order Myrtaceæ. It is grown outside in the southern counties of England, generally trained to a wall with a sunny aspect, where it flowers; but we do not know an instance of fruit being matured. A moderately light garden soil suits it, and it needs little attention, except in training or thinning the shoots. You will find an engraving and description of the plant in No. 759 of this Journal, which may be obtained from the publisher, post free 3½d.

**Potatoes and Apples Frozen (F. J.).**—According to your description of the tubers they will be all spoiled if they remain where they are however thickly you may cover them now. See our reply to another correspondent. Apples will endure much more frost than Potatoes; and probably if you cover them thickly and let them remain covered until the frost is gone, a portion of the fruit at least will remain sound. Some varieties of Apples are more hardy than others, but all of them will resist several degrees of frost. If you bury the Potatoes you must do so at once. If you remove them to a warm temperature the sudden change will inevitably cause their destruction.

**Glazing without Top Putty (F. C.).**—The information required is at page 550 of our last volume—viz., "In forming the rebate in the rafters and sashbars half an inch is deep enough, and a quarter of an inch wide for the reception of the glass," the glass to be bedded in putty in the usual way, and secured with copper tacks. "No upper putty should be used, but have the putty (not wood, as stated at page 550) dressed off level with the glass." The rebate is formed in the usual way, and does not differ from that of sashbars for windows or glass structures, and is different from a groove, which is unnecessary and unsuitable. The method of glazing is simply the old-fashioned one without putty over the glass. It is important that the glass be firmly embedded in the putty; the roof will then be perfectly watertight.

**Potting Trees for Orchard House (Idem).**—The trees now in the open ground should be taken up as soon as the weather is favourable, and have the strong roots cut back to admit of their being placed in the pots, but the fibres should be carefully retained. The pots should be well drained, and some of the rough of the compost placed over it to keep it free. Turfy loam rather strong is the best material for potting, working it well amongst the roots and making it firm. The Apricots should also be potted with as little delay as possible, and should have the strong roots shortened back, but the fibres carefully preserved. They should be potted firmly, adding about a tenth of old mortar rubbish to turfy loam. The potting of them will not prevent their fruiting this season, but being maidens last year it is doubtful if they have fruit buds. They will need some slight pruning. The Apple sent is not King of the Pippins, and we are unable to determine the name from the specimen.

**Frozen Potatoes (K. D., Bradford).**—We know of no plan equal to burying them in the ground. Dig a trench, spread the Potatoes as thinly as possible, and cover them with the soil, which should be mixed with the tubers; if this does not remove the frost and leave the tubers sound, nothing will that we are acquainted with. Potatoes that are left in the ground all the winter are usually sound in the spring, though, on account of their nearness to the surface, it is almost or quite certain they had been frozen. We have often observed a Potato that has been partly embedded in the soil frozen above where exposed, and sound below where embedded, yet the frost must have penetrated the soil below the Potato.

**Figs not Swelling (S. G.).**—Probably if you rely on smaller fruits in the autumn for producing the first crop in spring that the fruit will swell and ripen freely. If it does not, the failure will result either from imperfect fertilisation or some check received by the roots, or by sudden fluctuations in the temperature of the house. The flowers expand when the so-called fruit has attained to about a third of its size. If you refer to our issue of January 31st, 1878, you will find the Fig blossom illustrated, and much interesting matter relative to it. If you do not possess the number it can be had from the publisher in return for 3½d. in stamps, and a request that he send you No. 379 of this Journal.

**Potatoes for Exhibition (A. Clark).**—*White Rounds*—Porter's Excelsior, Model, and Schoolmaster. *White Kidneys*—International Kidney, Covent Garden Perfection, and Veitch's Improved Ashleaf. *Coloured Rounds*—Red Emperor, Radstock Kidney, and Blanchard. *Coloured Kidneys*—Garibaldi, Late American Rose, and Feu's Bountiful. As no one can rely on staging eight dishes of the best character from the same number of varieties we have named twelve sorts from which, under good cultivation, you may hope to select the number of dishes you require. Of Beets, Carter's Perfection, Suttons' Improved Dark Red, and Nutting's Selected are all good for exhibition.

**Heating with a Paraffin Stove (A. J.).**—The small stoves are useful, but too much is often expected from them. A horse cannot do so much work as a steam engine, nor a boy so much as a man. If the horse or boy are taxed beyond their strength they succumb, and the work is not done at all. It is the same with stoves. If overworked—that is, overheated, they, instead of preserving the plants, injure them. There is no remedy for your Cinerarias and other plants that are shrivelled; but some of the injury at least might have been averted if you had been satisfied with preventing the temperature falling below freezing instead of raising it to 40°. When stoves are highly heated for any length of time they must be injurious to plants. These stoves, when sufficiently large or numerous, will preserve certain plants from frost, but there is a limit to their effectiveness. The weather has been exceptionally cold of late, and your stove has been unequal to the work you expected it to do. We know of many other failures of a similar nature. When one stove is only adequate during an ordinary winter, two are requisite when the weather is unusually severe.

**Potting Vines (Subscriber).**—The best time for potting such Vines as require it is when they are commencing fresh growth in the spring, and before the shoots are liable to be broken during the operation. All Vines that are in large pots do not need repotting; it is only when the pots are crowded with healthy roots that the practice is necessary. Under other conditions repotting might be injurious rather than beneficial. The work must be done, and especially the watering afterwards, with great care; it is work for skilled gardeners rather than for amateurs and learners of Vine culture in pots. If you have not had previous experience in the work in question we do not advise you to repot all the Vines, but remove such of the soil from the pots as you can without disturbing the roots, and add a fresh compost of loam and a sprinkling of bone meal, eventually top-dressing with manure. By noticing the effects you will then gain experience of practical value, and be able to teach others.

**Camellias not Expanding (Florist).**—We submitted the specimen you sent to a skilful cultivator of Camellias who has the charge of a very large and superior collection of plants, and the following are his remarks on the subject—"It is difficult to ascertain the cause of Camellia buds failing without knowing minutely the circumstances under which the plant is treated. The cause may be simple and brought about by the neglect of some small point in culture, or it may be a natural characteristic of the variety which the utmost care and

best cultivation cannot remedy. The thick round-budded varieties, such as the one sent, are far more liable to fail than those with sharper-pointed buds. Camellias such as Countess of Derby, Marguerite Guillon, and others that are similar in the bud often cast off the buds when they commence unfolding, even when the plants appear in the best possible health. Varieties that are at all subject to this, and receive even a slight check, not unfrequently cast their buds, when more reliable kinds would not be affected by any such cause. The slightest check through dryness at the root, a very dry atmosphere caused by sharp firing during frost, or when firing has to be resorted to too quickly, excites them, and in consequence causes a number of buds to fall. One of the surest causes of failure was suggested last week—viz., not thinning out the buds. Plants in the best possible health, if allowed to carry every bud they set, would soon be exhausted, and a greater percentage of the buds in all probability would fall sooner or later. The number of buds a plant is capable of opening entirely depends upon the condition of the roots and the luxuriance of the plant. While the buds are swelling Camellias require more support than at any other stage, and if this is judiciously given a great number of flowers would expand which could not otherwise do so. The health of Camellias cannot always be taken from the appearance of the foliage, which in many cases appears healthy even when the roots are unsatisfactory. When in this condition the growth made is very short and weak, and more buds are set than the same variety would produce if in a robust condition. The soil about the roots in a wet, sour, unhealthy state will cause the buds to fall or decay. Again, if the young growth by any excitement advances early according to the forwardness of the buds the flowers seldom expand. Marguerite Guillon is very subject to this, as is also Weltonensis, a thick-budded white variety, very similar in the bud to the one sent."

**Frozen Vegetables (W. J. M.).**—It is doubtful if the stems of the Celery to which you allude were really frozen, as the frost you record would not be sufficient to penetrate the soil unless the ridges were unusually narrow. The tops of the plants if not covered would be killed, and the decay would gradually spread downwards, and eventually spoil the crop. It is for this reason that Celery should always be protected by covering the rows with straw or litter; still if the plants were frozen in the soil, as they sometimes are, they would be quite safe to use either in the ordinary manner or in soups, provided the heads were thawed very gradually by placing them in cold water, and the Celery was afterwards firm, not soft. When frozen Celery is washed in warm water it is impaired in quality if not spoiled. We have grown many thousands of heads of the variety you name in a district where the winters are much more severe than your own, and with care in protecting have had produce of excellent quality until the end of April. Some of the red varieties are more hardy than the white, but none is, strictly speaking, "frost-proof" when grown in the usual manner in gardens. Many vegetables are better after having been frozen than before; Savoys and the different varieties of Kales for instance, also Brussels Sprouts. Even if these are so hard that they can only be cut with great difficulty they are perfectly safe if, after having been immersed in cold water for a time, they remain green and fresh, but if soft and pulpy they are not fit for use; consequently frozen vegetables should never be cut and placed on the fire at once, nor should they be washed in warm water. As you conceive the subject is of importance information cannot be published too soon, and at least a week would be lost by the insertion of your letter before any reply could be inserted; hence we adopt what you will agree is a more prompt and practical mode of dealing with the subject.

**Potatoes for Market (Henley).**—Early Potatoes, as a rule, are more profitable than late varieties, as the former can be generally placed in the market before the disease seriously attacks the crops; but as you tried both early and late sorts last year your own experience will be your best guide. The nature of the soil and local circumstances must be taken into account in determining a question of this nature. Early crops do not exhaust the land to nearly the same extent that late crops do that are growing for three months longer; and by growing earlier a second crop of some kind can be had by planting winter greens, or sowing Scarlet Runners between the rows, or planting Coleworts or Strawberries after the Potatoes are cleared. Strong plants of Strawberries planted in August in good soil would, by frequent hoeings and a dressing or two of soot or other fertiliser in showery weather, produce a good crop the season following; but the plants must be good to begin with, and be planted under favourable conditions. Myatt's Prolific is one of the best of the early kidney Potatoes. In some districts the Early Rose is profitable, where the soil is of a dry nature and the produce of good quality. The American Beauty of Hebron is likely to prove a good early market variety. The quantity required for planting an acre depends entirely on the size of the sets and the distance of planting. About 16 cwt. of fair-sized sets would probably suffice, but we have known a ton of larger sets employed. Small trashy seed is not the most profitable, while a medium-sized tuber in good condition will yield about as well as a large one. The condition of the tubers is of as much, or more, importance than their size. A moderately small tuber with a strong sturdy growth before planting is better than a larger set from which the first growth has been removed, or planted with a cluster of thin weak growths. The time of planting must be determined by the condition of the seed and the state of the soil and weather. The seed tubers of all varieties of the early kidney type should have short stubby growths when planted—that is, the eyes should have fairly started; there will then be no blanks in the rows. But if the growths are much advanced they might be injured in the rough handling that usually occurs when planting large quantities. If Ashleafs are planted in a dormant state several sets often fail to grow. The condition of the sets must therefore be first considered. Next the soil. In light and dry soils we have found planting 4 or 5 inches deep in February or early March the best; in strong heavy soils a month later has been advantageous. The sets then have made more growth above ground, and have been planted nearer the surface—sometimes only an inch, or even less, below—according to circumstances. Then the weather must be considered. Never plant when the ground is in a wet sticky state. Far better is it to wait for a week or a fortnight, as for early Potatoes the soil cannot be too dry and powdery when the sets are planted. A sprinkling of superphosphate of lime in the rows before the sets are covered, just making the ground white, or say a handful to every 4 yards, is beneficial in nearly all soils. These remarks, founded on many years of experience, may be of use to you.

**Inarching Vines (Reader).**—You had better inarch to the young cane, taking a slice off it from 6 inches to a foot long as most convenient, and almost, or quite, down to the pith, with a corresponding slice in the cane to be attached. You will effect a quicker and firmer union than by merely removing the bark to the extent of a few inches. The slicing must be very smooth, and the "fit" of the two portions accurate. Secure them together with soft matting tied as tightly as you could endure the same ligature round your finger for a month, and cover the inarched portion with moss, which should be syringed occasionally. When the buds commence swelling is a good time for the operation, and one bud of the Alicante above the union will be sufficient; you had better, however, leave two for fear of an accident, and when one growth is safe the other can be

stopped as required. Let the new cane have plenty of room to develop its foliage, and light to perfect it, by removing the growths from the parent rods as needed. When Vines are inarched, overcrowding of the new canes often follow, and the success that is hoped for is consequently not attained.

**Names of Plants (C. F.).**—Azalea amœna. (J. S.).—Berberis Darwinii. (F. T. A.).—1, Yucca aloifolia variegata; 2, Specimen too small, perhaps Y. quadricolor.

# COVENT GARDEN MARKET.—JANUARY 26.

LITTLE or no business doing, our market being still completely frozen ont.

## POULTRY AND PIGEON CHRONICLE.

### AGRICULTURAL IMPLEMENTS AND MACHINERY.

(Continued from page 57.)

WE will now refer to a new machine exhibited at the Carlisle meeting of the Royal Agricultural Society by Mr. Frederick Savage, King's Lynn, Norfolk, and styled a combined self-acting presser and drill, and worked in the trial field by another machine, which the Judges' report describes as a ten-horse-power agricultural engine, the driving wheels forming the winding drums, which is usual in these engines. The anchors are self-moving, and the whole weight rests on the retaining tines. The new implement to which we wish to refer was shown in connection with this tackle—namely, a four-ring self-acting presser and drill combined, to be used behind the plough. A swivel foot lowered on to the ground by a lever takes the weight of the presser in turning at the head lands. A small harrow is also attached and drawn behind the presser for covering in the seed. This is the first implement of the kind ever made, so doubtless many improvements on it will appear in time, and in certain hands on some soils will probably prove of considerable value. This concludes the short notice by the Judges of implements and machinery at the Carlisle meeting. Our reason for bringing this implement to the notice of the home farmer is because we see in the invention the means of attaining that which we have for a long time in practical farming desired to see—viz., the ability to perform by ploughing, pressing, and seeding the land simultaneously by one operation. It will be no doubt easily adapted both for steam power and horse or ox labour in the Wheat season, as well as the Oat or Bean and Pea seed time. For the first object it is very important, because after the early part of the month of November the land cannot often be ploughed and left unseeded without incurring the risk of serious

delay, for in our climate we usually get either night frosts or rain; in either case the land often cannot be seeded.

This matter we have often referred to under "Work on the Home Farm," by recommending that the ploughing should never be done at the late period, unless it can be seeded at the same time; but this involves special arrangements of the working power both of men and horses, so that as fast as the land is ploughed it should be drilled and finished off, so that at any time of the day if rain should set in the work may be safe against any succeeding weather. We have often heard it readily admitted by practical men that this plan of proceeding is desirable; but that upon some farms, unless a considerable number of men and horses are available, it cannot be carried out exactly to an hour without some disadvantage as regards economy of labour. From this circumstance we can see the advantage of a presser following the ploughs and drilling the seed, and covering in with the harrows at one operation, in order that upon change of weather at any period of the day the work shall be in a finished state so far as it has been done as not to suffer in any respect. There is another point from which an advantage is to be derived, because the drill tubes follow in the line of the presser grooves, depositing the seed with such regularity and depth that the seed will not only be well covered, but the young plants will find a firm bottom, so desirable for the successful growth of Wheat. The comparison with ordinary drilling is therefore in favour of the new machine in various ways, and we reckon that a saving of seed would occur, amounting to one-fifth, if seeded by the press drill.

Referring to the seeding of Oats after lea, or the seeding of Beans or Peas, the advantages of burying the seed at a good depth and with a regularity not attainable by the ordinary drill, owing to the saving of seed, which would be considerable, as well as the importance of all the work necessary being done simultaneously. There was also exhibited at the Carlisle meeting a machine for planting Potatoes in the balk or stretch, two rows at a time. This was brought out by Messrs. Murray & Co., Banff, and it was awarded a silver medal, and called a "Potato Planter," price £18 10s., which when tested by the Judges on the grass in the yard gave every satisfaction. The Potatoes were deposited at perfectly equal distances, and in a length of 56 yards there was only one miss in each row, which probably would not have happened had the machine been working in the field. The cups which take up the seed are each a link of an endless chain merely hooked into each other, and on the end of each cup is a tail, which, as the chain turns over the supporting wheels, rise up through the bottom of the succeeding cup, thus not only ensuring the seed leaving the cup at the right moment, but clearing out any dirt that may have accumulated there. This is an important improvement, and effectually remedies a hitherto existing fault. Motion is communicated to the cups by means of the well-known Ewart's detachable drive chain, and there is also an adjustment for properly balancing the machine when going up or down hill. The seed can also be dropped at three different distances apart by a very simple arrangement of change wheels. The machines are made either for double or single rows. We can see very plainly that this machine is of great consequence, either for large or small occupations, when the hand labour is scarce. There is also greater surety of a regular setting than when done by hand-dropping, for we have often seen the seed irregularly dropped by the planters, and often a line or part of one missed altogether for want of sufficient care between the persons in planting.

These machines are made for planting between the stretches, so that the manure may be either yard or box manure laid between or artificials sown broadcast, so that when the stretches are reversed the manure and sets are covered in at one operation. With respect to the single-row planter we have no doubt but this may be made to answer the purpose of planting after the plough as the work goes on, the application of manures being the work of hand labour. We understand at the trial of the machine whole sets were only used; it is, however, just a question whether cut sets would work so well in the cups. For the present we conclude our notice of implements, &c., but hope to return to the subject at another time.

#### WORK ON THE HOME FARM.

**Horse Labour.**—This will be resumed when the frost and snow have gone; and as soon as the land is sufficiently dry the fallows, which have been left exposed during the winter, may if quite clean be scarified and reduced to a fine tilth in readiness for the drilling of Barley. We have sometimes known it done in the month of January, and it is no bad rule to take the first season, as the produce at harvest is more likely to prove a malting sample than that obtained from late sowings. At any rate we prefer sowing Barley early rather than Oats. We may observe that Beans, Peas, and summer Tares may be sown or drilled at the earliest season, whether it happen in the end of January or first week in February, in preference to either Barley or

Oats; and we consider a fresh furrow better than a stale one for any pulse crop, but especially for Peas, and for this crop we like to plough and sow simultaneously. We must also call attention to the advantage of a mixed crop, such as Beans with Peas or Vetches in admixture, for practically all these are more or less speculative in their yield. The object, therefore, of mixing is to insure as near as possible a full yield from one of them, for we find it is very seldom that Beans and Peas or Vetches suffer similar injury from the effect of the season, whether it is very wet or very dry. There is one point, however, worth notice by the home farmer—that in a very dry season, although it may be and is generally favourable for the yield of Wheat, but the reverse for Lent corn and the pulse crops—the home farmer should be early in sowing his Barley and pulse crops, for this will be found correct management nine years out of ten, whether the season after seed time proves wet or dry.

In consequence of the stormy weather in the autumn very few fields under autumn tillage could be entirely cleaned and freed from couch in a satisfactory manner; and at the time of fallowing, when the land was intended to lie the winter months, we advised that all those fields which were not cleared of couch fit for deep ploughing should be only rafter-ploughed, and thus left for the winter. As the frosts lately have been severe this land must have been greatly benefited by them, so that as soon as the land can be worked, and yield to harrows and drags, clearing off the couch may commence immediately where it has been rafter-ploughed only. Any of those fields which have been deeply ploughed and left for the winter, although the land has been benefited by frost, yet still require much costly labour to clean out the couch as compared with the rafter-ploughed land where the grass was kept on the surface. When the yard or box manure is intended to be applied for early Potatoes or, in fact, second earlies, it will forward the work to have the dung in heap near to where it will be required for use. Still, we do not advise the use of dung for early Potatoes, owing to the time required for laying out and spreading. We prefer rather to apply the best guano as a hand-dressing strewn into the furrow with the Potato sets at the time of planting. This practice is so simple, and takes so little time when the guano is mixed with damp ashes to prevent its flying before the wind, that where Potatoes are planted on a large acreage the time saved in the application of the artificial manure as compared with that of dung often makes the difference between a good seed time and a lost one, for often whilst carting and spreading dung is being done the Potatoes might have been planted and the land dressed with guano. Besides which, our long experience enables us to say with confidence, irrespective of the time gained in planting, that the application of 5 cwt. per acre of the best Peruvian guano or its equivalent has generally proved equal to any amount of town, yard, box, or stable manure which may be applied for the crop. We state this in order to show the home farmer that it is not necessary, as the market gardeners say, to apply heavy dressings of costly manure and labour in order to obtain a successful growth of Potatoes.

**Hand Labour.**—The cattle man now on the farms where stock of all ages are wintered must be careful to feed and shelter the animals according to their age and the purposes for which they will be required. For instance, the calves intended for beef at the earliest period should be kept entirely under cover in twos or threes, and fed with a fair allowance of cotton cake—say 2 lbs. each per day—with sweet hay chaff, and from 15 lbs. to 20 lbs. of cut Swedes per day, the cake being in meal and mixed with the cut Swedes. It is sometimes preferred to give maize or barley meal at the same cost as decorticated cotton cake, and to this we offer no objection. The calves intended for dairy stock may have cut Swedes and hay mixed with sweet straw in chaff, and be kept in well-littered yards and sheds. The cattle rising two years old will now, if intended for early killing, be well fed with an allowance of 4 lbs. of linseed cake meal and 2 lbs. of bean or maize meal per day with good sweet straw *ad libitum*, and about 56 lbs. of cut Swedes with the meal strewn over. They will then, if well bred and healthy stock, whether heifers or steers, be ready for sale at from twenty-four to thirty months old if they have been for the duration of twenty weeks kept in separate boxes under cover. The heifers for the dairy rising two years old will now for the most part be in calf if the bull has run with them as we advised in August last, and should be fed in yards and sheds with about 40 lbs. of cut roots per day, with 2 lbs. of cotton cake, and ordinary hay or straw mixed in chaff. In this way they will be in good condition at calving time, without being in too high condition, as when overfed often induces the quarter-evil or parturient fever at calving time. Cattle in the boxes of any age, whether of cows, heifers, steers, or oxen, should be fed at the outside allowance of food for at least twenty weeks before sale, and they often pay well for holding on at liberal feeding until the end of June or early part of July, especially when a good lot of Mangold has been carefully preserved for their food. The food we recommend for these is the same as that given to the baby beef animals, except that in case the Mangolds do not hold out good Clover, Trifolium, or Saintfoin *ad libitum* should be given instead.

#### VARIETIES.

**THE PALACE CUP COLOURED DORKING HEN.**—Mr. J. Taylor's celebrated old Dorking hen (formerly Mr. Parlett's), the winner of

the cup at the late Crystal Palace and Dorking Shows, has, we understand, recently changed hands.

— COLOURED DORKINGS.—We hear that Mr. James Cranston of Thornhill, N.B., who has exhibited Silver-Grey Dorkings for the last two years at Birmingham and elsewhere with such remarkable success, has recently gone in for coloured Dorkings, and we observe his name in the prize list at Kendal.

— LIABILITY OF RAILWAY COMPANIES.—The case of Adams v. the Great Eastern Railway Company, decided the other day at Ipswich County Court, is of some importance to fanciers. The Judge following another case (*Ashenden v. the Brighton Railway Company*) held that the bye-law framed by the Companies, limiting their liability in the case of dogs to £2, was void as being unreasonable, and a verdict was given for the plaintiff for £50, the proved value of a dog sent by the defendant Company's line and suffocated during its journey. The same bye-law generally provides for poultry and Pigeons as well as dogs, and the decision is thus of interest to our readers.

— PURE-BRED POULTRY.—Apart from the greater pleasure which it affords, it pays better to keep and breed pure-bred fowls than to breed and feed a lot of mongrels, which latter many do for fear of the expense of buying a few pure-bred fowls to start with. In determining which breed of fowls to get, make up your mind at the start that no one breed can or does possess all the desirable qualities you are in search of. If you wish a breed for laying get Leghorns or Hamburgs; if you wish them for weight get Brahmas or Cochins; if you wish them for ornament get the Polish; but give up the idea of getting a grand combination of all these qualities in one breed. Make up your mind what you wish in the way of fowls, and then select such breeds as will answer those requirements best. Give them good comfortable quarters, supply them liberally with water and food, giving them requisite care and attention, and you will never have cause to regret your investment in pure-bred fowls. When your neighbours see what fine birds you have they will naturally want some of them for a sitting of eggs, and thus will a demand be created which will amply repay your first outlay of cash and subsequent trouble and expense. If you had bred nothing but mongrels there would have been little or no demand, and then merely at market prices. A good trio of pure-bred fowls, of almost any kind, can now be bought at fair figures from reliable breeders in most sections of the country.—(*Farmers' Magazine*.)

— THE "MECHI FUND."—We are glad to state that the appeal of the Committee of the above fund is being liberally responded to by the public, and that several subscriptions have been received in addition to those already published. These include the Duke of Devonshire, £100; Mr. M. T. Bass, M.P., £50; Mr. Pickering Phipps, £50; Messrs. Barnard, Bishop, & Barnard, £26 5s.; Sir Thomas D. Acland, Bart., M.P., £25; Mr. Alderman Fowler, M.P., £25; Mr. Frederick T. Mappin, £25; Messrs. Ransomes, Head, & Jefferies, £25; Messrs. Sutton & Sons, £25; Mr. John Corbett, M.P., £21; Captain Jay, £21; Mr. O. E. Coope, M.P., £20; Mr. W. De La Rue, £20; Mr. James Garrett, £20; a Friend, per Mr. James Garrett, £20; Mr. W. Goldsmith, £20; Mr. F. W. Grafton, M.P., £20; Mr. Robert Hanbury, £20; Earl Spencer, £20; Mr. John Walter, M.P., £20; Messrs. E. Cook & Co., £10 10s.; Mr. J. Corke, £10 10s.; Mr. James Spicer, £10 10s.; and several others of similar amounts. The Committee are making a systematic appeal in the interests of the fund, and already applications—signed by the Lord Mayor, the Marquis of Huntly, and Mr. Samuel Morley—have been addressed to Members of both Houses of the Legislature, provincial Mayors, members of the Common Council of London, city companies, bankers, brewers, agricultural engineers, seedsmen, and agricultural chemists. It was stated at the last meeting that Sir Henry W. Peek, Bart., M.P., Sir Sydney Waterlow, Bart., M.P., and Messrs. Hunter Rodwell, Q.C., M.P.; James Round, M.P.; and Clare Sewell Read had consented to join the Committee, and that the following banks would receive subscriptions on behalf of the fund—viz., Messrs. Coutts & Co., 59, Strand, W.C.; Messrs. Glyn, Mills, Currie, & Co., 17, Lombard Street, E.C.; Messrs. Hoare, 37, Fleet Street, E.C.; Messrs. Martin & Co., 68, Lombard Street, E.C.; Messrs. Robarts, Lubbock, & Co., 15, Lombard

Street, E.C.; the London and County Bank, 21, Lombard Street, E.C., and branches; the London and Westminster Bank, 1, St. James's Square, S.W.

— PEASANT PROPRIETORSHIPS.—In a discussion on the "Land Question in 1880," at the Institution of Surveyors on the 10th inst., Mr. C. G. Grey spoke as follows:—"The question of peasant proprietorship in Ireland has been much ventilated of late. To talk of the possibility of the 277,000 tenants holding under 15 acres (referred to by Mr. Watney), living on such an acreage was absurd, and the results would be suicidal. The very small farmers of Ireland could not live on their farms in bad years. He remembered the famine of 1847—the horrors that resulted, and the exertions which all the residents of any position made to alleviate that distress. People were accustomed to regard the famine of 1847 as the only misfortune of the kind which had happened to Ireland; but, looking back into its history, it would be found that there had been a succession of famines in 1816, in 1821, in 1823, in 1827, in 1831, and in 1832."

— VEGETABLE FARMING.—"There was," said Mr. Savill at the discussion above referred to, "some little danger in recommending tenants what to grow. Some five or six months ago Mr. Caird recommended farmers to grow vegetables, and the result had been disastrous to those who had grown Cabbages and other vegetables. Many a man of small capital, who had tried the experiment, had found that it cost him, speaking in round numbers, some £20 an acre to produce his crop of Cabbages, which was not worth when grown £5 an acre—in fact, not worth cutting! The receipts were less than the outlay for the labour incurred in taking to market. No doubt the case was peculiar to the immediate neighbourhood of the metropolis, for in country districts the Cabbages could of course have been utilised for feeding stock."

— SPURIOUS BUTTER.—The *Irish Farmers' Gazette* publishes the following:—"The manufacture of substitutes for and imitations of genuine butter, now carried on so extensively in many sections of the West, is really a national calamity, as well as a fraud upon innocent and unsuspecting consumers. There are seven factories in Chicago alone, each turning out from 2000 to 18,000 lbs. per day of suene or lard butter. Car-loads of this bogus butter are being shipped eastward daily. What must be the effect of such illegitimate transactions upon the sale of western dairy products at our seaboard markets? How unfortunate to American interests, in the great and increasing export trade in butter, that this promising industry should be crowded out by new-fangled articles, having the semblance of butter, but carrying deceit and fraud in their contents. Our eastern dairymen will find an increasing demand for their butter product if bearing upon its face the impress of purity, and if marketed in such form and package as to distinguish it from the vile adulterations now being manufactured in the West. National and State legislation should protect an industry, now yielding one billion pounds of butter annually, from the schemes of unprincipled tradesmen, who would ruin the dairy business of this great nation in order to profit by the manufacture of a miserable mass of bogus stuff, wholly unfit to eat. The American dairy is too large a factor in the prosperity of the nation to be allowed to fall into disrepute through the selfish and unprincipled manipulations of dealers in suene, soapstone, grease, and oleomargarine."

## POULTRY AND PIGEONS

### ARTIFICIAL HATCHING AND REARING.

SEVERAL correspondents have written to ask for advice upon this subject. As we stated in answer to one of them last week, we purpose shortly giving a series of articles upon incubators and their management; we shall afterwards give a detailed account of the various rearing appliances in use. In the meantime, as the needs of some of our readers appear to be pressing, we now give in a condensed form the results of our own experience in these matters. The rules to be observed are as follows:—

Firstly. Let the eggs set be as fresh as possible, certainly not older than a week.

Secondly. During the first ten days keep the atmosphere of the incubator as close and moist as possible, and aim at a temperature of 202°. Take out the egg-drawer night and morning, and turn the eggs; but do not keep the drawer out longer than is necessary for this purpose.

Thirdly. During the remainder of the period of incubation keep the drawer thoroughly ventilated and fairly moist, and aim at a temperature of 104°. The egg-drawer may now be left out for ten minutes once a day to air the eggs, and the eggs turned twice a day as before. If the room be very cold cover the eggs with flannel when being aired. Where one drawer only is used, and the eggs are put in from day to day, those added each day should be put into a small box made to fit inside the drawer of the incubator for twenty-four hours until thoroughly warm, and the temperature should be kept about 103° throughout.

Fourthly. Test the eggs at about the sixth day, and remove the unfertile ones. Test them again a week later, and remove any which may have been passed over before, or which have not duly progressed. If you notice any foul smell in the drawer search for any eggs with moisture exuding and remove them.

Fifthly. As a precaution against damage from carbonic acid gas generated by decomposed eggs keep a small box or saucer full of quicklime in the drawer; cover this with fine wire netting or muslin to prevent the chickens getting into it. If chickens are constantly hatching out, a small cage made of very fine wire netting to fit in part of the drawer may with advantage be used for putting the eggs due to hatch under, and thus preventing the newly hatched chicks from running over the other eggs.

Sixthly. If any eggs due to hatch do not chip, they may be opened at the large end, and the portion of the shell covering the air vesicle removed. If the chick be alive put a drop of warm water on the membrane surrounding it, and this will render the membrane transparent. If there be blood circulating through the veins in this membrane nothing further must be done for some hours; but if there be no blood visible the entire upper part of the shell may be removed, the membrane may be torn off, and the head of the chick released. The chick should be then replaced in the drawer and allowed to get rid of the lower portion of the shell itself. If any blood flows from the ruptured membrane the process of releasing the chick must be postponed. Chicks which chip the shell at the small end of the egg generally require some assistance.

Seventhly. Allow the chicks to remain in the drawer of the incubator until dry, and indeed they may with advantage be left there or put in some equally warm place for twenty-four hours after hatching. If during the first few days of its life a chick shows signs of weakness, a few hours in the incubator will generally work wonders in the way of restoring it. It must be borne in mind that we assume that the hatching drawer is thoroughly ventilated.

Eighthly. After the first twenty-four hours the chicks should be transferred to the artificial mother. If chicks are constantly being hatched two mothers are necessary—one for the very small ones, the other for those over a week old. The best mothers are those in which the outer air is freely admitted, and the chick merely derives its heat from the under surface of the hot tank against which it can put its back. This surface, whether of metal or flannel, should be rigid or nearly so, and be of such a temperature that a thermometer left in actual contact with it for some time will register from 75° to 85°. The height of this surface from the ground should be such that the chicks can easily put their backs against it. A mother which gets filled with a hot vitiated atmosphere is most injurious, as it renders the chicks liable to a chill. A mother with an under surface which the chicks can raise by pressure is also bad, because in the struggle to reach the heat the smaller chicks get trampled on. We prefer a mother with a sloping under surface, as in it the chicks of various sizes can each find a spot to suit their height, and crowding is avoided.

Ninthly. It follows from what we have last said, that any great variations of the atmospheric heat to which the chicks are exposed should be avoided. Do not put the chicks into a greenhouse or room with a very high temperature unless you are prepared to maintain this temperature until they are reared. Indeed, any coddling is most unwise, and it is better to accustom the chicks to the ordinary temperature at once.

Tenthly. Let the chicks have as much exercise as possible, and keep them on dry clay, sand, or ashes, not on a wooden or stone floor. A sod for them to scratch will afford them green food and exercise. Do not confine them indoors except when it is unavoidable.

Eleventhly. Just at first you must pay rather close attention to the youngsters to see that they do not remain out too long and

perish from cold. They will soon get accustomed to run in and out from the mother, and then will be so far independent; but until they do, you must drive them in when they cry through cold, and if necessary keep them shut in for an hour or so several times in the day.

Twelfthly. Feed regularly, and give a little animal food.

Lastly. Pay scrupulous attention to cleanliness. Rake over the clay, &c., with a fine-toothed rake every day, and renew such portions of it as are at all foul when necessary.

With close attention to these rules we know that even highly bred delicate breeds can be hatched and reared artificially with as great a measure of success as under hens. It is contended by some authorities that artificial incubation is only suited to strong hardy birds and not to finely-bred stock. We have come to the conclusion that while the hardier sorts will stand greater variations in temperature during hatching than the highly bred varieties, yet that with treatment such as we have described almost any egg that would hatch under a good sitting hen can be hatched in a good incubator.

### A PLEA FOR POULTRY-KEEPING.

NOTICING the remarks in the *Journal of Horticulture* on page 603 of your last volume alluding to the dislike some gardeners have to keep poultry, I may say there are others who would be glad if allowed the privilege of keeping fowls at their own cottages, but many employers do not allow it to be done on their estates in the country. I am of opinion that it is highly desirable that much more attention should be given to the keeping and rearing of poultry, not only by farmers who should have poultry yards and allow the birds liberty to roam about, but by cottiers in their more contracted spaces or outhouses. Even if the birds were partly wired in it would be a pleasing sight to see them more generally kept in every village, their eggs being so useful and nutritious, and a six or eight-months fowl cooked so splendid for the table.

SUCCESSFUL POULTRY-KEEPING.—A word of encouragement in your *Journal* at the present time might induce many people to begin poultry-keeping. The flocks of sheep have been much reduced in 1880 throughout the country, and now there is disease among cattle in some districts; add to this the prospect of Rabbits being diminished now that farmers are allowed to kill them on the land they occupy. So that every extra new-laid egg produced and every fowl brought to table may help in a small way to mitigate the evil of a scarcity of food; and thus if the flocks and the herds fail we may have, like the Chinese, the domestic fowl to fall back upon.

I will now record an instance of success attending poultry-keeping in 1880, the breed being the White Dorking. On January 1st, 1880, "L. D." was the owner of a cock, two hens, and ten pullets. During the year the number of eggs produced was 1984, a correct register having been kept; six hens were set on twelve eggs each, thus reducing the number to 1912; the value of these at 8s. per hundred would be £7 13s. The chickens produced and reared were forty-two; and eleven couple of these have been killed for table. They were fine young birds, their average weight per couple being 8 lbs. The rest are fine pullets. The market value of the twenty-one couple, at 6s. per couple, would be £6 6s.—total value, eggs and fowls, £13 19s. Against this is the cost of their food as follows:—

	£	s.	d.
Four bushels of Maize .....	1	0	0
One ditto of Barleymeal .....	0	3	6
One ditto of Oats .....	0	3	0
Ten bushels Wheat offal cuttings at 1s. 6d. per bushel .....	0	15	0
Refuse vegetables, &c., from dinner table at 1s. 6d. per week ..	3	18	0
Total for food .....	£5	19	6
Balance, entire profit .....	7	19	6
	£13	19	0

The fowls have the run of a park, and roost in two sheds opposite each other. The backs are formed of walls. The east and west sides are partly wired in, about 1 yard being covered in by slates. The fronts are boarded half way near the wall where their nests are, the rest being wire. Doors open east and west in the yard in front of a cottage where the manager resides. The truth of the above statement can be verified by the manager, also by the owner from whom I obtained the information. I hope many may see their way to make a beginning in so important, useful, and profitable undertaking as poultry keeping and rearing, and that it may become more a national pursuit to the benefit of all engaged in it.

A POULTRY VILLAGE.—I will now refer to an example of poultry-keeping on a large scale—in this case, show poultry. I was on a visit last autumn to the north of England, a few miles from Manchester, where I had the opportunity of going through what I may term a poultry village. The enclosure was two or three acres in extent. The poultry pens were arranged in streets, lanes, alleys, and

cross roads, containing remarkably fine specimens of prize fowls, many of them feathered down to their feet; most of them kept for show purposes. I understood from the attendant they were a source of great profit to the proprietor, buyers sometimes paying as much as £1 for a sitting of eggs for prize fancy sorts. There were many hundreds of different varieties and various ages in pens, and hundreds more not in pens were basking in the sun; it was a grand sight to see them come running when called to their midday meal. I understood they were fed three times a day—at eight, at twelve, and at five in the afternoon. Now what I would like to see or hear of is colonies of poultry, the profitable domestic fowl, not so much for show as for general use scattered through the length and breadth of the land. I believe if more attention were given to the keeping and rearing of poultry by farmers, cottagers, gardeners, and amateurs it would be a wise and beneficial undertaking, and good for the country at large. Our French neighbours are far ahead of the English in this respect, and I have no doubt wonder at our short-

sightedness in buying from them what we might raise ourselves. —T. WALKER, *Gardener*.

["L. D." has a valuable stock. 165 eggs per hen for the year is above the average. Can Mr. Walker give us the monthly returns?]

#### SMALL POULTRY YARDS.

THINKING that my former notes on this subject might create no more than a passing interest, I only made what might be termed a few summary remarks on Mr. Clatworthy's unique poultry yard at page 560 of your last volume; but as it now appears that more minute details would be of service, I gladly comply with the request of "C. J." (page 604), and send a ground plan of the yard in question. At the same time I may say that my previous figures as to area and extraordinary number of fowls kept therein were quite correct. "C. J." cannot imagine what use the small coop-like runs at the top of the yard are good for,

Fig. 19.

A, Entrance; B, Small coop runs; C, Roosting places; D, Runs; E, Doors; F, Walk; G, Grass. Scale, one-eighth of an inch to a foot.

but if he saw them he would soon perceive their value. We are having some of the same kind constructed now, and fifty of them would not be too many for us. It will be seen there are six small coop runs on the ground floor, and there are other six of the same size and shape above them forming the second storey, and making twelve. The whole of the yard all round is roofed over. The fronts of the roosting places are of boards, and the runs have boards in front next the ground and wire above this until it meets the bottom of the span roof. The highest part of the roof is from 5 feet to 6 feet from the ground. The fronts of the top coops take the form of doors, with a square hole in the centre of each covered with wire, and a shutter behind this to close when necessary.—M. M.

#### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 60.)

THE greater degree of facility with which points which have been a long time in existence are reproduced may be accounted for as follows:—They have through length of time become characteristic of the variety as distinct from the several strains of which the variety is made up, and as a general rule the various strains have become so mutually crossed and recrossed that the whole variety is, in fact, only one family. Every attempt to introduce fresh blood is thus counteracted as to its ill effects by the fact that the new blood is more or less remotely connected with the strain into which it is introduced.

Again, even if there be no actual relationship between the two

strains, each bird has become so prepotent as to the points which have been established for a number of years that there is a prepotency in both parents as to the same points, and they are thus much more likely to be reproduced than if one of the parents were loosely bred as to the points in question.

As an illustration of our statement that in-breeding is largely resorted to by fanciers generally, and is not necessarily injurious, we may cite the following lines from the letter of a breeder of Turbits published recently in the pages of a contemporary:—"I have at this moment upwards of fifty Pigeons that are all bred from two pairs of birds that I bought ten years ago. They have never been crossed; they are perfectly healthy; are, many of them, larger and better in their fancy points than the birds they were bred from, one of which is still alive. They have been carefully selected for size and fancy points, entirely regardless of relationship."

It must be borne in mind that we are only writing for fanciers; not for those who keep poultry either with a view to killing for table purposes or to the production of eggs. We do not say that even for these purposes in-breeding may not sometimes be desirable; but there is no doubt that, as a general rule, first crosses are more advantageous. The fancier, however, does not regard table or laying qualities as of primary importance. He seeks to attain perfection in certain fancy points, and the more difficult the task of attaining perfection the more attractive is the pursuit of it. Even though the variety which he takes up have certain known characteristics which are easily reproduced, the true fancier is not satisfied with merely reproducing these, but seeks to add new

beauties and new perfections to his favourites. Writing for him we must undoubtedly answer the question which we first propounded to our readers in the affirmative, and declare that the adoption of in-breeding is essential to the success of the fancier. In this view we are supported, as we have always stated, by the recorded results of the methods of breeding adopted in regard to cattle, sheep, and dogs, by what we know of the methods adopted by successful breeders of poultry and Pigeons, and by our own experience in this matter extending over a period of nearly twenty years.

(To be continued.)

### EGGS IN WINTER.

EVERY farmer who knows anything knows that it pays to have eggs to sell in winter, but not one farmer in twenty takes the slightest pains to persuade his hens to lay in cold weather. Many farmers who use common sense in caring for their horses, cows, sheep, and swine, exhibit a wonderful amount of ignorance and stupidity when it comes to managing poultry, and the flocks of twenty or thirty hens, instead of being a source of revenue, barely pay their way in summer and eat their heads off in winter. Whose fault is it? Not the hens' surely. A hen cannot run an egg machine without a supply of raw material to work on. What would these farmers think of a man who sheltered his cow in a rail pen, fed her on straw, let her go without water, and then growled because she did not produce as much milk as when on Clover pasture in June?

A medium-sized egg contains 127 grains of albumen, 94 grains of fat, 13 grains of ash, and 666 grains of water. To those who have never studied these things the amount of water seems large, but it is less than in beef, while the amount of fat and of muscle-forming material is greater than in fat beef. Now does anybody imagine that hens can manufacture such a highly nutritious article of food unless they are provided with plenty of raw material in the shape of egg-making food, and a comfortable house to live in?

It is just as easy to have eggs to sell in winter as in summer, and a great deal more profitable. Don't tell me that it is not natural for hens to lay in winter. It is just as natural for hens to lay in winter as it is for cows to give milk in winter. Give your fowls comfortable houses, and with proper food and care they will lay, because they cannot help themselves.

No live stock on the farm will pay as well in winter as a flock of hens properly managed. Farmers, look to this; turn over a new leaf with the new year, and give your fowls the same care that you give to other stock, and you will never have cause to complain that hens eat more during the winter than all the eggs they lay in a year would pay for.—FANNY FIELD (in *Prairie Farmer*.)

### TOY PIGEONS—HELMETS AND SPOTS.

THESE two varieties are nearly related; we place them before many more popular breeds because they are old-established, and descriptions of them are to be found in the older Pigeon books. The breeding of Toy Pigeons has certainly of late years been carried on in a more scientific manner than formerly, and consequently fanciers are attracted to varieties with many fancy points. Helmets and Spots have few, and have consequently gone out of favour. The "Any other variety" classes, too, at shows are now everywhere overfilled, and judges in their perplexity look to striking novelty and pass over old-fashioned favourites. For a real fancier who loves his birds for their beauty and interesting ways, apart from their exhibition value, there are few breeds of Pigeons which we think more suitable than these. They are agile and light on the wing, good breeders and mothers, and in all Pigeons the contrast between finely defined white and coloured feathers is very beautiful. Our old friend "The Dove-cote and Aviary" says of the Helmet—"The Helmet is about the size of a Nun, or somewhat bigger. The head, tail, and flight feathers of the wings are always of one colour, as black, red, yellow, and I believe there are some blue, and all the rest of the body white, so that the chief difference between them and a Nun is that they have no hood on the head and are commonly gravel-cyed." "The Treatise" says, "They are called Helmets from their heads being covered with a plumage which is distinct in colour from their body, and appears somewhat like a helmet to cover the head."

The Helmets which we have ourselves seen, and which are now occasionally shown, have the coloured head and tail but not the flights; indeed, we do not believe that there are now any to be procured with coloured flights. The head marking must of course

be very "clean-cut," like a Bald Tumbler, though the reverse as to colour. This marking unfortunately leaves some scope for "trimming," and Helmets should not be bought from chance vendors. We once had a Yellow hen which the late Mr. B. P. Brent, a true fancier and a great judge of Pigeons, procured for us from Germany. She was a Crested Helmet—i.e., her head like a Nun, but with white flights, and a very pretty bird. Spots, instead of a coloured head, have a coloured spot over their beaks, coloured tails, and the rest of their plumage white. They are scarcely so pretty as Helmets, but increase the variety of a flight.—C.

**DORCHESTER SHOW.**—Owing to the great snowstorm which prevailed throughout the country last week, our reporter was quite unable to reach Dorchester Show in time to furnish us with a report. Much the same birds will no doubt put in an appearance at Yeovil this week, and we hope to be able to give our readers a full report of the Show there. We fear the storm will have proved disastrous to many birds through exposure to cold, occasioned by the delays in the railway service. We would counsel owners not to send their favourites on long journeys while this severe weather lasts.

### OUR LETTER BOX.

**Pigeon Unhealthy** (*H. A., Manchester*).—Your Pigeon is evidently suffering from a bad form of canker. Cut or scrape away the diseased parts, wash well with Condy's Red Fluid, and touch with lunar caustic. If the inside of the mouth be much affected, a small indiarubber ring should be put on the lower mandible of the beak to keep the parts from touching each other. In that case the bird will have to be fed by hand until the wounds heal, and the ring can be removed. Books such as you want are the "Practical Pigeon Keeper," price 3s. 6d., and the "Book of Pigeons," price 31s. 6d., both published by Cassell, Peter, Galpin, & Co. The latter work is now being published in shilling parts. The Long-faced show Antwerps are the flying birds, but the Short-faced have been known to be good homers occasionally. Homing Pigeons are bred exclusively for flying, not for show purposes, and have been produced by crossing several varieties. The term you refer to is merely local, which carries its own explanation with it; there is no such variety.

**Turkeys not Thriving** (*J. F. Brambles*).—Your Turkeys are suffering from indigestion. Have they plenty of gravel or lime rubbish? If not, supply it at once. A good dose of castor oil followed by soft food moistened with boiled milk, or having a small quantity of powdered chalk mixed through it, will be the best treatment to adopt. If the food has been long in the crop you must soften it with plenty of warm water; have the bird held up by the legs, and gently press the food out through the gullet. This requires to be done rapidly, and care must be taken that the bird is not suffocated by continuing the process for too long a time at once. Afterwards feed for some time only upon soft food.

### REMARKS.

16th.—Bright fine morning, cloudy afternoon, clear in evening; intense cold all day.  
 17th.—Misty and bitterly cold; slight sunshine in middle of day.  
 18th.—Very boisterous, with piercing cold wind and drifting snow all day. Up to 1 P.M. snow 3 inches in depth, 8 P.M. 7½ inches, 9 P.M. 8½ inches; wind decreasing after 5 P.M.  
 19th.—Snow commenced again at 9 A.M., and continued most of the day; high wind in evening.  
 20th.—Bitterly cold but very fine, with much bright sunshine; fog in evening.  
 21st.—Bright, clear, and very cold.  
 22nd.—Few flakes of snow at 9 A.M.; frosty and overcast great part of the day; bright at sunset.

The week has been equally remarkable for low temperature and for deep snow. The air temperature has not been quite as low as in 1860 and in 1867 (6.7° in each case), but the exposed thermometers have been very low. On Monday, before the great snow, the minimum thermometer lying on the snow of the 12th fell to 2.3°; then on the 19th and 20th it was buried in the deep snow, but being dug out and, with several others, laid upon the snow it fell on the morning of the 21st very nearly to zero. The remarkable effect of a covering of snow in keeping the earth warm is shown by the earth at a depth of 1 foot remaining considerably above freezing point, although last year—with much higher air temperatures but without snow—it stood at freezing point for more than a week.—G. J. SYMONS.

## EARLY PEAS.

**H**AVE you picked any Peas yet?" is a question often asked early in the season among rival gardeners, more especially those in charge of comparatively small gardens. Few gardeners like to be much behind their neighbours with their vegetable crops, and friendly rivalry no doubt has done much to stimulate growers to extra exertions in the laudable attempt to excel with all kinds of vegetables, and Peas in particular. In this district it is not the prospect of being surpassed by neighbouring gardeners that incites to extra exertions, but the certainty that if we do not pick early we shall be excelled by the growers for markets, and that too in the open fields. As Peas at all times, and especially early and late dishes, were much appreciated here, it has been my aim not only to have good early pickings from boxes and frames, but also from rows on the south border, before many of the market growers had commenced picking. According to promise I will briefly relate my practice, which, if not novel, has at all events been satisfactory to my employer, and I may say profitable to myself. According to my ideas it is a mistake to grow a few small dishes far ahead of the ordinary outside supply. My object has been to secure a moderate and continuous supply with the aid of boxes, frames, and sheltered positions for at least three weeks prior to the ordinary early crops, and the same results may easily be attained in many other gardens.

With very early Peas in pots I have never done much good, indeed we could not afford the room for a sufficient number to be grown; nor do Peas force readily. At one time our earliest Peas were grown in ordinary three-light frames placed on a slight hotbed, sowing the seed early in January. I may remark, that although we transplant a great number of Peas, they really crop most heavily if sown where they are to remain. Very little trouble in the way of watering and ventilating was taken with those in frames, no attempt being made to force the crop, and useful pickings were the result. Last season the frames were wanted for other vegetables, and our earliest supply was obtained from a sowing made in some old verandah flower boxes. These are about 9 inches wide and 10 inches deep; they were lightly drained and filled with a mixture of chopped turf and soil from an old Cucumber bed. Laxton's Minimum, kindly sent for trial by the raiser, was the variety grown. The seed was sown early in February, and the boxes were placed in a Peach house that was being slowly forced. When the young plants were well through the soil, and before becoming drawn, they were transferred to a cold frame, where they remained till early in April, when they were placed outside the

Peach house close under the front, and protected with mats when necessary. The Peas were very lightly staked to prevent their being blown about; and water was supplied freely, varying with liquid manure when the pods were forming. From these our earliest Peas were gathered, and I was informed that they proved very delicious. Minimum in habit is remarkably dwarf and branching, and should be sown thinly; it is very prolific, and the comparatively small pots yield an astonishing number of sweet wrinkled Peas. I have no doubt it would succeed admirably in 8-inch pots, being treated similarly to those in boxes. Peas when established in pots require liberal supplies of water at the roots, and that is why boxes are preferable; but where pits or frames are available it will be found most profitable to employ them in preference to either pots or boxes.

To follow those grown in boxes we grew a crop in an old unglazed pit, protecting with mats. The variety preferred for this sowing is Laxton's Unique, a dwarf form of William I.; but this, unfortunately, has not found favour with growers generally, consequently it is eliminated from most seed catalogues. I save my own seed, and those who intend growing Peas in frames and cannot procure Unique must substitute some other dwarf early variety. For the future we shall sow the seed in boxes, placing these in a cold frame if sown in January, or in a gentle heat if sown during February. Before the plants become drawn they are in the latter case transferred to a cold house or frame, transplanting into pits towards the end of March. A slight hotbed sufficient to assist the establishment of the plants is previously formed; over this a layer of manure and soil being spread in equal parts, and then a depth of about 9 inches of soil composed of old potting soil and loam from old Cucumber and Melon beds. The lines of Peas extending north and south are placed about 18 inches apart, or three to a light, and between these are planted single rows of spring-sown Early Paris Market Cabbage Lettuce, early Radishes being sown on each side of these, all eventually proving useful. The Peas are staked when planted out (Unique grows about 18 inches in height); they are protected from frosts and heavy cold rains too, as much as possible with mats; water is given at any time when the soil is dry, liquid manure being freely supplied when the pods are forming.

To maintain the supply another batch of plants was raised at the same time as the foregoing of Unique, Minimum, and William I.; and these when well hardened off were, on the first favourable opportunity, planted out, the two former at the base of a west wall, and the latter near a fence facing westward—such sites here proving the warmest. All were staked, and protected with branches of evergreens when necessary, and copious supplies of liquid manure were also given as the crop advanced. Last season in this manner we secured good dishes fully a fortnight in advance of those Peas grown on the south border clear of, but sheltered by, a wall.

The last mentioned is what may be termed our principal early supply, which is obtained by sowing direct, or still earlier if a lighter crop, by transplanting from frames. In our case the latter is resorted to should we be unable early in February to work the soil into good condition. In any case I recommend transplanting where no other early Peas are grown, as a week at the least is gained thereby. Again, if early dishes rather than heavy crops are desired it is a mistake to sow or plant on a very rich loose soil, as under these conditions the

Peas are apt to grow very vigorously, and are later accordingly. I account for the earliness of the field crops from the fact of the seed being sown on comparatively poor soil; and from exposure to the sun and air the plants do not make much superfluous growth. To succeed those transplanted it is necessary to sow more seed of the same varieties either on a warm border or in the open, as early as possible in February; and if the earliest are sown direct another sowing should be made when these are pushing through the soil. As I have before stated, my favourite varieties for the principal early crops are Harbinger and William I., and if either of these are unobtainable, or a third variety be tried, then I recommend Suttons' Emerald Gem.

Some gardeners consider sowing and transplanting Peas a troublesome process, but I venture to assert the amount of trouble necessarily taken is more apparent than real; and that it is less trouble and often more profitable to raise the plants under glass and transplant them than to sow in the border. I am alluding to sowings made early in the year, late autumn sowing being in my opinion often a waste of labour and seed. If it were really necessary to sow in turves, troughs, and even pots, then the case might be slightly different; but after having tried all these methods I have arrived at the conclusion that better results are obtained by sowing in ordinary bedding Pelargonium boxes; and also that it is preferable to sow the seed early in January, and place the boxes in a cold frame rather than in heat later on, followed by the requisite hardening off of the plants. The boxes should have a layer of clean potsherds over the bottom, principally to prevent the primary roots from clinging to the wood, and thereby being much damaged when transplanted. The soil employed should be light and fine; we use fully one-half sifted leaf soil, and from this the roots separate freely, and can be laid-in to their full length. This last is not generally the case with plants raised in pots or turves, and these I find do not so readily establish themselves in the surrounding soil, and owing to the diversion of tap roots do not root so deeply.

When we transplant our Peas, which is usually on the first favourable opportunity in March, a line is drawn, and on each side, and about 2 inches clear, a deep narrow trench is taken out with a spade, as if for laying Box; the plants are shaken out, laid-in singly about 2 inches apart, and the soil carefully worked about the roots. By these simple means rows of strong plants are formed, which are generally too old for the birds to eat, and will grow away without any marked check. They are at once earthed up and staked, and with well-hardened plants no other protection is necessary. If second early or main crop varieties are required early for any particular purpose they can, as a rule, only be had by sowing under glass and transplanting. Last season Webb's Triumph, a main crop variety, so treated was fit for use when wanted—viz., June 29th.—W. IGGULDEN.

#### ROSES ON THEIR OWN ROOTS AND OTHERWISE.

In his review of the "Rosarians' Year Book for 1881" "J. A. W.," on page 49, deservedly draws attention to the able articles of Mr. George Baker. I cordially endorse the high opinion "J. A. W." forms of them. They are certainly most ably written; and as Mr. Baker is known to be a successful grower, a careful observer, as well as a concise writer on matters pertaining to the Rose, his articles may be advantageously read by all who attempt the cultivation of the Rose for pleasure or profit.

With respect to the cultivation of Roses on their own roots, which the reviewer thinks a fit subject for the Committee of the National Rose Society to take up so as to make a list of those varieties likely to do and thrive without the help of a foster-parent, I consider premature. The attempt would, at the present time at least, end in failure or prove very misleading, for the simple reason that the system of growing Roses in quantity on their own roots, especially for exhibition purposes, must as yet be quite in its infancy.

That some Roses do as well on their own roots as on any kind of stock I readily admit, though I should hesitate to give a list of such. *Maréchal Niel* I am certain will not do well on its own roots, and the stocks most congenial to it are the *Briar* and the *De la Grifferaie*. This Rose strikes root most readily, but it is very disappointing in its growth afterwards.

To produce Roses in quantity on their own roots is a very slow

process, consequently it is a question if it will ever become general enough to annihilate the foster-parents of the Rose. Some growers for sale are able to supply plants on their own roots, but I question if they do not send out more thousands on stocks than dozens that have been raised from cuttings. That there are advantages attending this mode of culture in some instances no one can deny, only in the present age of hurry and advancement most growers are anxious for the results of their labour to make its appearance in a much shorter time than can be attained by the slow and tedious process in question.

It is well known that most rosarians have a fancy for some particular stock on which they find their plants do best and make the most satisfactory returns. A great change has been brought about in the number and choice of Rose stocks during the last thirty years, which has most certainly assisted in giving an extraordinary impetus to Rose-growing. Roses judiciously selected on a stock known to be suitable for the soil and situation they are intended to be planted in, and fairly treated, will assuredly make a much more gratifying return than they could possibly do when a haphazard selection is made, and when worked on a stock only suitable for soil the very opposite to that in which they are intended to be planted. If beginners in Rose-growing were only authoritatively guided by any one of our well-known Rose-growers, the results would not only astonish them but afford them much pleasure. It would be altogether wrong to unduly magnify the results likely to accrue from a proper selection of stocks in very indifferent soil, but that good ordinary Rose blooms fit either for garden or decorative purposes would be obtained I unhesitatingly assert.—OXONIAN.

#### THE SEED ORDER.

(Continued from page 66.)

As the Cauliflower season lasts some seven months, and as most people like Cauliflowers, this must be considered one of the principal vegetables. Success here perhaps depends more on management than on the selection of varieties, because it is scarcely possible to obtain seed of a bad variety from a respectable firm now when there are so many good ones in the market. I depend still for the first main crop on the true stock of *Early London*, for although the newer early and reputed early varieties are not neglected, I have not personally proved them sufficiently to depend exclusively on them. I have half an ounce of this, one ounce of *Walcheren*, and two packets of *Veitch's Autumn Giant*. The sowing for the first spring crop takes place during the first week in September, which is later than is advised in any of the calendars I have read. It is made in a warm position out of doors, and as soon as the plants have formed the first rough leaf they are carefully pricked out about 4 inches apart in a frame raised a little above the ground level by means of some rather dry litter, where they remain with as little protection as is necessary till February, then to be transplanted about 9 inches apart in a warm corner, with a plank running along each side of the bed, on which shutters or lights can rest when required. Later on three-fourths of them are carefully lifted with balls of earth, and planted in the open ground, leaving the remainder, which are then 18 inches apart, to be still protected when necessary. The second sowing is made early in February between rows of Potatoes in a warm frame. This sowing consists of the three main varieties—viz., *Early London*, *Walcheren*, and *Autumn Giant*. Another sowing of the same varieties is made early in March where the plants can be protected with glass, and a third and fourth outside during the same month. Two or three sowings consisting exclusively of *Walcheren* are made during April and the early part of May, and the final sowing about the middle of May, when *Early London* is used as well as *Walcheren*.

Of Celery I grow three varieties. *Major Clarke's Red* is the best in quality, but it is neither the earliest nor the hardiest. *Sandringham Dwarf White* is fit to use first, and for standing through the winter I use *Williams' Matchless Red*. The old large-rooted *Chicory* is preferred to the *Whitloof* variety, and the latter is discarded. *Chervil* is in almost daily request and must not be neglected. It is hardy in most positions, and about two sowings will suffice. Of Cress the plain or common is quite as good for common use as the more expensive *Extra Curled* variety. *Ayton Castle* and *Musselburgh Leeks* are used, and one ounce of each is sufficient.

Of Cucumbers I save my own seed, but those who require a variety to depend on during winter may select from *Masters' Prolific*, *Rollisson's Telegraph*, and *Dickson's Favourite*. Ridge Cucumbers and Gherkins are not grown, the small fruits from those grown in houses and pits answering very well for pickling purposes.

**Lettuce and Endive.** Early Paris Market Lettuce is valuable, and if seed is sown early in February in a warm dung frame, and the young plants transplanted carefully to another frame as soon as they are large enough, will often come in before the autumn-sown crop of Cos Lettuces, but it must not be allowed to remain in the seed bed a day too long. The only other Cabbage Lettuce I use generally is Tom Thumb, which is very useful both for autumn and early spring use. Alexandra White Cos is good for summer weather, but the Black-seeded Bath Cos is the most important of all, it being indispensable in spring, autumn, and winter, and when we happen to have a bad summer, it is also then one of the best to depend on. Two ounces of the last-named and a less quantity of each of the others are sufficient for my purpose. The Improved Round-leaved Batavian Endive is a great favourite and is used largely. One sowing is made about midsummer, and another three weeks later. The Green Curled variety is also sown at the same times.

Of Melons the Cashmere is preferred, but it is a difficult one to grow, cannot be had very early, and will not do in a frame, therefore I should not recommend novices to try it. Eastnor Castle is one of the easiest Melons to grow, and although inferior to the Cashmere in quality, it is better than most other varieties, and would satisfy those who have not tasted a well-grown fruit of Cashmere.

Of Onions I grow White Spanish for the earliest, Danvers Yellow for the main crop, Silverskin for pickling, and Giant Rocca for autumn sowing. I have 1 lb. of seed of Danvers Yellow, and 4 ozs. each of the others.

Of Parsley I grow the Fern-leaved and anybody's splendid Curled, and of Parsnips a good stock of Hollow-crowned, of which I require 1 lb. of seed. Radishes are not much in request, but a few of Wood's Early Frame are used in the spring for sowing on dung beds between Carrots, &c. Salsafy is much used by some cooks during winter, and is so easy to grow that it is always advisable to have it in all large establishments. The last week in April is soon enough to sow it, and 2 ozs. is sufficient.

Of Savoys, the Dwarf Green Curled is the principal, and Drum-head makes a good succession. These vegetables are seldom planted out sufficiently early. They are too late; they follow any but the very early Potatoes, and where ground cannot be had soon enough for those named it would be better to use some variety which comes in quicker.

Spinach is an all-the-year-round vegetable, and therefore must not be neglected. I use one quart of the Round or Summer Spinach, and double that quantity of the Prickly or Winter variety. The last-named has done better with me this season than ever it did before, and I attribute the success to the large quantity of burned clay which was worked into the ground. Tomatoes, too, are in daily request all the year, and I find none so good as the old Orangefield Dwarf for my purpose. I consider it, too, the best flavoured of the Tomatoes I have tasted, and I fancy I ought to be a tolerably good judge, for I prefer Tomatoes to Peaches. This variety can scarcely be obtained true to name now from the seed shops. In the Tomato trial at Chiswick a few years ago I saw several named Orangefield Dwarf, but only one or two plants of the true sort. I keep my stock by cutting.

Early White Dutch Turnip is used for the earliest, Veitch's Red Globe for the main crop, Chirk Castle and Orange Jelly for winter.—WM. TAYLOR.

I HAVE been unconsciously following Mr. Taylor's plan in ordering seeds; and I am proud that I have followed so good a man, even in such a small matter, as I have a high opinion of him, although I only know him by his writings in the Journal. After examining the seed catalogue, pencil or pen in hand, several novelties are generally included. Seeds were so expensive last year that novelties had to be excluded. I next ascertain the cost of the seeds, and if I find the novelties have increased the total price too much, they are then reduced in number. These, with fresh sorts, are carefully tried by the side of well-known varieties, all their points are noted, and a private mark is placed against each in the seed catalogue and my diary. Therefore my notes during the year leave me scarcely anything to do but mark the quantities required. One of my employers thought he could purchase seeds himself at less expense, so he ordered a collection. At the end of the summer I had several of the packets left untouched; some of them were kept two or three years, they were then thrown away. Of other sorts that we had a greater demand for there were not nearly enough. The bill for these extra seeds during the year was almost as much as the collection cost. I have no doubt that collections are very useful for people that do not study gardening, and small gardeners who have not confidence to order seeds in the usual manner, from a lack of knowledge of the

different varieties that are now so numerous, and to many people bewildering.—J. L.

#### CANDOLLEA CUNEIFORMIS.

A LARGE bushy specimen, 4 feet high and a yard in diameter, of this rare old plant is now flowering in a cool greenhouse in the Botanical Gardens of Trinity College, Dublin. In foliage and flower it so nearly resembles an Azalea that many visitors are deceived into believing it to be one. Our plant is in bloom for six months out of the twelve. Cuttings root in a cold frame, but the process is a very slow one. Some inserted last May have only just emitted roots, and I am half afraid that the severe weather (22° below freezing) has been too much for them, the frame being only protected with a mat. Some, however, appear to be alive, and cuttings of *Hypericum chinense* (or *H. monogynum*), and *Calceolaria fuchsifolia* × *Pavoni*, however, look

Fig. 20.—*Candollea cuneiformis*.

none the worse for the low temperature above named. This *Candollea* will grow well in a cold greenhouse from which frost is excluded, and would doubtless be hardy in the Scilly Isles and in any other peculiarly sheltered parts of Britain. The leaves are of a shining light green colour; the flowers are bright yellow. Both flowers and foliage are represented of the natural size in the accompanying illustration. The plant is a near ally of the *Hibbertias*, and was introduced to this country from New Holland rather more than half a century ago.—DUBLINENSIS.

#### NATIONAL ROSE SOCIETY.

AMID the gloom and chilly surroundings of this most inclement season, it is cheering indeed for anyone who has a love for Roses to think of the condition and the prospects of the National Rose Society. These indeed may be said in a double sense of the word to be truly "rosy;" indeed, so far as my experience of Rose societies goes, I never knew one before exhibit such vitality or have such fair prospects as this Society. But someone may say, "This condition is what one would expect and to what a national society, be it worthy of the name, should as a matter of course attain." True indeed, but it is not always that a name commands success. There are, however, certain conditions which if a society fulfils it may command success, and I think the National Rose Society does fulfil these.

First, justice. It is just in its dealings to all men with whom it comes in contact. Provincial Rose societies are met with liberality and encouraged in every way. Exhibitors great and small are treated in the fairest way. There is no favour shown to great growers, whilst small exhibitors are treated with disdain. The claims of all are allowed; and the suburban grower, who under great difficulties manages to grow a few Roses, knows that his six will have as good a chance of winning a prize as the big nurseryman's seventy-two.

2. While it is comprehensive in its character it also is ubiquitous

—goes everywhere : in fact the motto of the famous regiment of the Royal Artillery, "*Ubique*," may be applied to it. In north and south, east and west, either now or in future years, will the National Rose Society hold its shows. This year, for example, there are to be three great shows—viz., one in the south and two in the north. At Sydenham, under the glass of that famous Palace which has seen so many noble exhibitions, the southern men will come to show how Exeter, Colchester, Cheshunt, Hereford, Canterbury, Slough, and a hundred other places can grow Roses which will be the pride of all who are fortunate to see them ; while at Sheffield, that dingy smoke-enveloped town, the brave men of the north will prove how they can battle with difficulties. Manchester, too, determined not to be left out in cold for one year even, have invited us again to hold a show at their famous Botanic Gardens ; and we have indeed good reason for believing, that whatever town may claim our provincial shows in future years, Manchester will always invite us. Next year, that lovely city once the most fashionable inland watering place in this fair land, and now as ever the most beautiful city—Bath, will once more see a grand Rose show held in her gardens ; and year after year we doubt not other towns will invite us, so that we shall prove indeed our claim to our motto, "*Ubique*."

3. But all this success would be marred if our finances were in bad order, if we were not paying our way, or had to face the coming season with dread and foreboding. But in this respect fortunately we are in a most excellent position. We have a good balance in hand, and if we have only a good Rose season, fine weather, a genial spring, and a hot summer we shall hope to add to our balances.

4. Then again, we are a united body. When the Committee meet a smile is on every face, a warm hand-shake is exchanged on all sides, and each one settles down to work with but one wish in his heart—to do his best for the Society, to encourage Rose-growers, to animate the minds of all with an eager desire to improve the flower we love so dearly.

"*Floreat Rosa*" we say, and then do our best to make it flourish ; and I am sure the Rose Journal, or rather the Editor thereof, will re-echo the cry, and do all in his power, as of old, for many years, by giving good reports of the various shows, to encourage Rose-growing ; and I do not think there are many subscribers to this estimable weekly who will not wish us well.

Go where I will I hear of fresh men who are heartily going-in for Rose-growing. But no county seems to be advancing with greater strides than Sussex. I once held the humble position of junior curate at a large town in Sussex, and when there no one grew Roses except as garden flowers. Now I know of four large growers and exhibitors, one of whom is on the Committee of the National, and only the other day I heard of a gentleman who lives in a large park who is making it the "business of his life to grow Roses fit for exhibition."

Although no longer able to carry the long green boxes into the tented field, my love for the Rose is not diminished, nor ever will it be. As a member of the Committee, as a judge it may be, at all events as (not a critic, that is too harsh a word) a reporter of the varied glories of our shows, I will ever do my best to promote the welfare of the Rose.—WYLD SAVAGE.

As in your notice of the last meeting of the General Committee of the National Rose Society it was stated that I had been deputed to visit Sheffield and confer with the authorities there as to the arrangements for the forthcoming Exhibition, I am sure that many of our members will be glad to hear how matters are progressing. I have never for a long while travelled on so cold and bitter a day ; three times during the journey we cleared the windows, and three times they were again completely covered with frost. But the warmth of one's reception made up for any of the inconveniences of the journey, and a bill of fare placed before me which would satisfy the most voracious lover of the Rose or the most ambitious exhibitor, for in addition to the hundred guineas which they contribute to the schedule they have made up a special fund of nearly £130. A considerable portion of this is for prizes to local exhibitors—that is, for those residing within thirty miles of the Town Hall, Sheffield, and for bouquets of Roses ; but I may specify that besides these the Mayor of Sheffield presents a ten-guinea cup in the nurserymen's class of seventy-two, and the Master Cutler another cup of the same value in the amateurs' class of forty-eight. The President of the Botanic Society gives another ten-guinea cup for the best collection of Roses in pots, the town of Sheffield two five-guinea cups and a prize of £5 for the best seedling Rose, to be called the "Rose of Sheffield," so that altogether a schedule that has never been equalled at any provincial Rose show will be set before exhibitors ; the total value of the prizes offered being nearly £270.

I may also add that in every way it will be the desire of the Committee of the Botanic Society to consult the comfort and pleasure of the exhibitors. Arrangements will be made whereby exhibitors and their assistants can procure refreshments at moderate charges

from an early hour in the morning. Vans will be in readiness to convey the boxes from the stations, and the Judges will be invited to a dinner to be held in the evening. As already announced, Canon Hole, the President of the Society, will deliver a lecture on Roses (to be followed by discussion) in the gardens at four o'clock, so that everything has been done to endeavour to make the meeting a success. Thus the opinion of those who so strenuously desired that Sheffield should be the place of rendezvous has been abundantly justified by the preparations that have been made to receive the Society. Two things will be wanted to achieve that success—Roses to show, and a fine day to see them ; both of these are beyond our management, but let us hope we may have them.—D., Deal.

## THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 46.)

By the staining process it is shown that the fluid contained in the roots is devoid of oxygen in its free state, but that it acquires this condition at the collar where it becomes exposed to the atmosphere. Now the chief materials absorbed from the atmosphere are oxygen, carbonic acid, and water, and possibly small portions of nitrogen ; but these elements in entering pursue a totally different course to that absorbed by the roots, for, instead of taking an upward course, they proceed directly across towards the pith inwards, as may be proved by staining during active growth. Fill a wineglass with small shot, and it will still hold a considerable quantity of water in addition ; the shot, not fitting together but leaving angular cavities between them, provide openings which in the cellular tissues of plants are termed "intercellular spaces," and are thus organised as a provision for admitting the nutrient sap to all other parts of the system where the upflowing sap does not appear to reach. But this is not all. These spaces are in communication with the epidermal cells and hairs, by which they are fed from the external atmosphere. Let a small piece of any fine root or rootlet containing hairs upon the surface, together with a fragment of any hairy leaf or stem, be placed in a drop of water upon a glass slip, and then be covered with thin glass and submitted to the microscope. Next, with a pointed matchstick dipped in the magenta dye touch the upper edge of the cover, so that the stain may gradually spread within. On closely watching its entry the tips of the hairs upon both leaves and roots will be seen to be the first to accumulate the colour, and that it will then extend inwards into the intercellular spaces, of which these hairs are extensions, apparently with a view to increasing the area of the absorbing surface.

The providing of this twofold source of supply is only another manifestation of that supreme wisdom of the Creator, which, like the bubble of air in the egg, is too simple in its design not to be misunderstood, but which, like Columbus with the broken egg, when explained is too evident to admit of the slightest doubt ; in fact, it is scarcely possible to conceive how the desired ends could be attained in any other way. By the aid of staining it is shown that the fluids taken in at the roots find their way up through certain passages only in the stems and stalks, and ramifying veins of the leaves, and up to the extreme margins of the latter, whence the superfluous moisture is given out again back to the atmosphere, as may often be seen early in the morning in a vinery after a night's rain, when the leaves will be found to be all fringed at the edges with small drops of water like pearly dewdrops. Now, as these longitudinal passages are in immediate connection with the growing tissues, it is obvious that it is from this source the woody fibre, starch, and other solid tissues derive their materials of increase ; while, on the other hand, the carbon, oxygen, and water, &c., derived from the atmosphere and insinuating themselves between the individual cells of the parenchymatous tissue go to the production of sugar, gum, wax, resin, the essential oils, and other similar products. In the grafted tree we find the stock furnishing the crude material ; but it is the electro-chemical action occurring between the pith and the bark of the scion that converts this primary upward current in combination with the preceding supply from the external source, crossing the former into the special compounds peculiar to the particular variety in question. Now as all growing cells have, like the egg, one or more nuclei or negative centres of growth, these fed from the intercellular spaces, when the parent cell shall have attained its full growth, then take up the action and follow in like course, and so on by repetition of division or multiplication stems and leaves acquire their full size and density. But as the electrical action is between the pith and the bark the diaphragm necessarily forms longitudinally or in the direction of the plant's extension.

In the consolidation of the albumen at the centre of the divisional wall C of fig. 96, the material became at length so hard and horny (or almost bony even) as to intercept the action ; but had

there been an extraneous supply of moisture entering from without, this doubtless would have kept the part sufficiently moist to allow the continuous passage of the force. Now in plant growth, the upflowing sap is ever during growth undergoing this consolidation, but its undue solidity is prevented by the constant accession of moisture from without. In its upward course the upflowing sap is thus being altered in its composition by the transverse electro-chemical decomposition in proportion to the distance it has to traverse relatively. "Mr. Knight," says Sir Humphry Davy in his "Agricultural Chemistry," "made numerous incisions into the alburnum of the Sycamore and the Birch at different heights; and in examining the sap that flowed from them, he found it more sweet and mucilaginous in proportion as the aperture from which it flowed was elevated." Sir Humphry Davy states it to be his own opinion "that the cambium (between the tree and the bark) from which the new parts in the trunk and branches appear to be formed, probably owes its powers of consolidation to the mixture of two different kinds of sap, one of which flows upwards from the roots, and the other of which probably descends from the leaves." It has, however, as previously observed, never been possible to detect by staining any descending sap-action whatever. Still, the admixture of two different kinds of fluid is an undoubted fact, although the source and intent of the second supply does not appear to have been rightly suspected." Sir Humphry Davy then goes on to observe that "the increase of trees and plants must depend upon the quantity of sap which passes into these organs; upon the quality of this sap; and on its modification by the principles of the atmosphere." From this asserted "modification by the principles of the atmosphere" it is sufficiently evident that to this operation much import was attached, without, however, any attempted explanation of in what these principles consisted. In supplying these deficiencies the existence of an "electro-polar" arrangement of the structures offers a very intelligible explanation of the means made use of, for their polarity could be effective only when responded to by the electric polarity of the atmosphere; and as was experienced in the plant-case previously noticed, when this polarity was upset, plant growth ceased to flourish and fungi took its place, a circumstance throwing much light on the production of mildew as well as on the cultivation of Mushrooms.—W. K. BRIDGMAN, *Norwich*.

#### MUSSÆNDA FRONDOSA.

AMONGST winter-flowering plants the above should be grown; in fact, it is worth a place in every stove, however limited the collection of plants may be. It is an evergreen plant of sturdy habit, and can readily be grown into a good bush. When well grown this plant is far more attractive than the white Poinsettia. The flowers are produced in terminal racemes, and are a pleasing yellow colour, while the bracts are pure white. The bracts and flowers are freely produced, and a good bush is very imposing. They are produced in quick succession; when one batch is gone the plants make a slight growth and more flowers and bracts are produced. It will flourish in an intermediate temperature, but its growth is not so rapid nor its foliage or bracts so fine as when in a stove.

This plant is easily propagated by cuttings in spring if the ends of the young shoots are taken off, and either inserted singly or a number round the sides of a 5-inch pot, which should be well drained and filled with equal parts of peat and sand, with a layer of the latter over the surface. It is not necessary to take the cuttings with a heel. Plunge the pots in the propagating frame, and if bottom heat can be given it is better, although the cuttings root readily under the shade of Cucumbers and Melons if covered with a bellglass. When several are inserted together it is essential to attend to the young plants as soon as rooted before the roots become matted.

Pots two inches in diameter should be the size first used, and when the young plants are established in them the points must be pinched out to cause a branching habit, and to form little compact bushes. Potting should be attended to from time to time as the plants require it, never allowing them to become rootbound until they receive their final shift, which entirely depends upon circumstances and conditions. If large specimens are required good plants can be grown in 10 or 12-inch pots, but for ordinary purposes 5 and 6-inch pots are large enough. Stopping should not be attempted after August if the plants are required for autumn decoration. It is well to keep specimens growing on until they attain the desired size. Good drainage is essential. *Mussaenda frondosa* does not appear particular as to soil, and thrives well in rich loam, a seventh of decayed manure, and a little leaf soil, or in loam and peat equal parts, with a good quantity of coarse sand to keep the whole porous. The soil should

be pressed rather firmly into the pots, as the plant is of a woody nature and has rather fine roots.

Staking and tying is not necessary if precaution is taken, as the plant grows, to keep the shoots properly pinched. A few stakes might be of advantage in the case of a specimen to fasten the shoots to for the purpose of forming the base, but when once formed the stakes can be dispensed with. Liberal applications of water should be given while the plants are growing both at the root and upon the foliage, and after the final potting and the pots are full of roots, liquid manure may be freely given, and occasional doses of root water, which greatly invigorates the plants and tells considerably upon the foliage and improves the colour of the bracts.

During the summer the plants should have a place as close to the glass as possible, and air should be allowed to circulate amongst them freely, closing the house in which they are grown early in the afternoon, and syringing the plants at the same time. Shade is necessary during the hottest portion of the day. During winter the plants succeed well in a temperature of 60°, and after well ripening appear to grow and bloom continuously for a time, after which they can be pruned and started again. For ordinary decoration young plants annually raised from cuttings are preferable.

*Mussaenda frondosa* is subject to most insects that infest stove plants, although I have never observed mealy bug upon it. Spider or thrip can be kept down by the use of the syringe, and if scale does not trouble them much. The young foliage is very impatient of fumigating, and is quickly injured however carefully the operation is performed. The plant is well suited for associating with *Calanthe Veitchii* and *C. vestita* when in flower.—WM. BARDNEY.

#### THE VEGETABLE SUPPLY FOR TOWNS.

I AM particularly pleased that my words on this subject have drawn the attention of several able writers, and so led to a discussion. Sometimes in papers and periodicals there are discussions on very frivolous subjects which cannot possibly result in any good, but here is one connected with the health and food of the people; also it is connected, on the other hand, with—so I deem—the advantage and increased prosperity of the food-producer. The subject, then, is worthy, for it is one to benefit producer and consumer.

Next I would observe that it is easy to write in such a general way as to please readers, or at least a way unlikely to provoke criticism; it is also easy to write, too, so recklessly as to be needlessly irritating. I desire to do neither; but I am heartily gratified when what I have happened to write sets other men thinking, produces sensible replies, wholesome criticism, or new useful remarks. I would infinitely rather have writers dissent strongly from me on a useful subject—one calculated to benefit men, and still better women, and best of all children—than that no notice should be taken and the matter be allowed to drop out of sight.

I will first notice the words of Mr. John Wills—and by the way let me express the pleasure I feel in seeing his once well-known name in the columns of "our Journal," from which it has disappeared for more than ten years; it is a real pleasure, I assure him, to see his name once again. During the eighteen years I have been a writer so many contributors, once so well known, are gone, either into the silent land or have dropped their pens, that it is quite refreshing to find one at least reappear. I am glad Mr. Wills has been with us in feeling all along. I am thoroughly gratified that he agrees so much with me in regard to the future of gardening. I fear, however, that the ornamental must for a while be in abeyance to the useful; that the vegetable must take precedence of the flower. When agriculture revives then I shall hope to see the bonny faces of our farmers' daughters and the comely forms of their mothers at (may they be the universal) parochial flower shows; but no one, save those living among them, can know the terribly low financial condition of the south and south-western farmers.

I have last week dismissed all thought of London and the London supply of fruits and vegetables; I thought not of the metropolis. Neither am I sure that peasant proprietorship would do in agricultural matters; but this I am sure of, that it would be to the advantage of landlord and tenant if larger gardens were in the possession of the industrious poor, the owner adding on land, say from half an acre to an acre, and planting part of that land with fruit trees. He must be at that first expense, and in ten years' time benefit will come to his property.

The very first sign I have known in a cottager desiring and trying to improve himself is the wish to have a garden. Tobacco, beer, public house, slatternly wife, and broken furniture—these

go with the man who has no garden and who desires no garden; but if the desire comes there is hope of and reason to expect a change in him and in her for the better. None are so utterly extravagant as the very poor. When a man improves and prospers he becomes more prudent in money matters; so I say, Help him to improve, landlord. Then when improved he becomes a better citizen, a happier more contented man; his children better fed, and tidiness takes the place of dirt and discord. Another reason why more land may with advantage be given to a poor man is, that for his class he is now well off, and can afford to buy tools; the farmer and landlord, for their respective positions, are far poorer than the able-bodied labourer. Again, in pleading for an increase of gardening in the country and around country towns, there would be no cause of jealousy in the market gardener near London, because there the supply is greater than the demand.

I have some knowledge of Birmingham, some also of the cotton districts, and unless things are improved there is a deficiency of vegetable supply in both, and to my mind no faces are more sad to look at than a Birmingham woman's and child's of the lowest class. In the cotton districts of Lancashire bad cookery is the rule among the mill hands. When they are prosperous it is all the frying-pan with ham and eggs in it—well enough for a change, but unwholesome as a regular diet. My argument is, Supply will raise demand. If the local papers are led to notice the many gardens around a town, and the larger supply of fruit and vegetables, and as all now read newspapers, I hope the vegetable would go into the frying-pan with the bacon and ham. Mr. Wills tells us he has done something to advance gardening for "the benefit of his fellow men;" let others try and do the same. As gardening advances among the poor vice receives a check. The man who works on his land during the evening cannot be at the public house.

In regard to the communication of Mr. Iggulden of Orsett, Essex, who in parliamentary language says "he desires to move an amendment to my address," his words refer, as naturally they would from his nearness to London, to the London market gardens, with which I have shown I have nothing to do. One word in regard to my Cornish critic, Mr. W. Roberts of Penzance, who contributes a short but useful article. He says Onions are not in favour with Cornish gardeners; that of course may be. I rather think they would find a more extensive sale in large towns where there is a great artisan population. One thing I am sure of, they are excellent additions to diet. I often eat a supper of stewed Onions, and so do my family. Mr. Roberts mentions Parsley as a profitable crop—one I should not have thought of—hence showing the advantage it is to set many pens to work. Asparagus he also mentions. This might appear oftener on the tables of the better class, and not be regarded as merely a rich man's vegetable; it is also very wholesome. Celery, again, is, if eaten slowly, of a kindly aromatic nature, good for man and of benefit to those suffering from rheumatism. There is one other, hardly vegetable, the humble Watercress, "the only indigenous weed which is thoroughly wholesome," as a London physician remarked to me. But who gets enough Watercresses brought to his door? I would have carts go regularly through every street, and particularly the back streets of our towns, and vendors carry to the doors baskets tastefully set out with specimens of all the vegetables for sale, not forgetting the humble Watercress.

I thank my critics for their kindly and able remarks, and I ask for other pens to be set to work, for I do believe good will arise. A little thought is like a little seed, many thoughts like many seeds, and all good thoughts are productive of good; but as seed must be sown, so thoughts must come to words. At present I will say no more, only to remark that the high price of meat should itself cause the thrifty to look out for other and cheaper food. Where shall they find it? I answer, In using in far greater quantities wholesome nutritious vegetables. Many people dislike Parsnips. Why? Because as children they were not brought up to eat them. Yet a pig will do better on Parsnips than on Potatoes. A horse will do far better on Parsnips than on Carrots. Children naturally love sugared things, and sugar is abundant in the Parsnip. It is custom, and custom only; thus our ancestors ate pease pudding habitually, now few people eat it since Potatoes came in. Custom again. In an advancing civilisation I want reason to rule in matters of diet, not custom.—WILTSHIRE RECTOR.

UNQUESTIONABLY this is a subject of great importance, and it has to be considered in so many aspects and is governed by so many circumstances that it is only natural that there should be a considerable divergence of opinion in regard to it. Animated by the best possible motives, and impelled by a desire to benefit both producers and consumers of vegetable produce, "WILTSHIRE RECTOR" advocates the cultivation of garden crops on farms.

Mr. Wills, who is entitled to be listened to with respect both as a practical cultivator and a successful business man desirous of benefiting his fellow men, appears to be much of the same opinion as "WILTSHIRE RECTOR." A correspondent, "W. P. B." (p. 44), and Mr. Iggulden (p. 64) hold different views, and they appear to have very good reason for considering that the vegetable supply near London already exceeds the demand. I am of this opinion; and knowing something of market gardening, although not now engaged in that vocation, I feel that I can approach the subject without prejudice.

"WILTSHIRE RECTOR'S" remarks on page 1, the general tone of which has been so much and deservedly admired, did not, it appears, apply to London and the sources of its vegetable supply. No one who travels through the market-gardening districts within twenty miles of the metropolis can fail to be struck with the plethora of vegetables, and to observe acres and tons of produce decaying in the fields, and I am of opinion that this is to some extent an index of the state of the country generally. Not long ago I visited the Saturday night's vegetable market in a county town in the midlands, and, as some of the vegetable growers of the district were known to me, I had no difficulty in becoming acquainted with the vegetable supply and demand there. One of these men in answer to an inquiry said, "Talk about agricultural depression; but if the farmers are worse off than we are they are bad indeed. It is only by working every hour of daylight that I can live; saving a little money is out of the question." This was the remark of a man as steady, industrious, and with as much practical knowledge of market gardening as most men. Another man equally steady and industrious, but who had not been "brought up" to the business, said in answer to the question "How are you getting on?" "On! I'm sorry to say I am not getting on at all. I am going back, and shall have to get out of this before I lose what little I have." This man had been in business between two and three years, and was longing to again become a gentleman's gardener. "Look round the market," said this man, "and judge for yourself whether half the vegetables can be sold." I not only looked round then but later, and found that quantities were *not* sold, and could not be sold at any reasonable price: in fact they could not be sold at all. "We could manage," said my informants, "if it were not for the Londoners; but when they send tons at a time down just a week before our stuff is ready they dish us completely and we can't help ourselves." There is a great deal of force in that observation; there is no sentiment about it, but it is a stern, hard, business fact.

Further north, in one of the largest manufacturing towns, I have a friend who is a greengrocer. On noticing his excellent vegetables—Lettuces, Cauliflowers, French Beans, &c., early in the season, he remarked, "They are all Londoners. The growers about here don't put stuff enough in the ground; besides they are too late, and London grades sell the best." I knew before he told me that the vegetables I was examining were grown in the south. I have seen tons of them sent off from the London vegetable grounds, the railway companies sending a dozen large vans into a field at night, which are sent away loaded before daylight the next morning. What chance have the local midland and northern growers against a system—a perfectly legitimate system—such as this? and what chance—I ask the question in all seriousness—have farmers who "take to" vegetable-growing anywhere against these practised cultivators and born marketers with their splendid land and keen business aptitude?

If vegetable-growing is the sheet anchor of farming the farmer's case is hopeless. The advice given by well-intentioned M.P.'s and public men generally, looks well enough "on paper," but put into practice in the fields it is found wanting. The plough cannot compete with the spade in vegetable culture, and farmers cannot "pick up" in a year or two the requisites of successful market gardening, while it is not in the nature of things that M.P.'s can teach them. Still, farmers have one advantage—if they cannot sell their Cabbages, &c., they can give them to their stock, which is what purely market gardeners cannot do.

Mr. Wills' admirable suggestion on page 63 to enlarge the gardens of cottagers in the country is another matter. These people could both grow and sell produce cheaply, and it is cheapness with quality that creates a demand for a commodity; and they can also deal with the consumers, which is a point of great importance, for whatever profit is yielded by vegetable culture the salesmen and middlemen get the bulk of it. Until there is a much greater consumption of vegetables it will not, in my opinion, be sound policy to induce farmers to cultivate them largely—at least not safe for the farmers.—AN OLD HAND.

PRIZES FOR THE IMPROVEMENT OF ASPARAGUS CULTURE.—With a view to improving the culture of Asparagus throughout

the United Kingdom, it is proposed to give a series of annual prizes, extending over a period of seven years. These prizes will be given in London, Dublin, Edinburgh, and the north, south, and west of England in different years. The first Exhibition will be held in the south-eastern counties and in Kent, at Tunbridge Wells, in the horticultural tent of the Exhibition of the Bath and West of England Agricultural Society, which opens on the 6th day of June, 1881. The following prizes are offered for the first year's Exhibition, and are open to growers in any part of the United Kingdom:—*Prizes for Gardeners in Private Places.*—For the best bundle of Asparagus grown by the exhibitor—first prize, £4; second, £2 10s.; third, £1 10s.; fourth, £1. The bundle of Asparagus is to consist of sixty heads. The prizes will be given to the largest Asparagus, provided it be in all other respects unobjectionable. Prizes will not be given where, in the opinion of the Judges, there is no merit. The Asparagus must be free of earth, and the bundles will be opened by the Judges in all cases where they think it well to do so. No imperfect or double heads will count. *Prizes for Amateurs not Employing any Regular Gardener.*—For the best fifty heads, £2 10s.; second prize, £1 10s.; third prize, 15s. Grown by the exhibitor. *Prizes for Cottagers.*—For the best twenty-five heads grown by the exhibitor, £1 10s.; second, £1; third, 10s.; fourth, 5s. *Prizes for Market Growers.*—For the market grower who shall exhibit the best three bundles, each containing one hundred heads, £5 5s. This prize is offered by the Bath and West of England Society, and is open to growers in any part of the United Kingdom. For the market grower in the county of Kent who shall exhibit the two best bundles of Asparagus, each containing one hundred heads:—First prize, £3 3s.; second, £2 2s. These prizes are offered by Mr. Samuel Spalding.

#### FLORISTS' AND POPULAR FLOWERS.

**AURICULAS.**—The cold frames containing our plants have been covered with mats for more than a fortnight, but the plants have sustained no injury. They will be looked over now, and have all decayed leaves removed and the surface of the soil stirred as needed. The plants generally commence fresh growth during February, and more water will be required; still it must be applied cautiously, but never in dribbles to moisten the surface and leave the roots dry below. Towards the end of the month an inch or so of the surface soil must be removed from the pots and a fresh and richer compost added. A compost of half turfy loam and the remaining half decayed cow dung and leaf soil is suitable; and rooted suckers may also be removed at the same time and potted. If the surface dressing is delayed until the roots from the collars of the plants have penetrated the soil they do not readily take possession of the richer compost. The work should therefore be done in good time, and water must be carefully supplied afterwards.

**CARNATIONS (PERPETUAL).**—In order to have a good display of these valuable plants for autumn or winter decoration, cuttings or pipings should be inserted in pots of light soil, and placed in a temperature of 60° to 65°. In bottom heat the cuttings will root more quickly. If there is any scarcity of cuttings of any variety place the old plants in heat, which will assist the growth. The small side growths are the best, but stronger will also strike freely if the lower pair of leaves are carefully removed. Miss Jolliffe, Covent Garden Scarlet, La Belle, A. Alegatière, Celestial, Guelder Rose, Proserpine, Prince of Orange, and White Swan are all good varieties.

**CINERARIAS.**—Plants flowering or approaching that condition will need a temperature of 40° to 50°, and should be well exposed to light to improve the colour. Those producing their flower heads may be assisted by liquid manure, and if the plants are in comparatively small pots it may be used every time they require water, being careful to give it in a weak state. Shift later plants into the flowering pots, employing good loam with about a fourth of thoroughly reduced leaf soil or manure, which is suitable for most quick-growing plants. Fumigate moderately upon the first appearance of aphides.

**CALCEOLARIAS.**—These require similar treatment to Cinerarias, both delighting in a tolerably cool atmosphere and little fire heat; at the same time frost is injurious to them. Calceolarias thrive well if placed on a shelf near the glass; and where the best strains of these are grown they give a display during the early spring months scarcely equalled by any other plant, and form a good succession to the Cineraria. Aphides are often very troublesome, and require frequent attention to destroy them.

**CYCLAMENS.**—These are amongst the most useful winter-flowering plants, being general favourites from the length of time they remain in bloom and their suitability for cutting. A small

house or pit, where they can be near the glass and have an intermediate temperature, is most suitable for them, and they then well repay any attention bestowed upon them; but where they must be grown with other plants a good light position should be afforded them, and they must receive every attention in watering, alternately supplying weak liquid manure. Some of the hardy Cyclamens grown in pots and removed to the greenhouse in autumn are very pretty. *C. neapolitanum*, *C. Coum*, and *C. ibericum* so treated are now in flower.

**DAHLIAS.**—Where it is desired to obtain a good supply of any variety the roots must be placed in heat. To effect that increase take the cuttings which will soon be produced if the roots are in a warm position, and insert them in a little bottom heat, a temperature of 50° to 65° being suitable. They will quickly strike, and may then be potted off. Most of the Pompon varieties are so useful for decorative purposes in the autumn months that gardeners would do well to give attention to them. The varieties White Aster and Little Dear are very beautiful. We grew a large collection of them last year, and they were admired by all who saw them. The Cactus Dahlia (*D. Juarezi*) has attracted much attention during the past two years; the peculiar spreading form of the florets combined with their brilliant colour will soon cause it to become a general favourite. Paragon, lutea, coccinea, and other single varieties will also be much sought after this season.

**GLOXINIAS.**—Seed of these favourites may be sown now, and if the young plants produced are grown rapidly on they will, in the majority of cases, afford a good late autumn display. Formerly this plant was looked upon only as a summer-blooming plant, but now the season of its flowering is very much prolonged by raising a collection from seed and by resting the old plants at different periods of the year. The seeds are very small, and cannot endure heavy and careless watering. Sow them on the surface of some finely sifted soil in pots about three parts filled, placing a piece of glass over the pot to prevent rapid evaporation; or a little moss over the seed answers the same purpose, only it must be lifted before the seedlings become drawn.

**FUCHSIAS.**—Plants of these in heated structures will soon commence growing. When they have grown about an inch the greater part of the old soil should be shaken from the roots, placing the plants in smaller pots, employing a moderately light soil to which leaf soil and silver sand have been added. Early vineries or Peach houses are well suited for starting Fuchsias. The young growths afford excellent cuttings for a healthy stock of young plants for autumn blooming. Old exhausted plants may be destroyed after furnishing a sufficient stock of cuttings, or all the side growths may be cut away and the top growths encouraged to form standards, in which form they are very suitable for arranging with other plants when in bloom. Syringe them freely while growing.

**LILIUMS.**—Some of the earliest-flowered plants of *L. auratum* and *L. longiflorum* will be starting into growth, and must occupy light positions to insure a sturdy growth. If any have been placed beneath stages they must not be allowed to become very dry, as the roots are always more or less active, and should have sufficient water to keep the soil moderately moist. If they were not potted as soon as the foliage fell, which is the best time, the whole of the soil above the bulbs should be carefully removed as far down as can be done without disturbing the roots, and some good fresh loam and about a third of leaf soil with a sprinkling of sand supplied instead, giving as much water only as is needed to render the soil moist.

**PELARGONIUMS.**—Plants of Show and Fancy varieties that have rooted freely will now require a shift into larger pots, but by no means overpot them, which is too frequently the case, and causes them to produce more foliage than flowers. An 8-inch pot is the largest size employed for exhibition specimens; therefore a 6-inch pot is large enough for all ordinary decorative plants. A compost of good yellow loam, silver sand, and decayed hotbed manure is suitable for them, and they should be potted firmly. With the outside shoots pegged down to the soil, plenty of light, and a minimum temperature of 45°, good healthy plants will be procured.

**PRIMULAS.**—Keep these plants near the glass, and be careful in watering, giving when necessary a thorough supply, alternating with liquid manure. To insure the trusses coming up well above the foliage afford a temperature of 45° to 50°, ventilating upon every favourable opportunity. Some of the hardy kinds introduced to this structure from frames are welcome in spring. *P. cortusoides* and vars.; *P. nivalis*, *P. denticulata*, *P. intermedia*, *P. purpurea*, and *P. verticillata* are useful employed in that way.

Seed of *Primula sinensis* should now be sown; a frame on a hotbed or the shelf of a stove is a suitable position for them. There are now several good strains in cultivation, and it would be wise to procure those advertised by some respectable firm, as it is quite

as easy to grow a good variety as a bad one. Be very careful in watering the young seedlings.

**HARDY FLOWERS.**—All plants, especially young plants, in beds and borders, must have attention immediately the ground becomes fairly dry. Such plants as Pansies, Pinks, Carnations, young Phloxes, Pyrethrums, &c., are sure to be more or less displaced with the frost, and it is important that the soil be pressed gently yet firmly round them; or should dry weather ensue, as it will do before the flowering period arrives, the plants will sustain considerable injury. After the soil is firmed round the plants a surfacing of fresh compost will in many cases be advantageous, and if this is of a sharp gritty nature it will sensibly impede the movements of snails and slugs.—**FLORIST.**

THE FROST departed in the metropolitan district as suddenly as it came. "Every day," Mr. G. J. Symons writes to us, "from the 12th to the 27th of January the temperature was below freezing. It was one of the most remarkable cold periods of this century, but shorter in duration than that of January, 1814." Last winter the duration of the severe frost was from November 14th to December 28th, 1879; and the lowest reading of the thermometer at Blackadder, N.B., was 23° below zero, registered by a thermometer that Dr. Stuart considered quite correct; this year the greatest cold at the same place was 22° below zero. In Ireland the frost has been more severe this year than it was in 1879, and has been generally more intense in Scotland. At Chiswick in 1879 the lowest reading of the thermometer was 10°, or 22° below freezing; this year it was 5°, or 27° below that point. The average minimum temperature at Camden Square, London, during the frost of last winter was 27.7; this winter it was 18.8. The greatest cold at the same place was 16.1° on December 7th, 1879, and 11.8° on January 17th this year. The temperature of the soil at 1 foot below the surface on the last day of the frost this year was 33.1, and exactly the same on the last day of the frost of last winter. In reference to the weight of snow that fell in the metropolitan area chiefly on the 25th ult. and which, according to parliamentary reports, was estimated at 8½ million tons, the *Gardeners' Chronicle* suggests that the amount was probably a misprint for 3¼ millions of tons; and we quite agree with our contemporary, as, calculating on the acknowledged data that 12 inches of snow is equivalent to 1 inch of rain, and that an inch of rain equals 101 tons of water per acre, the result would be about as stated by the last-mentioned figures. We have heard of much injury resulting from the frost, but hope to learn that the snow has proved a valuable preserver of vegetation, and that the damage will not generally be so great as after last winter. As showing the inaccuracy of computing the "degrees of frost" instead of the readings of the thermometer, a correspondent informed us that there were "seven degrees of thaw" last Friday morning, meaning that the temperature was 39°.

— WE may remind our readers that the ANNUAL GENERAL MEETING OF THE ROYAL HORTICULTURAL SOCIETY will take place on Tuesday next, the 8th inst., at 3 P.M., when the report of the Council will be submitted, and the general business of electing officers and members of the Council transacted.

— AT the LINNEAN SOCIETY to-night (Thursday) the following papers will be read—"Notes on Cyperaceæ," by G. Bentham; "Observations on some British Fishes," by Dr. Francis Day; and "Remarks on the Coffee-leaf Disease in India," by William Biddie.

— WE are sorry to record the death on the 23rd ult. of MR.

P. J. PERRY of the old-established nursery at Banbury. Mr. Perry was second son of the late Mr. Thomas Perry, his predecessor in the business, and younger brother of Mr. Thomas Perry, who was formerly of the firm of Knight & Perry at Chelsea.

— WE learn that MR. DANIEL JUDD, who has been for some time gardener at Warwick Castle, recently retired from that post, and was presented by some friends in the neighbourhood with a handsome timepiece and gold scarf pin as a testimony of their respect. MR. W. IGGULDEN on resigning charge of the gardens at Orsett Hall was also presented by his neighbours with a handsome testimonial of their esteem, as by his courteous demeanour he had secured the respect of a wide circle of friends in the district.

— MR. J. PERKINS, Thornham Hall, Eye, Suffolk, sends us a RECORD OF THE FROSTS during the past four months, in which we notice that the lowest temperatures in each month were the following:—October 24th, 7° below freezing; November 23rd, 12° below freezing; December 22nd, 9° below freezing, and January 30° below freezing, or 2° above zero. In referring to the vegetable crops he observes that the Broccoli were all laid down in the autumn, and are saved; Lettuce, &c., which were covered with snow, were also uninjured.

— A VERY extensive cultivator of bulbs sends us the following note on the BLUE ROMAN HYACINTH—"This note is to warn those who, like myself, might be tempted to give it a trial, knowing the worth of the white Roman form. It is rightly named, but useless and not worth growing. After two seasons' trial I strongly condemn it. It is not in the least adapted for forcing, and a great per-centage of bulbs will not flower. It is no earlier than *Scilla siberica*, and cannot in any respect equal that charming little bulb."

— WE are requested to publish the following announcement:—"Messrs. James Carter & Co., having received the ROYAL COMMAND to attend at Marlborough House, that firm enjoys the high distinction of a royal warrant appointing them seedsmen and nurserymen to His Royal Highness the Prince of Wales."

— WE are informed that the ALEXANDRA PALACE AND PARK, Muswell Hill, will be sold by auction on February the 11th, by order of the London Financial Association.

— JUST on the eve of going to press we have received a lengthy report of the first ORDINARY GENERAL MEETING OF THE GENERAL HORTICULTURAL COMPANY that was held at Warwick House, Regent Street, on Monday last, which it is impossible under the circumstances that we can insert. The auditor's report shows that the amount of business done during the eight months was £22,600 2s. 8d., and the gross profit £13,919 16s. 10d. The profit and loss account shows a nett profit of £3,601 4s. 9d. Mr. Wills commenced business ten years ago with a sum of £300; on the formation of the Company the amount due to him was £24,581, £11,000 of which he took in fully paid up shares; he has since taken £10,000 in the same manner, so that his shares amount to £21,000. At the meeting Mr. Wills stated his willingness to relinquish the interest of his unpaid purchase money in order that the shareholders might receive a dividend of 5 per cent.; but the shareholders present, while thanking Mr. Wills for his liberal offer, declined to take from him what was lawfully his own. Much confidence was expressed in the position of the Society, and an increased number of shareholders is anticipated. The total number of shares taken is 2,414, the working capital having been only £7,906, and a good dividend is expected at the close of the financial year.

— THE Council of the Society of Arts inform us that they are prepared to award a Society's silver medal, together with

a prize of £5, which has been placed at their disposal for the purpose by Mr. G. F. Wilson, F.R.S., for the BEST LABEL FOR PLANTS. The object of the offer is to obtain a label which may be cheap and durable, and may show legibly whatever is written or printed thereon; the label must be suitable for plants in open border. These considerations will principally govern the award. The award will be made on the recommendation of a Committee, which will be appointed for the purpose by the Council. Specimen labels, bearing a number or motto, and accompanied by a sealed envelope containing the name of the sender, must be sent in to the Secretary of the Society not later than the 1st May, 1881. The Council reserve to themselves the right of withholding the medal and prize offered if, in the opinion of the Judges, none of the specimens sent in are deserving. Communications on the subject should be addressed to Mr. H. Trueman Wood, Secretary, John Street, Adelphi, London.

— THE RICHMOND HORTICULTURAL SOCIETY.—Last year was an especially trying one to not a few horticultural associations, both metropolitan and provincial, on account of the inclemency of the weather, and the rain falling on so many "show days." This necessarily affected, in some instances seriously, the finances of the societies, as the majority of them are to a very great extent dependant on "gate money" for their success. The Society under notice, we perceive, continues its prosperous course. Its income last year was larger than ever—£734 4s. 4d.; as also was the amount disbursed in prize money at the summer and autumn exhibitions—£315 3s. 6d., leaving a balance of £65 8s., the clear balance at the commencement of the year having been £10 4s. 4d. The two Shows held in 1880 were of remarkable excellence, certainly amongst the finest in the neighbourhood of the metropolis; they were, in fact, worthy of the Royal and distinguished patronage they received, and of the sound generalship and admirable management that have in seven years placed the Society in such a satisfactory position. A gratifying feature to be noticed is the great number of donors of special prizes, a circumstance that indicates the personal interest that is manifested in the Society, and which contributes materially to the vitality of all organisations of this nature. With the increasing support that may be expected to be accorded still greater results may be anticipated, the horticulture of a beautiful district will be improved, and much more than local fame achieved by this Society, to the success of which the untiring efforts of the Secretary, Mr. Chancellor, have so largely contributed.

#### SCIENCE IN HORTICULTURE.

I HAVE no intention of answering "SINGLE-HANDED," who has much misunderstood me, but wish to correct a statement. I did not say that the Sarracenias were dead, but that the pitchers which contained the flies were. Anyone who knows Mr. Bull's success as a grower would smile at the idea of his losing his plants through ignorance. I do not scoff at science, but at much which goes under its name. I have the pleasure of recollecting that I founded a Society for purely scientific purposes, which has done a good work; but in these days the true principles of inductive philosophy are pushed out of the way by "probabilities," "likelihood," and such-like uncertain things.—D., Deal.

I AM glad that "SINGLE-HANDED" did not include all clergymen among those from whom he expects to hear the same opinions with regard to science as he attributes to "D., Deal." Those who know anything of the subject are familiar with the names of Buckland, Sedgwick, and Conybeare, who in the early days of geology did so much to advance that science. All of these were clergymen; so was John Ray, the founder of modern botanical science, which can claim so many clergymen as its votaries. Then there was Bishop Stanley of Norwich; and we have still among us the Rev. M. J. Berkeley, who is an embodiment of all the sciences. From a pretty extensive knowledge of the clergy, my experience is that among those of them who are well educated there is a strong sympathy with science; but no doubt there are

among them some who have no taste for scientific pursuits, and others who have a hazy idea about what is science and what is not—in this respect ranking with not a few gardeners.

After all, however, "D., Deal," has done good service by contributing his letter on page 24, for it has called forth two interesting replies. Facts prove in a very conclusive manner that science has done very little towards averting the Potato disease; but we must all respect the efforts of those who by their researches and experiments have endeavoured to mitigate the effects of it. My object, however, is not to discuss the general question that has been so ably handled, but to advert to the subsidiary one of glazed flower pots, and to observe that your correspondent, "SINGLE-HANDED," who defends science so stoutly, gives it small credit in this matter. "Science," says your correspondent, "has proved for us that the only difference between ordinary pots and glazed ones is that ordinary pots get very dirty in a short time, while the glazed pots remain clean." If that is all that science teaches on this subject it is not much, although I agree it is important; but when "SINGLE-HANDED" asserts it is the "only difference," I must join issue with him. If I mistake not, science teaches something else on this question. But I must pause, for I am reminded that science is a two-edged sword, and cuts both ways, for I am informed that porous pots are scientifically sound in principle; and if I make the counter-assertion that glazed pots are also scientifically correct, and prove my assertion, and if "D., Deal," has proved they are correct also, what wonder is it that he alluded to them in the manner he did? I have not a doubt that he had good reason for his statement in respect of those pots, and I fail to see that he has written anything extraordinary regarding them, and certainly nothing so strange as the statement of "SINGLE-HANDED'S" "only" difference theory.

Science teaches me that glazed pots are essentially conservators of the virtues of the soil. If "SINGLE-HANDED" will analyse the water that passes through the rich soil of his flower pots daily I think he will find that it has not left *all* its manurial properties behind it. But he may naturally ask, "Is the water that passes through the soil in glazed pots different from that which passes through the soil of porous pots?" My answer is "No;" but there is another element in the case, and an important one. In brewing the oftener water passes through the malt the weaker the ale, and after three or four "mashes" it becomes very "small beer" indeed. So in water passing through the soil; it may be so frequent in light potting, and so necessary to be often applied with porous pots, that a great part of the soil's virtues are washed away quite out of reach of the roots of the plants. The oftener the soil is "mashed" the weaker it becomes in nutritive elements; and if "SINGLE-HANDED" will pot say a dozen Auriculas, which were the plants that "D., Deal," referred to, in glazed pots, and a similar number of the same vigour in porous pots, employing the same kind of soil in both instances, and will grow all the plants in the same house or frame, and count the number of times he waters each dozen for six months, commencing with March, I think he will find a striking difference. The plants in the glazed pots will not, if properly managed, require watering half so many times as those in porous pots, and the soil in the former will consequently be found, if analysed at the end of the summer, much more fertile than the much-watered soil in the porous pots. I know a large collection of plants that are grown in glazed pots for the reason stated, and I should not hesitate placing these in competition as examples of healthfulness against any collection of plants of the same kind in the kingdom. I think, therefore, for the reason stated, that "SINGLE-HANDED'S" "only" difference theory is not a great compliment to science that he defends so bravely.

There is a certain florist in the south of England named Henry Cannell. Now this florist is not professedly a scientific man, but he acts on scientific principles nevertheless when he catches the water that drains through his flower pots into tanks below them and uses it over again. When in London three years ago I called at Swanley, and had the pleasure of half an hour's conversation with Mr. Cannell. He showed me his system of roof-heating—that is, of conveying small hot-water pipes along the roofs of his houses to "dissipate damp" from his Pelargoniums; he told me, too, of his tanks. "Depend upon it," said he, "there is no water like this" (the water that had drained from his plants), there isn't indeed; it's just the right strength, and the plants like it. Look at them!" I did look at them, and fine they were. They were not in glazed pots, but their condition was confirmatory in a very striking and practical manner of what I have advanced, and I feel I am justified in disputing the theory of your excellent correspondent that the clean and dirty pot question is not the "only" thing that science teaches on glazed pots.

Mr. Cannell, I trust, will pardon me for mentioning his name in connection with this subject; but I may say that I was so much pleased with his place and the attention I received—or more properly the information I obtained—that on the very first opportunity I shall visit the “Home of Flowers” again, but I do not promise that I shall tell the genial owner that I am—  
A NORTHERN GARDENER.

#### TINNEA ÆTHIOPICA.

ONE of the most charming plants for flowering in stoves at this period of the year is *Tinneæ æthiopica*, and in many gardens where it has received the little attention needed to have it in satisfactory condition it has become almost indispensable. Not only is the plant elegant in habit and the flowers richly and distinctly coloured, but they also possess a delicious fragrance very strongly suggestive of Violets, so that a few specimens in bloom will agreeably perfume a moderately large house. When, in addition to these qualities, the season of its flowering is considered, further recommendation is needless, and all gardeners

Fig. 21.—*Tinneæ æthiopica*.

who have to maintain a stove in an attractive condition will readily appreciate the usefulness of the plant, especially those who have grown it.

The woodcut (fig. 21) faithfully represents a small spray of a specimen, and also fairly shows the form, position, and numbers of the flowers. The corolla is two-lipped, the lower lip being of a fine maroon colour, and the upper one more of a rich crimson hue. The calyx is large, slightly inflated, and pale green. The flowers are freely produced in axillary clusters at the upper portion of the shoots. The culture is easy, a stove temperature being required, and a light rich soil of loam, leaf soil, and sand, the pots being carefully drained. Cuttings of the young shoots strike readily under a bellglass in a little bottom heat.

The plant has been found by Dr. Kirk, Capt. Grant, and Mdle. Tinné in tropical Africa, but to the latter is due the honour of having introduced it to this country. Seeds were sent to England in 1865, and from these plants were raised, one of which was first

exhibited at the London International Horticultural Exhibition in 1866 by J. A. Tinné, Esq., Briarley, Aigburth, Liverpool.—L.

#### THE VICTORIA AND PARADISE NURSERIES.

WHILE the great metropolis was still comparatively silent under its heavy and unusual covering of snow, with a temperature considerably below freezing point, but a clear atmosphere brightened by the somewhat feeble rays of a January sun, I visited Mr. B. S. Williams' large collections of plants at Holloway. There was snow in abundance, of that peculiar shade which it assumes after exposure to London smoke for a day or two, and all the cooler houses were surrounded by thick fringe of icicles suspended from the eaves, in many cases exceeding a yard in length. Mats had been freely called into requisition to aid the stokers in maintaining the necessary heat for the numerous choice plants from tropical regions, so that there was little in the outside appearance of the houses to convey any idea to a stranger of the floral beauties within. But I was confident there would be ample to compensate me for my journey, an expectation that was fully realised, though of course January is not the best time to visit a London nursery. For the benefit of those readers of the Journal who, being unable to visit our great metropolitan nurseries, are content with gaining their information second-hand, I will briefly note a few of the plants that attracted my attention, and which are worth the attention of gardeners or amateurs. The great feature in the Victoria Nurseries is at all times the Orchids, and with them therefore I will commence.

ORCHIDS.—All these appeared in excellent health; many were flowering, including several really useful species and varieties, the fresh vigorous growth and dark green foliage in other cases almost compensating for the absence of flowers. One of the first I observed was a specimen of the pretty *Dendrobium luteolum* with a number of its distinct pale yellow or buff-coloured flowers, which at this season are particularly acceptable. Another useful winter-flowering species of the same genus is *D. heterocarpum*, which with the floriferous *D. moniliforme* was in good condition. *Lælia anceps*, recently mentioned in this Journal, was represented by several beautiful varieties; one, appropriately named *grandiflora*, having unusually large blooms and a richly coloured lip. *Lælia albida*, a species with small whitish flowers, is not very striking, but well worth growing. Among *Cattleyas* the most notable were some handsome forms of *C. Trianae*, one named *rubra* possessing great depth of colour, and another—*magnifica*, combining clearness of tint with fine size and substance of blooms. A distinct form of the beautiful hybrid *C. exoniensis* was flowering well, and *C. chocoensis*, with a rich purplish lip and white-fringed sepals and petals, was similarly notable. An imposing and attractive Orchid that is too seldom seen is *Angræcum eburneum*; and the variety *superbum* as grown at Holloway is still more valuable, as it surpasses the type in the size and purity of the white lip. *Angræcum sesquipedale* is almost too well known to need comment, but a large and remarkably vigorous specimen formed a very conspicuous object in a bank of Orchids owing to the size of the flowers and the great length of the spurs. The *Vandas* were looking uncommonly well, and Mr. Burton informs me that they have considerably improved since the hexagon shading material has been substituted for that of heavier texture on the house containing them, as they have thereby been exposed to more light without the danger of scorching the foliage. Good forms of *V. tricolor*, *V. insignis*, and *V. suavis* were in flower, and the characters of those species are so well known that it is unnecessary to further refer to them. The generally appreciated *Zygopetalum Mackaili* well deserves all that has been written in its favour, for it is the most useful of the genus both in respect to its easy culture, its free flowering, and the beauty of its blooms. It was strongly represented by specimens that had been in flower for a considerable time. *Pilumna fragrans* with its charmingly scented flowers and the striking *Phaius grandifolius* are very dissimilar in appearance, but they are equally noteworthy, the latter being so free of growth and bearing its tall vigorous spikes of blooms in the dull season.

Among Orchids requiring a cooler temperature than most of the above the *Masdevallias* and *Odontoglossums* are grown in large numbers, but at the time of my visit there were not many in flower. *Masdevallia tovarensis* was, however, bearing its pure white blooms, and the peculiar little *M. polysticta* was also represented. The first mentioned is unquestionably an acquisition, as it flowers readily in a young state, and produces such a number of blooms that when associated with some of the richly coloured forms are most pleasing. *Odontoglossum cirrhosum* was in first-rate order, but the handsome variety of that species named *Klabochorum*, with its large blooms spotted with rich crimson

maroon, was especially remarkable, as it is highly valued by most Orchid growers. *O. Alexandræ* is a general favourite, and one specimen had a spike of nearly twenty fine flowers—an admirable example of an elegant species. Mr. Williams' specimens of *Cypripedium villosum* are well known, and though I missed some of the largest, there were still grand pieces in superb condition which were fast advancing for blooming.

In another warmer department were those charmingly delicate Orchids—*Phalenopses*, which can perhaps scarcely be rivalled in the whole of the immense order. The majestic *P. Schillerana* and the beautiful *P. amabilis* and *P. Lowii* were blooming with a small-flowered but pretty species named *P. Mannii*, which is rarely

seen. It produces a small raceme of several flowers with narrow petals and sepals, yellow spotted with chocolate, which renders it very distinct from the other species, and a casual observer might take the flowers to be those of an *Odontoglossum*, some of which they resemble. There were many other Orchids blooming in the various houses devoted to them, but the few noted will suffice to show that there was no lack of attractions notwithstanding the unfavourable exterior condition.

STOVES.—A cursory view can only be given of the occupants of these structures, although they merit a detailed description. Crotons were richly coloured, all the best varieties being grown; but the two new forms, *C. Stewartii* and *C. Warreni*, were con-

Fig. 22.—*IMANTOPHYLLUM CONCINNUM* (HORT. WILLIAMS).

spicuous for the elegance of their habit and the bright tints of the foliage; they are both first-rate varieties. *Dracænas* were similarly notable; the graceful narrow-leaved *D. superba*, so well adapted for decorative purposes, being excellent, with its bright crimson-streaked foliage. *Nepenthes* it is well known constitute one of the specialities at Holloway, and so many beautiful hybrids, species, and varieties are included in the collection that it is not easy to select the best; however, one that particularly attracted my attention was *N. Hookeri maculata*, which has very large pitchers thickly spotted with crimson maroon. In a less humid and cooler department were the two useful plants *Toxicophlæa Thunbergi* and *spectabilis*, which produce their white fragrant flowers in dense axillary clusters, even small plants in 60 and 48-size pots having clusters at nearly every axil. This is one of the good qualities of the plants, and as they are easily grown they are welcome additions to any collection either in a stove or intermediate house.

Near the above were plants of the peculiar but pretty *Cochlostema Jacobianum* which were fast advancing for flowering; it is surprising what fine specimens can be obtained from seed in about two years from the time of sowing with very ordinary care. A Bromeliaceous plant that is seldom seen in England is *Pepinia aphelandræflora*, which has long narrow strap-shaped leaves and spikes of crimson flowers; the habit is compact and the growth free, and it is likely to prove useful for associating with other bolder plants on the shelves of a stove. *Alpinia albo-lineata*, the new variegated form in this well-known Zingiberaceous genus, is distinct and neat, the narrow leaves being green striped with white; it retains the variegation very well as it advances in growth. I had nearly omitted mentioning the *Anætochili*, *Goodyerias*, and similar plants which would perhaps have been more correctly noted under the Orchids, but they seem more popularly to come under the heading of fine-foliage stove plants. The collec-

tion is very large, and the species and varieties in those genera are thoroughly well grown in the nurseries under notice; and many gardeners who imagine the difficulties attending the culture of those plants are so great, would be surprised to see the freedom with which they grow when a little skill is exercised in providing the particular temperature and humidity needed. In leaving one of these departments I observed a remarkably handsome specimen of *Eucharis grandiflora* with broad deep green leaves, and about thirty scapes, each bearing several large flowers—an admirable example of culture, and proving what can be obtained by careful treatment even within reach of the London smoke.

**GREENHOUSES.**—The display of flowers was not very extensive in these houses, for it is somewhat early in the season, but judging from the healthy appearance of Heaths, New Holland plants, and others to which departments are specially devoted, there is every promise of satisfactory flowering at a later period. Though it is generally believed that the demand for hardwooded plants is greatly diminished, this is not the case to such an extent as imagined, for large numbers are yearly propagated to maintain the supply. Yet there are many beautiful plants now comparatively scarce which might well be recalled to public notice, and if especial skill is requisite in their culture they are, when well attended, more creditable to the grower than are the majority of soft-wooded plants. In the Camellia house there was a grand show of buds, the handsome rich green clean foliage indicating the health of the plants and the prospects of good and abundant flowers. A few were already expanded, among them being the old but useful and floriferous variety *Donckelaarii* with its large crimson and white mottled blooms. Another neat double-flowered variety very profuse and of good habit was *David Boschi*, the blooms of moderate size and rosy pink in colour. *Madame Ambroise Verschaffelt* with white blooms marked with reddish crimson was a noteworthy variety; but *Comtesse Mastiana* was particularly fine, with beautiful foliage, of good habit, and bearing white symmetrical flowers slightly streaked with pinkish crimson.

One other plant I wish to note. This is a new *Imantophyllum*, received by Mr. B. S. Williams from the Cape of Good Hope, whence it was forwarded by one of his collectors a few years ago. It was considered distinct, and was appropriately named *Imantophyllum concinnum*. The plant was growing in a warm house, but I suppose it is amenable to the same treatment as its congeners, with any of the small-flowered forms of which it can be favourably compared. It is quite in the way of *I. cyrthanthiflorum*, but is superior to it in the colour of the flowers, which is much brighter, something of an orange-scarlet tint. The engraving (fig. 22) was prepared from the specimen referred to above, and represents a scape from a plant in extremely good condition. The small figure indicates the habit. It is unquestionably an elegant plant, and one that should be grown by all who admire the genus in which it is included. The figure now given is, I believe, the first published.—L. CASTLE.

#### KITCHEN GARDEN.

WHERE outdoor operations are still stopped by the weather attention should be given to such work as making labels of various sizes, also the pointing of Pea sticks, stakes for Runner Beans, &c., so as to save time later on. When the weather becomes favourable make a small sowing of Early Munich Turnip upon a warm south border, also Early Nantes Carrot in a similar position, giving a good dressing of soot before sowing, and point it in. A sowing of Radishes should be made on a border at the base of a south wall, also a small sowing of some early variety of Cabbage Lettuce, such as Early Paris Market, and White Naples or Queen Onion in a similar position. When the weather is favourable take up Jerusalem Artichokes, placing those required for use in damp sand, and make fresh plantations in good soil and an open situation, planting 12 to 15 inches asunder in rows 24 to 30 inches apart. When Seakale is taken up regularly for forcing a plantation of the smaller roots or crowns may now be made in rows 18 inches apart; and if necessary make fresh plantations of Rhubarb, which to be good should be replanted every third year in ground

deeply trenched and heavily manured, selecting strong crowns from the older roots.

**Forcing Department.**—Sow Celery in pans for early use, placing them in gentle heat, and when the plants appear keep them near the glass. Sandringham White and Leicester Red are suitable varieties. Make a sowing on a hotbed of Brussels Sprouts, Early London and Walcheren Cauliflower, and if necessary of early varieties of Cabbage. Where a bed of fermenting materials has been prepared place a frame over it and sow Cabbage and Cos Lettuce, ventilating freely after the plants appear. A good supply of fermenting leaves and dung, three parts of the former to one of the latter, should be prepared for lining hotbeds on which Radishes, Carrots, and Potatoes are growing, also to make up fresh beds for like purposes as required. Sets of Potatoes should be placed in boxes and covered with leaf soil, an early Peach house or vinery being suitable to start them into growth; and when the shoots are a couple of inches long plant on beds prepared to receive them, the soil having been previously warmed. Introduce fresh roots of Rhubarb and Seakale to the Mushroom house to maintain the succession.

#### FRUIT HOUSES.

**Peaches and Nectarines.**—When the fruit is all set in the earliest house syringing the trees must not be neglected in favourable weather to prevent insects increasing. Where the fruit is too thickly set a few of the smallest may be rubbed off, especially those at the back of the trellis. Disbudding the young shoots will need attention, but proceed cautiously, taking only a few of the strongest foreright shoots at a time, retaining a growth as near the base of the current bearing shoots as possible, and another above, or at least level with the fruit, to draw the sap to it. Fumigate carefully upon the first appearance of aphides. Allow a night temperature of 55° to 60°, 60° to 65° by day, with an advance from sun heat to 70° or 75°. Early Peach houses in frosty weather require careful attention, cold draughts giving a check to the foliage and young fruit. On clear sunny frosty days it is better to allow the temperature to rise a little than to ventilate excessively to reduce it. For inside borders some weak liquid manure will aid the fruit swelling in their first stage, but it must not be afforded trees that are too vigorous. Trees in the house started early last month are in full blossom; discontinue syringing, except to damp the borders and pathways once or twice a day, according to the weather, until the fruit is fairly set. If there be a superabundance of bloom thinning may be practised with advantage, removing blooms with two or three pistils, and those at the back or under side of the shoots, retaining the most vigorous and best placed. Continue 50° as the night temperature, 55° by day, ventilating above that degree, and allow an advance from sun heat to 65°. Leave the ventilators slightly open all night. Fertilise the blossoms every day when the pollen is in a fit state, either with a camel's-hair pencil or other suitable means. The house for affording ripe fruit about the middle of July may now be closed, damping the trees and paths in the morning and afternoon, the latter sufficiently early to have the trees fairly dry before night. In the day 50° is sufficient, advancing to 60° or 65° from sun heat with full ventilation, and 40° to 45° at night from fire heat. Continue the pruning, training, and dressing of the trees in late houses with as little delay as possible. Ventilate fully, except during frost, so as to retard the flowering, and see that there is no deficiency of moisture in the inside borders.

**Vines.**—Vines started last month will now be growing freely, and with fermenting materials in the house progress will now be rapid. Syringe the rods well three times a day until the bunches are formed, when it should be discontinued; but atmospheric moisture must be provided by frequently damping the walls and paths. Mulching is also beneficial, as the ammonia rising from it will assist the foliage and keep red spider in check. Ventilation will require great care, especially in frosty or cold windy weather. Keep the fires going every morning until a little air can be given, closing early, and allowing a rise of 5° to 10° on fine afternoons after closing. Houses where the Vines are flowering should be kept at a steady night temperature of 65°, with a rise to 70° or 75° by day, and an advance of 5° to 10° after closing. Assist fertilisation by drawing the points of the bunches to the light, shaking the Vines every day,

or dust ripe pollen over the pistils. A constant circulation of dry warm air at this stage is very beneficial. Attend to stopping, tying, and thinning in the early house. Keep up a supply of ammonia by the addition of a few fresh horse droppings, and see that inside borders are well supplied with weak tepid liquid manure. Vines in pots should never be allowed to become dry, supplying them with liquid manure if needed. Vine eyes may now be inserted in pots, pans, or squares of turf. Ripened wood only is suitable, filling the pots with friable compost, inserting the buds with a pinch of sand about half an inch beneath the surface, and plunge in a bottom heat of 80°.

#### PLANT HOUSES.

*Orchids.*—A rise of 5° in the temperature may now be given, the East Indian house being kept at 70° by day, allowing 5° more from sun heat, the night temperature being 5° to 10° lower than by day. The moisture must be proportionate to the increased temperature, admitting air in favourable weather, and so that it will become warmed before it reaches the plants, as cold currents coming in contact with the plants are very injurious. The potting of *Aërides*, *Camarotis*, *Saccolabiums*, and *Vandas* may now be proceeded with. Do not supply water for a few days prior to potting, as the old material is more easily removed from the roots than when wet. Plants that do not require shifting should have as much of the old material taken from the roots as possible and fresh supplied. The chief point in potting is to drain well. Baskets must be examined, and if any show signs of decay transfer the plants to new ones. Many *Burlingtonias*, *Dendrobiums*, *Sophranites*, &c., succeed best on blocks of wood, a little moss being placed on the blocks, and the plants fastened on with copper wire and copper tacks. The blocks must be damped thoroughly twice a day at this time of year. *Stanhopeas* that have become dry should be dipped in a tub of tepid water, so that the whole may be thoroughly moistened. *Cattleya Aclandiae*, *C. marginata*, and *C. Regnelli* should be repotted as soon as they show signs of starting into growth. They should be suspended from the roof where they can obtain a good circulation of air and have plenty of light. *Miltonias* succeed best in perforated pans suspended from the roof in the Mexican house where they can conveniently be shaded. For potting, which should be attended to when starting into growth, employ good fibrous peat with a little sphagnum.

## THE BEE-KEEPER.

### ABOUT HIVES, WHICH ARE THE BEST FOR PROFIT?

"THE battle of the hives" seems to be renewed again, to judge from the various deliverances on the subject which bee-keepers at home and abroad have recently made. Last October at a conversazione of the British Bee-keepers' Association held in the Agricultural Hall, Islington, an interesting paper was read by the Rev. E. Bartrum, M.A., Head Master of the Grammar School, Great Berkhamstead, on the Stewarton hive. After detailing cases of remarkable harvests of honey obtained in one season from these hives, reaching, in the case of a Scotch clergyman, the astonishing quantity of "445 lbs. of the parent comb," he remarks that "a hive which has secured such remarkable results must have features connected with it of unusual merit." These he proceeds to detail in order. In his opinion we find three special advantages dilated on, which I may sum up as follows:—

1, The remarkable power of expansion and contraction of these hives, and consequently the ready prevention of swarming, if this be deemed desirable.

2, The time and trouble spared in the management of this hive in comparison with other hives, making it notably the busy man's hive. In this respect Mr. Bartrum thinks it compares most favourably with the ordinary bar-framed hive.

3, The Stewarton hive winters well if only ordinary and proper care be taken.

The two particulars first mentioned alone deserve attention, because any and every hive will winter well "if only ordinary and proper care be taken." Passing over this last, I may observe that the only speciality of the Stewarton hive which seems to be

an advantage over other hives, is that a busy man may find it suit him better than another sort of hive. As for the first alleged superiority of the Stewarton, it is more than matched by the power of expansion and contraction now provided in improved bar-framed hives. This appears to have been the general sense of the meeting when Mr. Bartrum's paper came to be criticised in the discussion which followed. As for the old objections to the workability of the Stewarton, which have always deterred me from using them, they remain in full force, and they detract not a little from the benefit of the hive even to a busy man. Mr. Bartrum very fairly puts some of these objections forward. They include the difficulty of moving or removing the slides, and much time and trouble must be bestowed upon these. Another formidable objection is the unsaleableness of the large supers, and then there is the costliness of the Stewarton in its completeness to be further taken into consideration. Mr. Cowan further objected to the screws which have to be removed before an examination of the frames can be made, an operation which has to be gone through in each body-box—no easy matter when a hive is full of bees; and Mr. Cheshire pointed out the difficulty of overhauling a Stewarton to find the queen, which was often impossible.

The weakness of the whole argument in favour of the Stewarton on this occasion appears to lie in the fact of its being compared with the "ordinary" bar-framed hive. But why this? The Stewarton, being confessedly the best hive of its kind, should be compared with the best of the bar-framed hives to make the comparison of any practical value. If, indeed, the Stewarton hive could be made generally to yield honey harvests like that mentioned in the case of the Scotch clergyman before alluded to we should at once bow to its superior merit. Nobody, however, doubts that this was a very exceptional case, and that it is to be explained by something as exceptional in the management of this particular stock, or in the condition of the bees themselves, or their queen; nor can there be any reasonable doubt but that a superior bar-framed hive under like favourable circumstances would have yielded a harvest as great if not greater. See, too, how doctors differ! At the same time and place Mr. White stated that, "contrary to the experience of Mr. Bartrum, he wished to give up his Stewartons, because he found they took up too much time and gave him too much trouble!"

Leaving, then, the Stewarton hive to fight its own battle—or shall I say, to maintain its ground as best it may?—I will proceed to contribute towards the still further improved use of the bar-framed hive a few suggestions which have occurred to me as the result of my experience this last summer in its management. In his remarks upon the superiority of the bar-framed hive in course of the discussion already referred to, Mr. Cheshire put his finger upon one of its weakest points, I mean in the ordinary use of the bar-framed hive, without opportunity for its expansion or contraction. But it is not only true that "a principal desideratum in any form of hive lies in its expansibility and contractibility." Something is wanted in our method of using this improved capability of the hive. What that is, is suggested by him where he says that "the great secret of success is to increase the brood nest gradually, and to obtain a large quantity of bees before the beginning of the honey harvest." Now a large quantity of bees can be obtained in a large bar-framed hive without the gradual increase of the brood nest. We have proved this abundantly here. Where I see a principal advantage in these improved bar-framed hives is in the facility afforded for contraction of the brood nest at the proper time far more than in its extension. Hitherto this has been supposed to be limited to autumn use in order to prepare the bees for comfortable wintering. True, Mr. Cheshire is aware of the advantage I speak of, and he notices it too in the same discussion where he says, "Give the queen room enough; but short of this, all hives should be contracted as much as possible when supers are put on—that is to say, when the yield of honey is at its height." So far so good. But I am not sure that his following advice is not open to improvement. He adds that "all combs containing no brood should be removed." On the contrary my advice would be, Leave all such combs, but remove the brood combs, all save those which contain the largest quantity of brood in open cells and eggs, but this only at the crisis of the honey-gathering season.

What to do with the sealed brood combs I will speak of in a future paper. I must also reserve for another occasion my reasons for suggesting a different treatment to that recommended by Mr. Cheshire. I will content myself with saying here that my treatment of all the strongest hives in our apiaries, so far as it is diverse from his, aims at stopping altogether the queen's functions in the hive, and compelling the bees to devote their whole attention to honey-gathering. This can be done in several ways, but I will deal first with that which Mr. Cheshire evidently

has in view—namely, the production of the largest quantity of honey in supers.—B. & W.

### PACKING BEES FOR LONG VOYAGES.

DO THEY NEED A DAMP ATMOSPHERE?

MR. M. H. MATTHEWS, in the *Journal* of January 20th, asks me to give some explanation of the utility of water as supplied to bees during their transit to New Zealand, and kindly adds some quotations from a journal of our antipodean colony, in reference to which, beside doing my best to answer his theory, I desire to make a remark or two, as the questions involved touch the whole economy of the hive more thoroughly than at first sight appears.

The device of wet sponge, by the assistance of which the bees were at length carried successfully to New Zealand, is not new, as the southern paper quoted states, which may be seen by referring to the *Journal of Horticulture* of June 3rd, where in an article entitled "Transporting Bees to India," I thus explained it—"During 1878 and 1879 I sent two stocks and two nuclei *via* the Red Sea to Bombay; the bees after their unshipment had a further journey into the interior, entailing an incarceration of nearly forty days before they reached their then owner, an Indian gentleman of distinction. The nuclei carried each, four of my half Woodbury frames, as used by me formerly for queen-raising. These were well stored with sugar, while the backs of the boxes contained pouches cut off from the bees by perforated zinc, and into these pouches sponges filled with water were occasionally put during the voyage. Perforated zinc covered the frames above, while the boxes were made 2 inches deeper than accommodation of the frame required. No other precautions were taken except that the combs were well fixed and the frames secured against lateral sway. Both nuclei arrived in capital condition."

The southern editor mistakes altogether the use of the sponge when he says, "it appears to have secured that cool and moist atmosphere necessary for bees." The water is really required for drinking. When honey is first gathered it is perfectly limpid, and then contains so much water that it is both food and drink, but after it has been some time stored the high temperature evaporates much of its fluid, and the inspissated mass is ready for sealing over. When bees are obtaining abundance of fresh nectar they do not require water, but it becomes a necessity if they are forced to feed on evaporated honey. During very cold weather, however, when they could not gather it, by a most interesting adaptation they do not need it; for their large quantities of honey are consumed to generate heat, and the carbon of the saccharine matter undergoes combustion, or more properly oxidation, the residue (consisting of hydrogen and oxygen) being freed in the form of water; so that actually the dry sugar of the honey becomes a water-former, while in addition the quantum of aqueous matter which even evaporated honey contains is put at the disposal of the bees. This will explain why some say bees need water, and others strongly assert the contrary.

I quite agree with Mr. Matthews that the New Zealanders have seen the advantages of Ligurians through a magnifying glass. That they are valuable bees we all are agreed, but after much painstaking comparison I do not believe that they raise grubs more uninterruptedly during the twelve months than do the blacks, although on the whole the former are without doubt more prolific than the latter. Bees will occasionally, if well cared for, breed here during the very severest weather. A few months since I gave an instance in the *Journal* of evidences of egg-laying and brood-raising being continued in most of my hives both by blacks and Ligurians on December 19th and 20th of 1879, most intensely bitter days. And further in their favour Ligurians are when pure very generally of mild temper, while their greater beauty increases the pleasure of possessing them, but they persistently cross, and so will I fear doom to disappointment the expressed hope that the yellow-banded will soon become as common as the black variety, unless indeed the yellow blood be kept up by continuous new importations. But though this hope may fail the crossing will greatly improve the stock, intensifying it in all directions, not excluding unhappily its disposition to sting. In a big apiary no doubt any special characteristic may be increased or decreased as desired, even in the absence of controlled fertilisation by continually raising queen cells from the eggs of that queen, stocks of which seem to present in a most marked degree the features we are seeking. I make it a rule to get rid of any queen whose progeny are disagreeably ferocious, notwithstanding the fact that they may be excellent in some other points.—FRANK R. CHESHIRE, *Avenue House, Acton, W.*

### TRADE CATALOGUES RECEIVED.

Kelway & Son, Langport, Somerset.—*Manual for 1881 (Illustrated).*

William Fell & Co., Hexham, Northumberland.—*Spring Seed List, 1881.*

The General Horticultural Company (John Wills), Limited.—*Catalogue of Flower and Vegetable Seeds, Fruit Trees, and Roses.*

John Cattell, Westerham, Kent.—*Catalogue of Flower and Vegetable Seeds.*

C. Pocock, Wincanton, Somerset.—*Catalogue of Flower and Vegetable Seeds.*

S. Dixon & Co., 34, Moorgate Street, and at Hackney.—*Catalogue of Flower and Vegetable Seeds.*

William Rumsey, Waltham Cross.—*Catalogue of Flower and Vegetable Seeds.*

Wm. Cutbush & Son.—*Catalogues of Flower and Vegetable Seeds, and Stove and Greenhouse Plants.*

John George Hill, Yeovil.—*Catalogue of Flower and Vegetable Seeds.*

Robert H. Poynter, Castle Gate, Taunton.—*Catalogue of Flower and Vegetable Seeds.*

J. T. Rofe, Cecil Road, New Town, Enfield.—*Catalogue of Flower and Vegetable Seeds.*

W. P. Laird & Sinclair, Dundee.—*Catalogue of Vegetable and Flower Seeds.*

Kerr & Fotheringham, Dumfries.—*General Catalogue.*

**Books (A Learner).**—The following would no doubt meet your requirements:—"The Greenhouse Manual," published at this office, price 9d., post free, 10d.; and Mr. B. S. Williams' two volumes on "Stove and Greenhouse Flowering and Fine-foliaged Plants," published at the Victoria and Paradise Nurseries, price 5s., or post free 5s. 5d. each. (E. S. R.).—We do not know of any book that will exactly meet your requirements; the best probably is Kemp's "How to Lay Out a Garden," published by Messrs. Bradbury Agnew, & Co., Bouverie Street, London.

**Liliums from Seed (Devonian).**—The time that elapses between the sowing of the seed and the flowering of the plants varies somewhat in different species, and is governed also to some extent by the mode of culture adopted. You do not state the species you are desirous of raising from seed; but we shall shortly publish a record of the experience of a cultivator who has raised and flowered plants of *L. auratum* from seed, and who has seedlings of some other species that are approaching the flowering stage.

**Climbers for Trellis (Reader).**—As you require annuals for covering the space quickly and temporarily, we think you can do better than send to a seedsman for packets of the best varieties of *Tropaeolum Lobbianum*, *T. peregrinum* (the Canary Creeper) would also be suitable, as would the varieties of *Convolvulus major*. The *Tropaeolums* you name are not annuals, and would not be likely to cover the space so quickly as you desire. The *Tacsonias* are readily raised from seed and grow quickly, but they do not flower freely except from cuttings, nor are they annuals; neither is *Eccremocarpus scaber*, which flowers from seed the first year if the plants are raised early. Such annuals as those just named would probably answer your purpose best, also Sweet Peas if the house is a light one.

**Bulbs Frozen (An Alarmed Contributor).**—You need be under no apprehension regarding the failure of your Hyacinth beds, even if the bulbs were only covered 3 inches deep in November. No doubt, as you suppose, the frost penetrated to a greater depth than that; still we are confident, if you examine the bulbs carefully, you will find them firm with healthy roots, and the crown growth fresh and satisfactory. Bulbs planted very late, and which do not emit roots before winter, are much more liable to injury than those that were established before the occurrence of severe weather by having been planted at the right time. You must not, however, dig up the bulbs to examine them. If you partially clear the soil from around one without in the slightest degree injuring its roots, we feel sure you will find it healthy, and you may take it as a type of the rest, and wait patiently for your "feast of flowers."

**Vines in Pots (A. Lawson).**—As the canes are no thicker than an "ordinary penny pencil," you had better cut them down at once to a good bud just above the surface of the soil, and insure a strong fruiting cane for another year. If you attempt forcing them now you will obtain no fruit from them either this year or next. Keep them cool for two or three weeks after cutting them down, then place them in a very light position in a house having a minimum temperature of 50°, increasing the heat as the growth advances, and shifting into larger pots when the shoots are a few inches in length, and securely affixed to stakes, watering the Vines very carefully after they have been repotted. They will then form strong canes early in the season, and be matured before late autumn, and be in good condition for bearing next year.

**Climbers in Boxes (H. F. Foy).**—The very strong growth made by your *Habrothamnus* and *Tacsonia* indicates that the roots may have passed through the bottom of the box into the soil below; in that case the plants cannot be removed without receiving a considerable check, but if all the roots are within the box we think you may divide the plants without hindering them from flowering this year. Assuming that there is some space between the two plants, we should cut the soil and roots with a sharp spade or other more suitable implement, and remove the plants with the squares of soil adhering to their roots, and place them in the desired positions. As they produce roots freely they would sooner recover from the check received by removal than they would were you to try and preserve all the roots of each plant by disentangling them and separating the soil from them, as you must do in the process. Water the plants sufficiently, yet judiciously, after removal, and syringe them occasionally if the weather is bright and warm. This advice is given on the assumption that the box is crowded with roots.

**Frosted Potatoes** (*Subscriber*).—If the tubers remain sound and firm they will no doubt grow, but if they have turned soft their vitality is destroyed. Any which you are doubtful about should be placed in leaf soil in a rather warm position, when they will soon show signs of growth if the frost has not destroyed them; they must, however, be kept perfectly cool so long as they remain in a frosted state, as the thaw cannot be too slow.

**Camellias** (*Hopewille*).—The Camellias you name may be briefly described as follows:—Martha, flower large, finely imbricated, and pure white; Principessa Clotilde, handsome flower banded with white and barred with red; Auguste Delfosse, very symmetrical blooms, bright reddish orange, few stripes; Marchioness of Exeter, a very beautiful variety, with soft peach-coloured blooms. Incarnata is, we think, a striped variety, and the other we do not know.

**Glass-Heating** (*C. B.*).—We are obliged by your letter. You do not, however, give the name of the firm who heated the house in the imperfect manner indicated. An estimate should be had for the erection of structures, and it can be accepted or not. As to the glass, unless the vendor delivered it himself you had in law no claim against him. If it was sent by rail, the railway company become the bailee, and you could have recovered damages from them, not from the consigner, who was not "answerable for breakages," even if he had made no such notification as that quoted; indeed in a case of this kind these words were quite superfluous, assuming that the goods were sent by rail or some other common carrier.

**Roses for Exhibition** (*J. B.*).—To obtain Rose blooms of exhibition quality earlier than the "general run" of the rest of the collection, much may be done by early pruning and growing them in a favoured position, but the following will be found more precocious than some others:—Madame Victor Verdier, Charles Lefebvre, Annie Laxton, Docteur Andry, Dupuy Jamain, Général Jacqueminot, Mdle. Engénie Verdier, Marquise de Castellane, Royal Standard, Sénateur Vaisse, Mdle. Marie Rady, and Lord Macaulay. Late bloomers are Star of Waltham, Emilie Hausberg, Baronne de Rothschild, Duc de Rohan, Duchesse de Vallombrosa, Madame Charles Wood, Madame Hippolyte Jamain, François Michelin, Reine du Midi, Sir Garnet Wolseley, Reynolds Hole, and Devienne Lamy. Such information as you need respecting the "classes for Cheshunt-raised Roses and similar classes," can only be obtained from the Secretaries of the National Rose Society. If you write to the Rev. H. H. D'Omhain, Westwell Vicarage, Ashford, Kent; or to Edward Mawley, Esq., Addiscombe Road, Croydon; either of them will send you a schedule of prizes when ready for distribution.

**Roman Villa at Brading** (*C. Waring*).—The discovery of the remains of this villa in the Isle of Wight has occasioned many inquiries, which are all answered in the following notes.—Statues of the tutelary deities were always placed at the garden gates which opened upon a parterre. The walks were edged with Box, or with a dwarf Conifer. The lawns had evergreen enclosures, and some of the evergreens were clipped into the shape of animals, initial letters of the owner and gardener. A very full description of a Roman garden is given by Mr. Moule in his "Essay on the Roman Villas."

**Potato for Garden Culture** (*An Old Subscriber*).—In reply to your query for the "best early, dwarf-growing, prolific, disease-resisting, general crop Potato for garden planting," we doubt if any variety better combines all those qualities than Myatt's Prolific Ashleaf, Rivers' Royal Ashleaf, or Gloucestershire Kidney, for all these, if raised from true stocks, are identical. That it is dwarf and prolific is well known, and it is generally ready for digging before the disease occurs; at least this is our experience. We find also that the tubers are as good in quality now as they were in the autumn, and they will continue good for a long time. We have for some years relied on this variety for our early and general crop under garden culture, and it has never failed to answer our expectations both by its yield and table quality. Your mode of wide planting is good, but with this variety the rows may be 6 inches closer than you name, and the other crops between the rows will succeed equally well. The time and depth of planting should be governed by the state of the seed and character of the ground. As a rule early and rather deep planting is the best in light, dry, and sandy soils, later and shallow planting in strong loam; but on this point you cannot do better than continue the plan that has proved successful.

**Potting Begonias** (*C. Diamond*).—We presume you mean the tuberous varieties. It is not too early to pot them provided you have a suitable position for starting them into growth, such as a heated pit or propagating house. They should be potted in a compost of equal parts of loam, peat, and leaf soil, with a free admixture of silver sand, each tuber being surrounded with sand and placed in the centre of a small pot. If the pots are plunged in cocoa-nut fibre refuse or sawdust of a temperature of 75° to 80°, it will be of great assistance to them, as if the plunging material is kept moist it will not be necessary to water the soil in the pots—a point of some importance, since, unless the greatest possible care is exercised in applying water to the tubers, a number of them will decay. The soil should be moderately moist when used, and the temperature of the house kept at about 70°. When growth commences raise the pots and place them on the bed for a few days, then remove them to a shelf near the glass, and as soon as the roots can be seen protruding through the drainage shift the plants into larger pots, and grow them in a light position in a house having a minimum temperature of about 60°. When artificial heat cannot be afforded to the extent and in the manner indicated, the tubers must not be potted so soon. If they have to be started in an ordinary greenhouse, the middle of April will be soon enough for potting; if, however, they are established in pots in which they were grown last year, it will be a safe plan to allow them to start in these pots, shaking them out carefully and repotting when the growth is half an inch long. A hothead, such as a Cucumber frame, will then be of considerable assistance in the early stages of growth, but they must not remain in such a frame to be drawn up weakly.

**Repotting Adiantums** (*Idem*).—The plants should not be potted until they have commenced producing young fronds freely. This is usually during February or early March, according to the condition of the plants and the temperature in which they are placed. Suitable soil is light turfy loam, peat, and leaf soil, in equal parts, with a plentiful admixture of broken charcoal and silver sand. This is good for young plants, which also will grow freely in peat alone; but for strong healthy plants a stronger compost is preferable. We never had them so fine as in two-thirds of rough turfy loam and one-third of the refuse of a Mushroom bed—old horse manure—with plenty of broken charcoal, and a handful of soot to a gallon of soil; but for young and delicate plants this compost is too strong and rich.

**Cucumbers and Melons** (*Melon*).—Such a house as the one represented in the sketch you have enclosed is a very good one for the purpose provided you have sufficient top heat, which you do not mention. The provision for bottom heat is ample; indeed we should prefer to have some sliding shutters in

the pit wall next the pipes, so that you could regulate the bottom heat as desired. You had better place a few inches of clinkers or other rubble on the floor of the pit, and cover them with turves or a thin layer of litter or leaves before placing in the soil. In the first instance this need only be spread about 3 inches deep, and at intervals of 2 or 3 feet form hillocks, each containing half a bushel or a little more of soil, in which the Cucumbers and Melons are to be planted. The first layer may be of ordinary garden soil, the mounds being of turfy loam with a fourth of decayed manure, and wood ashes if you have them. As the roots protrude through the hillocks they must be covered with warmed soil an inch or two at a time as often as is requisite. The soil for the Cucumbers as they attain strength should be rough, open, and rich, that for the Melons heavier, less rich, and pressed down very firmly. By adding soil as directed throughout the season, it is surprising how little is required to produce heavier crops with the aid of liquid manure and otherwise good culture. One of the finest crops of Cucumbers we ever had was produced from soil only a foot thick, but it was good soil, and more would have been required of a less sound and fertile compost. The minimum temperature of the house should be 70° for raising the seedlings. If you have a frame in the house, or handglasses placed on the warmest part of the bed, you will raise the plants more readily, and can strike cuttings much more freely than in the open bed. Cucumbers and Melons are usually ready for planting out a month after the seed is sown. Great care is needed in ventilation and watering, cold currents of air and cold water being fatal to the plants. For further details of culture see past issues under the heading of "Work for the Week," and the subject will be alluded to from time to time in future issues of this Journal.

**"Butter Nuts"** (*F. R.*).—The nuts you have purchased under the above name are produced by a South American tree, known by botanists as *Caryocar nuciferum*, though several other species also bear edible nuts. The tree which produces the Souari or Butter Nuts attains the height of 100 feet, the trunks rising like columns without branches to the height of 80 feet. Though it is a native of the South American provinces of Essequibo and Berbice it has been introduced to some of the West Indian Islands, and it has received especial attention in St. Vincent. The kernel is white, soft, and fleshy, with the mild flavour of a Sweet Almond, but much softer in texture, melting like butter, and is enclosed in an exceedingly hard shell. The wood of *C. nuciferum* is also employed in ship-building, and an oil is extracted from the nuts. Owing to the great height of the tree the nuts are only procured with considerable difficulty, which is partially the cause of their being seldom seen in this country.

**Wooden Hive** (*Henry F. Fox*).—Your larger sketch gives an ancestor of the Stewarton hive and now quite out of date. The smaller sketch is no doubt an "adapting board," the hinged part to be turned back at the time that glasses are placed over the six holes. Both belong to a past school of bee-keeping, and we should advise in the interests of economy that neither be used.

#### COVENT GARDEN MARKET.—FEBRUARY 2.

BUSINESS remains quiet, with no alteration to quote with the exception of Cucumbers, which have experienced a great fall.

#### POULTRY AND PIGEON CHRONICLE.

#### WEEDS OF THE FARM, AND HOW TO DESTROY THEM.

WEEDS of the farm are very numerous, and their individual names are also various in certain districts. We hope, however, to be able to describe most of them under their provincial names, so that, together with their habits of growth, colour, &c., they may be easily recognised by the home farmers in their respective localities. It must be admitted that it is necessary and desirable

in the interest of the occupiers of land and its general management, whether of arable or pasture and park lands, that the best methods of destroying weeds, and the injury they do to the corn and cattle of the farm, should be well defined and understood. To keep land free and clean from weeds is the broad basis of all good farming; but it must not be imagined that weeds can be destroyed in the same manner that we dispose of hedgerows—by grubbing and removal, because we find that practically the soil is charged with seeds of weeds, for we have seen various weeds spring up on soil removed from wells soon after its exposure to the air. We also recognise this matter in our ordinary modes of cultivation, for having destroyed the weeds down to the depth of the ploughing we no sooner bring up fresh soil than we have to do battle with a new army of them. We should also endeavour to cultivate the land as in a great measure to destroy those which exist only under certain conditions of the soil. For instance, on soils deficient in chalk and lime weeds often overrun all the crops of either corn or roots, especially in sandy soils, so that the prevention of their growth is the first point to be considered. It is in such a case clear that their prevention of growth is easier than their destruction by the ordinary means in use for that purpose—namely, the horse hoe, hand hoe, and the weeding hook, as well as the lately improved machinery.

We commence with a few observations on that destructive weed called Couch or Twitch Grass, and with which most individuals connected with agriculture have from time to time become too well acquainted. Although we have been told by eminent men who have explored the antipodes that there are soils and countries free from this pest, yet wherever a white man puts his foot Couch Grass or its kindred weeds will immediately show themselves. There are several species of Couch Grass, the two principal being the deep white-rooted and the surface-rooting or tendril-like Grass, which is frequently called Water Grass. To eradicate or keep down these weeds we must be on the alert at all times, and use all means within our reach. If there be one way better than another it is by employing surplus labour during the winter months to fork them out from the root crops. Unless this plan is resorted to, the land in many localities, notwithstanding whatever may be done by way of autumn cultivation or cleaning in the spring, will always prove a serious drawback, and the expense of forking-out the bunches of white-rooted Grass will be far less than leaving the land to be cleaned in the ordinary way in after years, quite irrespective of the delays of seed time.

We now pass to the weeds called Charlock and Wild Mustard; in fact, we have a wild Radish with a pale blue flower, of the same habit of growth and propagation peculiar to some soils. These are unwelcome weeds at all times, but especially to those who occupy upland farms on the chalk hills and on the stone brash formation. These weeds are very difficult to eradicate, as the seed lays dormant for a long period; but as soon as the land is brought into good tilth vegetation commences. When they appear in the root crop we can do battle with them, where the roots are drilled by the horse and hand hoe with good effect, especially if the roots are grown on the stretch. When these weeds take possession of young Barley or Oats they become very troublesome; and some thirty-six years ago Mr. Baker, who wrote the prize essay on the farming of Essex for the Royal Agricultural Society of England, alluded to the impossibility of destroying Charlock in the Barley crop. He, we suppose, wishing to make a virtue of a necessity, advised its being allowed to stand and seed with the Barley until harvest, and that the best malting samples of Barley frequently occurred when held up by Charlock. It is, however, now, we are pleased to say, perfectly easy to destroy these weeds by the new implement called the "weed eradicator," drawn by one horse, and the result was explained under the heading of "Agricultural Implements" in this Journal on page 36.

Wire weeds, of which there are at least two varieties—one growing with a small and short-pointed leaf and fine branches, but not reaching very far; the other having a larger and longer leaf, with very stout strong stems, and extending several feet; in fact, we once pulled a single root growing in some Beans, which was a perfect mat of stems 7 feet across, and weighed 9 lbs. These are usually most prevalent upon land requiring chalk; it is therefore advisable to chalk or lime the land, in order to prevent the necessity of waging a constant war against them on the land under root cultivation by horse and hand hoeing. They are, however, far more troublesome and damaging in the Barley crop than in any other, for where they prevail and the land is seeded with Clover in the Barley, the Clover is frequently overpowered and completely destroyed, being at the same time detrimental to the crop of Barley. When the Barley is drilled at 9 or 10 inches apart the land may be horse-hoed or hand-hoed should the weather be favourable, and the Clover seeds sown immediately afterwards. Wire weeds,

unfortunately, run along on the surface of the land, and in consequence the "weed eradicator" cannot touch them; they are therefore more difficult to destroy than Charlock, which grows erect and blossoms quickly. This leaves the home farmer no alternative but to apply chalk or lime, or run the risk of unsuccessfully attacking them with the hoe.

Another very difficult weed upon sandy soils is that commonly called "Bunting." It is a very small plant with a very minute white flower, and unless it is destroyed in the early stages of growth it will impoverish the soil and impede the growth of vegetable or cereal crops, and frequently destroys them entirely, especially if the season is adverse for hoeing, as it seeds very quickly. As a preventive is better than any labour for its destruction this can be effectually done by a liberal dressing of chalk or lime, after which, if a few plants appear, they are easily destroyed by the ordinary process of hoeing.

Chickweed is another enemy of the farmer, especially upon some soils, where it almost stops cultivation, particularly on fenlands in different counties. It is, however, well known to cultivators of gravel and dry loamy soils, and it is one of the most difficult to destroy by ordinary hoeings, as the slightest shower will set the plants growing again. The only time when it is likely to yield and die after the hoe is when the plants are in the second leaf, and even in that case if showery weather continues they cannot be destroyed.

Docks are also troublesome, and without careful management and constant removal from the soil will propagate in the most extraordinary manner. This weed is said to be indigenous to some soils, but we contend that the way it is often found to make its appearance is in consequence of seed being brought up from the subsoil after deeper cultivation. We have noticed on clay soils in Buckinghamshire and various other counties that in very dry weather these tenacious soils crack open, leaving wide fissures; and at the harvest time in the act of cutting the crops, if the Docks have been left, the seeds fall out into these openings, so that on the return of moist weather they close in upon the Dock seeds, which in consequence remain at various depths without vegetating, until by tillage they become exposed to the sun and air. We have noticed that this weed is often very carelessly left to seed at the sides of the widest water-carriers in the irrigated meadows, and after dropping their seeds the next flooding of the meadows distributes them far and wide.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—The work to be done by the horses will depend greatly upon the weather. When the land is dry enough chalk carting and spreading may be done with advantage, about 18 or 20 yards per acre being sufficient; also, carting yard, box, or town dung may be done upon the Clovers. In the other case, should flooding rains occur, the carting of roadside earth may be done, also the carting of chalk from the pit to a heap in the field where it will be required to be laid out at a future time. It must be remembered that the best and softest chalk should be selected, because it will always act upon the soil a year or two quicker than the hard, rubbly, and stone-like chalk. This is the time when the home farmer if he has roots or vegetables for sale can dispose of them to the best advantage; for instance, a salesman advertises that he requires to purchase 100 tons of red Carrots, and as these are frequently worth from 50s. to 60s. per ton at the nearest railway station such a sale would make a favourable item on the farm balance sheet. This only makes our advice good on the growth of such roots and vegetables as may be not only fit for use upon the farm in feeding cattle, but ready for sale as food for the people in times of scarcity. The matter has been recently alluded to by a farmer who had grown Cabbages and sent them to the London market, for which he had but little return in money, and he proceeds to caution his brother farmers as to the bad policy of growing roots or vegetables upon the farm for sale. This farmer erred by sending his vegetables to market at a time when they were worth but little, whereas if consumed upon the farm they always maintain a value easily reckoned. Besides, the farmer has the advantage, if he used it, over the market gardener, inasmuch that he can always consume his green and root crops without loss upon the farm; but not so the market gardener, because he grows his vegetables for sale only, and whether cheap or dear he has no other mode of disposal of his produce, thus showing that the home farmer, where so situated as to be near towns or railway stations, is in a better position to cultivate root and vegetable crops than the market gardener.

We have always recommended that horses employed in the tillage of the farm should in the winter months receive a moderate allowance of roots as part of their daily food, for in our own practice we found many years ago that to keep horses entirely upon dry food during winter and early spring impairs their constitution, weakens their muscular power, and often shortens their lives. The best food for

farm horses at this time of year as a weekly allowance is 1 bushel of Oats, 1 bushel of Maize, from 70 to 80 lbs. of roots either pulped or grated and mixed with sweet Oat straw chaff, and when the spring work comes on hay chaff, either of Clover or Saintfoin. Another important point in horse management is never to allow them to drink at either pond or trough, for the quantity of water they take cannot then be regulated. In our practice we always made the teamsmen carry them water in a bucket in the stables. In this way they are sure never to have too much; besides which, it is evident they do not require so much to drink when they receive roots in winter and green fodder in the summer. When horses in summer come in from severe field labour in hot weather they are very apt to drink too much if allowed to drink at a pond, and this is frequently the cause of broken wind; but we fear it is seldom considered so by either farmers or teamsmen. Farm horses are very subject to what is termed grass humour, indicated by severe swelling of the legs, particularly the hind legs and thighs, and this complaint is generally promoted if not induced by a sudden change of food from a long continuance of dry food only to that of gross and succulent green fodder. The chance of their suffering from this humour is, however, greatly diminished by the feeding with roots throughout the winter and spring, the best root food for horses being Carrots first, then Swedes, and Mangold as the spring advances. An odd horse or horses upon the farm, especially if they are strong and active, are as essential as any other horses, or more so. Mules are frequently used for odd work if large upstanding animals can be obtained, as they are not subject to the ordinary complaints of farm horses, and they are particularly handy for hoeing the root crops and all light work on the farm.

**Hand Labour.**—Spreading and breaking chalk, spreading dung on the Clovers, will now be required where the weather has permitted its being laid out. Farm roads should now be kept in shape by lowering the water tables, and then gravel will seldom be required upon private or roads leading from field to field. The lambing folds will require constant littering, but more especially it is requisite to enable the water to escape freely by cutting trenches on either side; they will, however, require but little attention in this way if they have been made on slightly sloping land. It is extremely desirable that water should escape freely, for the sheep are still very subject to lameness and foot rot if allowed to lie on wet ground or sodden littered folds. Some of the forwardest of the male lambs will soon be old enough to be castrated. This is best done when they are about a month old, and we prefer the cutting and searing plan to the old-fashioned system when we used to draw without searing at about a week old. It is found that the first-named plan is best, because the animals prove, either for fattening or for stock, more fleshy and fuller over the back and neck as well as under on the thighs and flank. These matters are now of more consequence than ever.

### VARIETIES.

**THE LIVERPOOL POULTRY SHOW.**—We often hear of poultry shows in large towns completely failing to attract the general public. Such does not seem to have been the case at Liverpool. In spite of intense cold during the first day, and rain and drizzle the second, the poultry show held there last week was visited by near four thousand people.

**POULTRY AND THE FROST.**—On the 17th ult., at 8 A.M., a thermometer outside a south-west window of my house registered 28° or 29° below freezing, and one to the north was at zero. This is most unusual cold for the Thames Valley. Eggs were cracked in the nests; and my hens, which had laid well up to that date, have all ceased laying, though warmly housed and well fed.—T. P. F.

**"THE ILLUSTRATED BOOK OF PIGEONS"** (Cassell, Petter, Galpin, & Co.).—We have received the first number of the new issue of this, which is now the standard work upon Pigeons. It is being republished in twenty-five shilling parts, and with the exception of some few corrections of misprints, &c., will, we believe, be precisely similar to the first issue. The illustrations in this part represent Antwerps and a Black Carrier, and are alone worth the money charged for the part.

**BIRMINGHAM DAIRY SHOW.**—At the last meeting of the Prize List Committee the days on which the Show should be held were fixed for Tuesday, Wednesday, Thursday, and Friday, June 7th, 8th, 9th, and 10th. The prize list was settled subject to confirmation at the general meeting on February 10th, and is on a very liberal scale. The cattle classes comprise:—Shorthorns eligible for herd book, Shorthorns ineligible, Ayrshires, Channel Islands, other breeds (pure and crosses). There will be numerous prizes for cheese, with separate classes for Stilton, Cheshire, Cheddar, Derby, Leicester, cream or soft cheese; besides the foreign varieties, America, Gorgonzola, Gruyère, &c., and champion prizes. Butter (fresh and cured),

British, Irish, and foreign; eggs, incubators, and poultry-feeding appliances, will all be recognised; as also bee hives and honey. A special feature will be the competition in cheese and butter-making appliances, milk vans, cans, purifiers, &c. The poultry prizes will include all the principal breeds kept for farm use, excluding the fancy varieties, and numerous prizes are to be offered for dressed fowls, chickens, and Ducks. Most of the premiums are open to general competition, but some classes are confined to the county of Warwick.

**SELECTING STOCK.**—"One of the greatest faults in selecting stock is that of large bones. A great bone in cows, pigs, or sheep is a great evil. It is an index to coarseness everywhere, and often the index, too, of a bad constitution. Size and strength are not identical in living tissues and structures. The small bone of the gazelle and the chamois, supporting them in dashing leaps from crag to crag, are natural illustrations of how strength may be condensed in the small bone. The large bones are full of cells—are porous, so to speak—and bear about the same relation to the small bone as the branch of the pithy Alder tree does to the dense and compact stem of the Oak."—(*Prairie Farmer*.)

**"CASSELL'S COOKERY BOOK."**—We have received the first part of the third issue of this work, and there are twelve other parts to follow. It is a cheap and excellent work, and it well deserves the success it has attained. It combines quality with quantity, and is worthy of a place in every home.

**THE IRISH FARMERS' GAZETTE.**—Mr. James Macdonald, formerly of the *Scotsman*, has been appointed to succeed the late Mr. R. O. Pringle as Editor of the above paper. Mr. Macdonald has on four different occasions carried off the Highland and Agricultural Society's prize of £30 for an essay on the agriculture of a specified county—viz., Caithness in 1874, Fife 1875, Ross and Cromarty 1876, and Sutherland 1879. He also received a gold medal from the Highland Society for a short essay on "The Agricultural Colleges of the United States and Canada, with reference to the Introduction of Agricultural Teaching into Scotland." In 1878 Mr. Macdonald was commissioned (along with his brother) by the Royal Agricultural Society of England to draw up a report for the Journal of that Society on "The Agricultural Features of the Paris Exhibition;" and for this report the two brothers received a premium of £150. Mr. Macdonald has also won the prize of £30 offered by the Highland and Agricultural Society of Scotland for the best essay on the agriculture of the counties of Forfar and Kincardine, making the fifth of these prizes since 1874. These honours afford sufficient evidence of the capability of this gentleman for discharging the important duties he has undertaken.

### FAMOUS POULTRY YARDS.

GRASSENDALE PRIORY (R. E. HORSFALL, ESQ.)

THERE are famous poultry yards which are known rather for quality than for the number of their tenants. Such is that of Grassendale Priory. All fanciers who frequented poultry shows a few years ago, or even casually looked over prize lists, must remember the invincible Light Brahma cock, "Sam" by name, the most perfect specimen of his race we have ever seen—champion in one season at the Crystal Palace, Birmingham, and Bristol as the best bird in the whole show. Grassendale Priory was his birthplace and home, and there live his descendants, for Mr. Horsfall is faithful to his one favourite variety, and breeds it really scientifically. There is much practical use in the description of such a yard as this. We have tried to picture establishments in which almost countless birds are reared for use and amusement, and roam over parks and woods; but arrangements so perfect as those at Grassendale for the cultivation of one breed we have never seen; and what makes them the more interesting is they are the gradual result of much thought, experience, and intelligence. Many of the houses Mr. Horsfall has made himself, and they are not like some of the so-called "model" establishments which rise on an unlimited carpenter's order, and

never fulfil well the purpose for which they are destined. We must not, however, generalise, but go through the yards in detail.

From gardens and hothouses innumerable, the description of which might form a charming chapter in other columns of this Journal, we come to the first cluster of runs. A large grass plot surrounded by trees and hedges has been divided into four pretty green yards. Privet hedges are planted in them against the fencing, which serve at once for ornament and shelter to the birds. Each yard has its house and dusting shed, and what strikes us specially in all the houses is their plain and substantial make, every one having a perfectly watertight iron roof. In them are pens of Light Brahmas, all mated with some particular object. Mr. Horsfall knows the pedigree of each bird, and looks for some particular excellence from every union. As in all yards and lofts where science is brought to bear upon breeding, some of the birds show what an ignoramus would call glaring faults, but which an experienced fancier knows to be valuable points in breeding stock. At the end of these runs is a row of substantial brick houses, each with a large covered aviary in front. These were the first poultry houses before their occupants rose to exhibition fame. Beyond them we come to three more large sheds, all dry and well lighted. Their floors are cemented and covered thickly with road grit, and exit can be given from all of them into a small grass run. They are employed for moulting adults and early chickens. In one is a magnificent old cock who has hitherto refused to discard some of his last year's plumage; in another the four first chickens of the year. From these a path leads to a field of three or four acres, a large portion of which is divided into twelve uniform runs, six on each side of a central walk, fenced about 4 feet high with boards and wire netting. The houses are built in pairs, each with a dusting shed on its outer side, and all are numbered. This field is on the north side of a wall, and so is chiefly used as summer quarters for the poultry. The chief sight, however, of all the establishment is a long airy house leaning to the wall. It is well lighted, and has a central passage from end to end and pens on each side—not cramped little exhibition cages, but about twenty real big pens. On the side towards the wall they are in two tiers, the lower for moulting fowls and sitting hens, the upper for trying and judging birds. On the other side is a single row of still larger pens, like small loose boxes, in which two or three exhibition birds can be kept on straw for a few days before show or housed in such weather as we have lately had. The roof is boarded, then covered thickly with straw and corrugated iron above, which Mr. Horsfall prefers to all other roofing as absolutely watertight. We cannot conceive a more perfect place for an amateur to attend personally to his fancy stock. Here ends the poultry yard, but not all connected with the poultry.

Mr. Horsfall has invented an incubator and a regulator for it; his gradual improvements may be seen in two or three machines made under his direction. Artificial mothers, too, he has; and it should be noted that during several seasons every bird at Grassendale Priory, including many renowned winners, has been reared artificially. The system seems to suit Brahmas, we fancy not all breeds.

Such is a yard which covers no great area, which has not involved any lavish expenditure, but which is, we believe, as perfect for its purpose as any in England.—C.

#### YEOVIL SHOW.

THIS, the fourth annual Exhibition of the Yeovil and Somerset County Poultry, Pigeon, &c., Association, was held on the 26th and 27th ultimo. The weather was unfavourable, the frost preventing some of the exhibitors from sending, while the rapid thaw on the first day of the Show acting upon the heaps of snow which covered the streets made progression a matter of difficulty. Mr. Leach, the Secretary, was indefatigable in his exertions, and the birds were thoroughly well cared for. Owing to the absence of the Rev. G. F. Hodson the major part of the poultry judging fell to the lot of Mr. Dixon. Mr. Sainsbury took the Waterfowl; Messrs. H. Allsop and T. C. Burnell judged the Pigeons, and the last-named gentleman also relieved Mr. Dixon of a few of the poultry classes.

The poultry were on the whole a good collection, and numbered 460 pens in the open and 170 in the local and selling classes. The schedule opened with—

**DORKINGS.**—*Coloured* (fourteen), which were only moderate in quality. First and Dorking cup (Synes) were both rather slight, and the cock was splashed on breast and poor in feet. Second (Newick) a larger pair, good in most points but too long in leg. Third (Newick) of similar stamp. The cock in pen 1 (Snell) was far the best Dorking in the class, but had dark feet and swollen toes; h.c., Phillips, Thomas, Gibbs, Radclyffe (2), Hamilton; c., Hamilton. *Any Other Colour* (seven) were a poor class. First (Coles) poor Silver-Greys. Second (Cresswell) Silvers again, the cock very defective in colour. Third (Hayne) the only pen of Whites in the class and not good, the cock having an inferior comb; h.c., Radclyffe; c., Plummer.

**COCHINS.**—*Cinnamon or Buff* (seventeen) were a fairly good class. First and cup for Cochins and Brahmas (Nickolls), Lemons, the cock fairly even in colour but too small, the hen shapely and well fluffed out. Second (Tomlinson) a moderate pair of medium colour. Third (H. G. Nicholls), the cock rather too much tail, but with perfectly feathered locks; the pullet wanting in shape and foot-feather; v.h.c., Clatworthy (an evenly matched pair of medium colour,

might have stood higher), Harris; h.c., Ruudle, Fowler, Bloodworth. *Any Other Variety* (fifteen) were the best class so far. First (Burt) good Whites, medium size, heavily feathered and hocked. Second (Beckerley) Partridge, fair in colour and marking, the cock rather wanting in foot-feather. Third (Darby) Whites, the cock beautifully clear in colour, the hen quite out of sorts; v.h.c., Snell, Andrews, Southern, Clatworthy, Rouse, Turner, Tomlinson; h.c., Fowler. Mr. G. H. Wood's pens in this and several other classes were empty.

**BRAHMAS.**—*Dark* (ten).—After the winners only a poor class. First (Joyce). The Palace cup cock mated with a small hen, very clearly marked on breast, but rather brown in ground. Second (Mrs. Turner) a moderate pair, the cock heavy in comb, splashed on breast, and heavily hocked; hen clear in colour, but wanting in marking. Third (Wheaton) only a moderate pair again, the pullet nicely marked, but too long in leg and back, and shallow; v.h.c., Wheaton (a shapely well-marked pullet); v.h.c. and h.c., Doel. *Light* (sixteen).—First (Holmes) a fairly good large pair, the cock rather yellow, and only moderate in comb. Second (Doel) of medium quality, the cock blind of one eye. Third (Snell), the cock very neat in head and stylish, but showing far too much black; the pullet poor; h.c., Doel, Turner, Drummond, Stratton.

**GAME.**—*Black Red Cocks* (twenty-three).—A very strong class. First (Tyler) a stylish bird, long in reach and in fine condition, but showing too much brown on breast and fluff. Second (Morris) a smart hard-feathered one, better in colour, a trifle flat in shin. Third (Mudford) a powerful-looking bird, long in reach but brown in fluff; v.h.c., Shawyer, Tyler; h.c., Place (2), Giles, Pashley, Mudford, Hopkins, Theobald, Fox, Tyler. *Hens* (twenty-four).—A good class, but not up to the last. First (Mudford) a shapely hard-feathered bird of good colour. Second (Tyler) a reachy pullet not quite so good in colour. Third (Tyler) long in reach but hardly style enough; h.c., Snell, Westcott, Hopkins, Alford, Hussey, Merrett, Fox, Tyler. *Brown Red Cocks* (eleven).—A good class. First and Game cup (Mercer) a somewhat leggy bird with a good eye and nicely laced breast. Second (Huxtable) stylish, and with a laced breast again. Third (Dance) not dark enough in face, and flat in shin; h.c., Hower, Dance, Snell, Morris, Dunstan. *Hens* (eleven) were another good class. First (Mercer) long in reach and hard in feather, of nice colour. Second (Dunstan) another of similar type but not so stylish. Third (Huxtable) hard in feather but deficient in style; h.c., Smith (2). *Any Other Colour Cocks* (eleven).—A fairly good class. First (Colgrove) a good yellow-legged Pile. Second (Huxtable) a stylish Duckwing. Third (Phillips) a Duckwing again, fine in head and long in reach; v.h.c., Lee (Duckwing); h.c., Theobald, Snell, Morris (all yellow-legged Piles). *Hens* (twelve).—First (Huxtable) a Duckwing, very good in colour. Second (Colgrove) a moderate yellow-legged Pile. Third (Phillips) a Duckwing again; h.c., Snell (yellow-legged Pile), Marley, Huxtable, and Tyler (Duckwings).

**HAMBURGINS.**—*Gold or Silver-pencilled* (seventeen) were a good class. First (Greenham) Golden, neat in comb and lobe and bright in colour. Second (Rawnsley) well-known Silvers. Third (Bell) Golden with fair combs and good lobes; v.h.c., Callcutt & Bell (Golden); h.c., Snell (Silver), Neal, Riddell, and Larcombe (Golden). *Gold or Silver-spangled* (ten) were a moderate class. First (Sutton) a nicely-marked pair of Silvers, moderate in comb and lobe; in fine condition. Second (Rawnsley) good Silvers again, the cock too heavy in comb. Third (Harris) moderate Golden; v.h.c., May; and h.c., Ashworth (Golden); h.c., Ashworth & Harris (Silvers). *Blacks* (thirteen) were another good class. First and Hamburg cup (Rawnsley) a very good pair in all points, and in great bloom. Second (Pettie) another fine pair close up to the winners. Third (Kellaway) in good condition, but the cock failing in comb and lobe; h.c., Lee, Bell (2), Ashworth.

**MINORCAS** (twenty-eight) were a wonderfully even class, but not of very first-rate quality for the home of the breed. First (Doel) a large fine pair with fair lobes, but both too heavy in comb. Second (Preby) very clear in lobe and in fine condition, but the cock white in flights and the hen white in fluff. Third (Elstou); the cock squirrel-tailed; v.h.c., Dominy; h.c., Clement, Watts, Neal, Baskerville, Honey, Harwood, Hawkins, Snell, Jones, Elstou, Tozer; c., Norton. **BLACK SPANISH** (three, had one pen empty). First-and-cup for the six classes from Minorcas to Silkies (Boulton) a very fine pair indeed. Second (Le Suenr); the cockerel held the same position at Birmingham; the pullet a good one.

**LEGHORNS** (twelve) were a poor class. First (Gibbs) moderate Browns, both too yellow in lobe. Second (Adams) Browns, the cock rough in comb and yellow in lobe. Third (Strong) poor Browns again, the cock very yellow in lobe; h.c., Williams (White), Stephens (Brown).

**HOUDANS** (thirteen) were a very strong class. First-and-cup (Nickolls) a large-sized pair of good colour, the cock rather heavy in comb. Second (Stratford) a fine large shapely hen with grand crest; the cock a trifle hollow in breast. Third (Howard) another good pair, the hen again being best; v.h.c., Fowler, Copplestone, Crookford; h.c., Thomas.

**LANGSHANS** (eight).—A moderate class. First (Bush) fair in size and in great bloom. Second (Buchan) not so large, and the hen rather uneven in comb. Third (Buchan) wanting in size; h.c., Bush.

**SILKIES** (thirteen).—A good class indeed. First (Cresswell) in nice feather and very neat, but rather too much of a canary shade for our taste. Second (Hudd) neat and pure white. Third (Cresswell) another very nice pair, very blue in lobe. 281 (Holmes) had combs and lobes of plain flesh colour; h.c., Goddard, Holmes, Darby, Ferris.

**POLISH** (eleven) were a good class. First-and-cup for Polish and three following classes (Rawnsley) well-known White-crests. Second (Huish) Golden, good in crest and colour, and fair in marking. Third (Huish) Silvers, very fine in crest, but deficient in marking; v.h.c., Ginton, Gawler (2), Bloodworth.

**MALAYS.**—*Any Colour Cocks* (fourteen).—A very good class. First (Joint) a reachy bird, with true Malay carriage, and in fine condition. Second (Waring) a Black Red in great bloom, and hard in feather. Third (Joint) a good one of the Dark sort, but one wing wrong; h.c., Shawyer, Waring, Huxtable, Tudrey, Richards, Joint. *Hens* (twelve).—First (Hosken) a rather heavy-looking bird of the Dark sort. Second (Huxtable), and third (Lecher) of medium colour, and better in shape than first; h.c., Bishop, Dowring (2, one being a good White); Evans.

**ANY OTHER VARIETY NOT MENTIONED** (fifteen).—First (Kilby) Plymouth Rocks, not yellow enough in leg. Second (Eyles) good Sultans. Third (Mauchiss) moderate Andalusians; h.c., Hewer, Symes, Adams (Plymouth Rocks), Vesey (Courtes Pates), Faye (La Flèche), Nicholson and Eyles (Sultans).

**BANTAMS.**—*Game.*—*Brown Reds* (eleven) were not a remarkable class. First (Osborne) neat and stylish, the pullet the best of the pair. Second (Chard) smart and hard-feathered. Third (Nicholls) reachy, but a little large; h.c., Cardell, Nicholls, Pashley, Mitchell. *Black Red Game* (twenty-seven).—A very good class. First (Allen) very shapely, hard in feather and good in colour. Second (Morgan) another very neat pair, not far behind the winners. Third (Hussey) rather loose in feather, and the cock carrying his wings rather low; v.h.c., Huxtable, Docksey, Dowell; h.c., Hore, Chard, Butt, Guin. *Game.*—*Any Other Variety* (twelve) were another good class. First-and-cup (Nicholls) a very smart pair of yellow-legged Piles. Second (Jones) very pretty Duckwings. Third (Hore) yellow-legged Piles again; another nice pair; h.c., Waters (yellow-legged Pile), Dowell (willow-legged Pile). *Black Rosecombs* (seventeen) were well

represented. First (Rawnsley) very clear in lobe and with neat combs. Second (Rundle) another smart pair, not so good in lobe. Third (Davies) the cock too heavy in comb; v.h.c., Wingfield, Ludlow, and Pearson; h.c. Bent. *Any Other Variety* (sixteen) were again a good class. First (Clarke) single-combed Cuckoo. Second (Rawnsley) White Rosecombs, good in comb, lobe, and colour. Third (Phelps) single-combed Cuckoos; v.h.c., Wingfield; h.c., Radelyffe and Miss Hubbard (Japanese), Miss Browne, Geary (2), and Pool (all Silver-laced).

DUCKS.—*Rouens* (nine) were not a remarkable lot. First-and-cup, Copplestone; second, Fowler; third, Nickolls; h.c., Snell, Dressing; c., Brutton. *Aylesbury* (eight) were only a moderate class. First, Hedges; second, Harris; third, Fowler; h.c., Snell. *Pekin* (twelve) were a good class. First (W. Nickolls) were perhaps the largest, but both second (Fowler) and third (Sutton) struck us as being better in carriage; h.c., Kellaway; c., Chubb, Baskett. *Any Other Variety or Ornamental Waterfowl* (eight) were well represented. First (Mr. Hayne) lustrous Black East Indians. Second (Pratt), and third (Miss Browne) were neat Carolinas; h.c., Mrs. Pratt (Whistlers), Linton (White Decoy), Brew (Black East-Indian).

## PIGEONS.

The open classes numbered 450 pens, and were, taking quantity and quality into consideration, one of the finest collections that has been seen in the West of England. In nearly all the classes the prizes went to birds that have been successful many times before, and are well known to fanciers.

POUTERS.—*Blue or Black Pied Cocks* (six).—First (Baker) a Blue, also took the cup for Pouters. Second (Fulton) a well-marked Black. Third (Baker) another good Black; v.h.c., Fulton (Blue). *Hens* (eight).—First (Fulton), second and third (Baker) were all Blues; v.h.c., R. Woods (Blue); h.c., Fulton (Black). *Any Other Variety Cocks* (six).—First (Baker) a Red Pied. Second (Fulton) a White. Third (P. Herrieff) a Red again; v.h.c., Baker (White). *Hens* (six).—First (Fulton) a Yellow Pied. Second (Baker) a Red Pied. Third (Baker) a Yellow Pied.

CARRIERS.—*Black Cocks* (nine).—First (Baker) took the cup for Carriers or Barbs, but was closely pressed by second (Fulton). This same exhibitor was placed third with a bird with wonderful wattle, but rather short in neck; v.h.c., Baker; h.c., Widger; c., Harris. *Any Other Colour Cocks* (three).—First (Fulton) and third (Widger) were Duns. Second (Baker) a very good Blue. *Any Other Colour Hens* (eight).—First, Mr. Baker's well-known Black. Second and third (Fulton) a Black and a Dun respectively; v.h.c., Widger (Dun); h.c., Widger (Black); c., Cooke (Dun).

BARBS (ten) were a very good class. First (Baker) and second and third (Fulton) were all Blacks; h.c., Sutton (Black), Pfefer and Baker (Duns).

TUMBLERS.—*Short-faced Almonds* (eleven) were another wonderfully good class. First (Fulton) a beautiful hen; also took the cup for Short-faced Tumblers. Second, Baker; third, Weston; h.c., Baker, Leith. *Any Other Variety of Short-faced* (ten).—First (Baker) a Red Agate, as also was second (Leith). Third (Fulton) a Kite; v.h.c., Weston (Yellow Agate), Baker (Red Agate); h.c., Hurdell and c., Weston (both Red Agates). *Balds or Beards Long-faced* (twelve).—First (Woods) a Blue Beard, also took the cup for Long-faced Tumblers. Second (Woods) a Black Bald. Third (Weston) a Red Bald; v.h.c., Mapplebeck (Feather-legged Black Bald); h.c., Hansford, Baker (Black Bald). *Any Other Variety Long-faced* (twenty-three).—First (Fulton) a Black Mottle. Second (Doughty) a Yellow Rosewing. Third (Wilkes) a Muffed Red Rosewing; v.h.c., Brunton (Red Agate), Doughty, Baker (Yellow Rosewings); h.c., Woods, Pfefer (Yellow Rosewings), Weston, Kohler (Red Rosewings).

OWLS.—*Foreign* (eleven) were all Whites with the exception of third, which was Black and White. First (Baker) also took the cup for Owls. Second, Woods; third, Fulton; v.h.c., Baker; h.c., Harvey, Billett; c., Wardle. *English, Blue or Powdered Blue Cocks* (ten).—First (Weaving) a powdered Blue. Second (Woods) a Blue. Third (Chipperfield) a powdered Blue; v.h.c., Von Senden; h.c., Stephens, Fulton; and c., Lewis (all powdered Blues). *English Any Other Colour Cocks* (ten).—First, Woods; second, Weston; and third (Andrews), as also all the other noticed birds, were Silvers; v.h.c., Van Senden; h.c., Weaving; and c., Brunton. *Any Colour Hens* (nine).—First (Weaving) a Silver. Second (Weston) powdered Blue. Third (Van Senden) a Silver; v.h.c., Lewis (powdered Blue); h.c., Fulton (Blue), Chipperfield (Silver).

DRAGONS.—*Blue or Black Bar Silver* (twenty-five).—First (W. Smith) a Blue, also took the cup for Dragons. Second (Lush); and third (Fulton) also Blues; v.h.c., W. Smith (Silver); h.c., Lush, Skinner, Waterman (2), Flanagan, Fulton, Whichelo, Allen (2), and Moody (all Blues), Close and Pfefer (Silvers). *Brown Bar Silver* (eight).—All the prizes went to Mr. Bishop, who also had three birds highly commended. *White* (eighteen).—First, Bishop; second, Berridge; third, Allen; h.c., Skinner, Bishop (3). *Any Other Colour* (twenty-two).—First (Close) a Yellow. Second (Leith) a Red. Third (Flanagan) a Blue Chequer; v.h.c., Widdows (Red); h.c., Leith, Stanhope, Elkington, Waterman, Widdows, Vicary, and Harris (Yellows), W. Smith and Allen (Grizzles), Jorden and Close (Blue Chequers).

JACOBS.—*Red or Yellow* (fifteen).—First and second (Weyman & Buchanan) a Red and Yellow respectively. Third (Fulton) a Red; v.h.c., Fulton (Yellow); h.c., Gould (Red), Sutton (Yellow); c., Baker (Red). *Any Other Colour* (twelve).—First (Fulton) which took cup for Jacobins and Fantails, as also second (Baker) and third (Roberts) were Blacks; v.h.c., Fulton; h.c., Weyman & Buchanan (2), and c., Andrews (all Blacks).

TURBITS.—*Blue or Silver Cocks* (five).—First (Fulton) a Blue, also took the cup for Turbits. Second (Baker) a Blue. Third (Baker) a Silver; h.c., Bulley (Blue). *Any Other Colour Cocks* (eleven).—First (Baker) a Red. Second and third (Fulton) Blacks; h.c., Cresswell (2, Blacks), Bulley (Yellow), Andrews (Red); c., Graham (Black). *Any Colour Hens* (seventeen).—First (Cresswell) a Black. Second (Lumley) a Blue. Third (Cresswell) a Yellow; v.h.c., Baker (Yellow); h.c., Fulton (Black), Stanhope, Rawnsley (Reds), Fulton, Lumley, Gregory (Blues), Billett (Silver); c., Bulley (Yellow), Billett (Blue).

FANTAILS.—*White* (fourteen) were a good class. First, Baker; second, Fulton; third, Baker; v.h.c., Loversidge; h.c., Cresswell (2). *Any Other Colour* (thirteen).—First and second (Cresswell) were Blues. Third (Dressing) a Black.

MAGPIES.—*Any Colour* (thirteen).—First (Stevens) a Black. Second (Mudie) a Red. Third (Harvey) a Black; h.c., Maurice, Stevens, Bulley (Blacks), Bulley (Yellow), Bulley, Phillips, and Beard (Reds).

SWALLOWS (eleven).—First (Bulley) a Red. Second (Bulley) a Black. Third (Sutton) a Blue; h.c., Allen, Tanner, Widdows (Blues), Stevens, Wardle (Blacks).

ARCHANGELS (twenty).—First, Allen; second, Ponnsett; and third (Allen) were all birds of great lustre; v.h.c., Stevens; h.c., Stevens, Webb; c., Allen.

TRUMPETERS (ten).—First (Baker), which also took the cup for Trumpeters, Magpies, Swallows, and Archangels. Second (Fulton), and third (Yardley) were fine Black Mottles; h.c., Wardle (2), Rowe (Black Mottles); c., Nicholls (Red).

ANTWERPS.—*Short-faced* (twelve).—First (Waterhouse) a Silver Dun, took the Antwerp cup. Second (Rayner), and third (Waterhouse) all Silver Duns; v.h.c., Rayner, and h.c., Turner (Red Chequers). *Medium-faced* (thirteen).—First (Rawnsley) a Red Chequer. Second (Thickett), third (Waterhouse), and v.h.c. (Wardle) were Silver Duns; h.c., Davis (Blue Chequer). *Long-faced* (six).—

First and second (Waterhouse) were Silver Duns. Third (Rawnsley) a Red Chequer. *Homing, Any Variety* (eighteen).—First (Turner), and second (Hewer) were Blue Chequers. Third (Fox) a Red Chequer; v.h.c., Crust (Blue Chequer); h.c., Pitcher, Leak (Red Chequer), Gillham (Silver Dun), Jenkinson.

ANY OTHER SHORT-BILLED FRILLED VARIETY (fifteen).—First (Waterhouse) a Blue Vizor, also took the cup for this and the next class. Second (Baker) a Turbitten. Third (Yardley) a Blondinette; v.h.c., Wardle (Blondinette) Baker; h.c., Allen, Lewis (Satinettes); c., Fulton (Blue Vizor).

ANY OTHER NEW OR DISTINCT VARIETY (thirteen).—First (Fulton) a Blue Frillhack. Second (Wardle) a Black Priest. Third (Yardley) a Laced Ice; v.h.c., Chevassé (Modena), Gatty (Fireback); h.c., Bulley (Blue Priest) Webb.

## PROFITABLE POULTRY.

THE following return of the number of eggs laid by my hens during the past years, and of the cost of their food, may be of interest to your readers:—

Month.	No. of Hens.	No. of Eggs.	Average per Hen.
January .....	29	107	3.68
February .....	29	171	5.89
March .....	37	527	14.24
April .....	35	407	11.62
May .....	35	359	10.25
June .....	35	264	7.54
July .....	35	266	7.60
August .....	35	133	3.80
September .....	35	178	5.05
October .....	30	9	0.30
November .....	28	12	0.42
December .....	28	60	2.14

This gives an average of 32½ hens through the year, and a total of 2493 eggs, value £15 9s. 1½d.

I have reckoned the price of the eggs as 1½d. each throughout. This sum I have always been able to obtain even in the season when eggs were most plentiful, and could doubtless have obtained double that price in the winter months had I been able to spare the eggs.

I account for the bad egg return from the month of August on to the end of the year partly by the fact that, owing to severe illness, I was unable to attend personally to the feeding, &c., of the birds, and partly by the fact that for the same reasons all the chickens of the year except a very few January pullets died. The January pullets moulted at the same time as the old hens, and I have come to the conclusion that for mere laying purpose it is unadvisable to hatch pullets earlier than March.

The cost of feeding during the entire year was £9 5s. 7d.; the feeding used was Wheat, Barley, Oats, pollard (or middlings), and a little Indian corn. The food of the chickens reared and which died is included in the total. The fowls had a house about 10 feet by 6 feet with a moderate-sized yard, but as a general rule they had the run of a grass field at the back. About eight of the hens are Leghorns, seven Minorcas, and the remainder crossbred.

It will be seen that I made a profit of £6 3s. 6½d. during the year, this of course without counting anything for rent or labour, or reckoning the scraps from the house as of any value. As my stock was about equal in numbers at the commencement and end of the year, that item need not be taken into account.—W. C. Dalkey.

## CAMBRIDGE SHOW.

THIS Show, which opened on Tuesday and closes to-night, possesses a special interest, inasmuch as the youngsters have a chance through the exclusion of the Palace and Birmingham winners in the poultry classes. The building (the New Corn Exchange) is admirably adapted for a show, and the arrangements were all that could be desired. The Secretary (Mr. R. Peters, jun.) and Committee have their hearts in the work, and the results are, as might be expected, a success. Exclusive of selling and local classes poultry had 323 entries; Pigeons 213. Mr. Cresswell judged all the poultry that were judged except Game and Game Bantams, which were taken by Mr. Entwistle.

BRAHMAS.—*Dark Cockerels* (seven).—Beyond the winners were not a strong class. First (Lingwood) a large well-feathered bird, black-breasted, rather coarse in comb, the unnoticed Dairy Show cockerel we think. Second (Comyns) a very shapely neat-headed hocked bird of silvery colour, but too small, and not quite black on breast. Third (Comyns) a neat head again, with a very small comb rather high behind; larger than but not so shapely as second. Fourth (Williams) neat-headed shapely bird, but rather dark on shoulder; not quite black under throat, and too much hock for his foot feather. *Pair of Pullets* (eleven) were a strong class, all the noticed birds being above the average in merit. First and Brahma cup (Lingwood) a very fine shapely pair, heavily feathered, with moderate hocks, well marked in the dark style, but rather brown in ground for pullets. Second (Lingwood) same type as regards shape but no hocks; lighter in ground, and pencilling indistinct. Third (Percival), one pullet good in shape and beautifully marked on a silvery ground, the other a very inferior bird. Fourth (Percival), both well-marked Silvers, but one wanting in solidity, and both deficient in feather; v.h.c., Holland; h.c., Comyns (2), Barclay. *Light Cockerels* (fourteen) were only a moderate class. First (Haines) very shapely and good in colour but hocked—an easy win. Second (Lucas) a stylish bird of this exhibitor's usual type, rather long in leg. Third (Haines), shapely and well feathered, but not pure in colour, and twisted in hackle. Fourth (Silvester) shapely but small, white in tail, and hocked; v.h.c., Lucas,

Collisham; h.c., Morgan. *Pair of Pullets* (eleven).—There were many good single birds, but they were badly matched throughout. First (Lucas), one wonderful pullet with the one fault of a not very clear hackle, mated with a large shapely one rather yellow in ground. Second (Haines) a large well-matched pair, rather coarse in head. Third (Collisham) a neat-headed shapely pair, but rather small. Fourth (Morgan), both good pullets, but badly matched; v.h.c., Morgan; h.c., Morgan (4).

COCHINS.—*Buff or Partridge Cockerels* (seventeen) were a wonderfully fine class. First-and-cup (Pye) a beautifully even-coloured Buff, grand in shape, locked with fine feather. Second (Clatworthy) another good Buff, not so solid in build as the first. Third (Brown) a very good Buff. Fourth (Clatworthy) a neat Partridge; v.h.c., Bloodworth (2); Clatworthy, Nicholls (all Buffs); Paxton (Partridge); h.c., Bloodworth (Partridge), Bullard (Buff). *Pair of Pullets* (ten) a moderate class.—First (Darby) large and well feathered, but not very even in colour, and high in tail. Second (Allerton) shapely Partridge, well marked and nicely fluffed out, ran the winners very close. Third (Bloodworth) moderate Buffs. Fourth (Bullard) large Buffs, failing in colour; h.c., Bloodworth (2, Buffs), Bullard (Partridge). *White or Black Cockerels* (four).—There being less than six entries, first was withheld. Second (Darby) a grand White very nearly up to the cupwinner. Third (Morgan) a fair White. Fourth (Lincolne) a poor Black. *Pair of Pullets* (four).—Hard luck again for Mr. Darby, first being again withheld. Second went to a very good pair of his Whites. Third (Morgan) Whites again, very bad in colour. (Fourth Lineolne) fair Blacks.

DORKINGS.—*Cockerels* (sixteen) were a good class.—First-and-cup (Swales) a large shapely coloured bird, good in all points. Second (Wood) a smart-coloured bird of the old sort. Third (B. Smith) coloured again, good in size, but rather long in leg and heavy in comb. Fourth (Woodgate) a very dark-coloured one, good in size, but too upright in carriage; h.c., Reed, Wallis, Woodgate (coloured); c., Atterton (2, coloured), Berry (White). *Pair of Pullets* (eleven) were a good class, made up entirely of coloured birds.—First (Wood) good in size and white in feet, but rather long in legs, and with white ears. Second (B. Smith) were of similar stamp, but even longer in leg. Third (White) a good-sized pair, one very dark in feet. Fourth (Mills) moderate; h.c., Darby.

FRENCH.—*Cockerels* (eleven).—A very good class made up of six Crèves and five Houdans. First (Fullarton) a large shapely Crève in fine condition. Second (Jackson) a Houdan of good size, but rather wanting in breast. Third (Carlton) a good-sized Crève, poor in crest. Fourth (Lamb) a small but neat Crève; v.h.c., Jackson (Houdan), Mackwell (Crève); h.c., Darley, and Palmer (Crèves), Howard (Houdan). *Pair of Pullets* (six) were for their numbers a very good class, all being noticed. First (Nicholls) a grand pair of Houdans. Second (Fullarton) fine Crèves, one pullet rather crooked in crest. Third (Markwell) medium-sized but neat Crèves. Fourth (Howard) very dark Houdans, good in crest and muffled; h.c., Palmer (Crèves), Thomas (Houdans).

GAME.—*Black or Brown-Red Cockerels* (fourteen) were a good class. First-and-cup for Game and Game Bantams (Fludger) a very stylish Brown Red, of great reach, and nicely laced on breast. Second (Martin) another Brown Red of similar stamp, but not so hard in feather. Third (Bothway) a close-feathered neat-headed Brown Red. Fourth (Adams) another good Brown Red; h.c., Adams; and c., Blood & Dames (Brown Reds). *Pair of Pullets* (seven).—Here again the Brown Reds had much the best of it. First (Bothway) stylish Brown Reds, hard in feather, and well shown. Second (Martin) of similar stamp, as also were third (Snell). Fourth (Merrett) moderately Black Reds. *Any other Variety Cockerels* (ten) only a moderate class. First (Bothway) a rather large yellow-legged Pile. Second (Mason) and fourth (Martin) were of the same colour. Third (Perry) a neat Duckwing. *Pair of Pullets* (two).—First and third withheld. Second (Perry) willow-legged Piles. Fourth (Snell) yellow-legged Piles.

HAMBURGS.—*Golden-spangled Cockerels and Pullets* (eight) only a very moderate lot. First (Jones) good in lobe and colour, but rather heavy in comb. Second, Jackson; third, Plattin; fourth, Digby. *Silver-spangled Cockerels and Pullets* (eight) were a rather better class, but heavy combs were too prevalent. First, Ashworth; second, Pointer; third, Stauwell; fourth, Digby. *Golden-pencilled Cockerels and Pullets* (sixteen) were a better class. First and Hamburg cup (Orriess) good in colour and marking, and neat in comb and lobe. Second (Castell) nice style and colour, but the cock red in lobe. Third (Carver), the cock bad in lobe again. Fourth (Ticknell) a neat pair; h.c., Brown, Robinson. *Silver-pencilled Cockerels and Pullets* had four entries, but two empty pens.—First and third were withheld. Second, Snell; fourth, Plattin. *Black Cockerel and Pullet* (thirteen).—There were four empty pens, and the quality of the rest was only moderate. First (Digby) stylish and in fine gloss, but rather heavy in comb. Second (Turner), third (Berridge), and fourth (Pointer) were all fairly good pens.

BANTAMS, GAME.—*Black or Brown Red Cockerels and Pullets* (eleven).—First (Hore) neat Black Reds. Second (Challands) reachy Brown Reds. Third (Ditcham) a very smart Black Red cockerel, mated with a moderate pullet. Fourth (Mills) Black Reds, in fine condition; h.c., Southwell (Black Reds). *Any other Variety Cockerels and Pullets* (six) were a fair class. First (Hore), Second (Goodbody), third (Miller), and fourth (Pearson) were Piles, alternately yellow and willow-legged.

SEBRIGHTS.—*Cock and Hen, any age* (seven), were only a moderate class. First (Morgan) Golden, second (Leno), third (Morgan), and fourth (Tearle) Silvers; v.h.c., Leno (Golden, perhaps the best in the class), Nixon (Silvers).

BANTAMS.—*Any other Variety and any age, not Game or Sebrights* (eleven) were a good class. First (Miss Hubbard) Japanese. Second (Mrs. Reed) Black Rosecombs. Third (Rhodes) and fourth (Tearle) both White Rosecombs; h.c., Atkins (Japanese), Digby (Black Rosecombs).

ASEELS.—*Cocks*.—First, Fellows; second, Bryan; third, F. G. Dutton; v.h.c., Bryan, Gatty; h.c., Carvill, Mann, C. Bunnett. *Hens*.—First, Peake; second and third, Dutton; fourth, Bunnett; v.h.c., Dutton (2), Sugden, Peake; h.c., Mann, Mills, C. Sugden.

ANY OTHER VARIETY.—*Cockerel and Pullets* (fourteen).—First (S. Smith) moderate Spanish; second (Ekins) good Frizzles; third (Jackson) Minorcas; fourth (Miss Portman) Andalusians; v.h.c., England (Silkies); h.c., Horner (Golden Polands), Moore (Minorcas); 322 (Waller) unnoticed, a really good pen of Spanish.

DUCKS hatched in 1880 *any Variety* (fifteen) were a strong class. First-and-cup (Morgan) Pekins, very good in colour and carriage. Second (Snell) good Aylesbury. Third (England) very lustrous Black East Indias. Fourth (Waite) Good Rouens; v.h.c., Bayley (Pekins), Rawson (Rouens); h.c., Bygott (Rouens), Portman (Black East Indian), Snell (Pekins).

#### PIGEONS.

ANTWERPS.—*Short-faced* (nine) were not a remarkable class. First (Weaving) a Silver Dun, an easy win. Second (Stanhope) a Blue Chequer. Third (Carter) and fourth (Weaving) Red Chequers. *Any Other Variety* (sixteen).—A fair class. First (Spink) a Red Chequer. Second (Dant) a poor Blue Chequer. Third (Tebbutt) a Silver Dun. Fourth (Denny) a Blue; h.c., Bracher, Coulson, Hinson (Blue Chequers).

CARRIERS.—*Cocks* (nine) a good class well placed. First (Baker) the champion Black. Second (Hale) a Black. Third (Hammond) a Blue. Fourth (Waldock) a Dun; h.c., Stocker (2, Blacks). *Hens* (thirteen).—After the winner a poor class. First, Mr. Baker's well known Black hen. Second (Denny) a Dun. Third (Hammond), a Blue. Fourth (Lass), a Black; v.h.c., Hale (Dun); Stocker (Black); h.c., Hollick and Hutt (Black); Leno and Kempton (Duns). *Cock or Hen hatched in 1880* (thirteen) a very good class. First-and-cup (Baker) a well-known Black. Second (Hale) a Dun. Third (Kempton) and fourth (Clifton) Blacks; v.h.c., Hollick (Black); h.c., Byford (Black), Hollick (Dun).

DRAGONS (twenty-two) a very good class. First (W. Smith) Blue, an easy win. Second (Waterman) Yellow. Third (Elkington) a Blue Chequer. Fourth (Greenhalgh) a Blue; v.h.c. and h.c., Atkins (Yellow); h.c., Berridge (White), Byford (Yellow), Waterman (2, Blue and Red).

POUTERS.—*Cocks* (eighteen).—This and the next class were the best amongst the Pigeons. First-and-cup for Pouters and Tumblers (Sugden), the Birmingham and Palace winner. Second (Herrieff) a grand Red. Third (Baker), the well-known Blue Pied Kilmarnock cock. Fourth (Byford) Mr. Pratt's old White cock; v.h.c., Sugden (Red); h.c., Sugden (Yellow), Ashton & Byford (Whites), Greenhalgh (Blue), Howard (Sandy), Herrieff (Red). *Hens* (fourteen).—First and fourth (Sugden) Blues. Second (Byford) a grand White hen. Third (Herrieff) Red; v.h.c., Howard (Yellow); h.c., Baker (Blue), Sugden (Red) Swan (White).

TUMBLERS.—*Short-faced* (thirteen).—A very good class. All the prizes went to Mr. Braid. First, an Almond hen; second, a Kite hen; third, an Almond cock, the Birmingham cupwinner; fourth, a Red Agate Mottle; h.c., Baker, Howard (Almonds); h.c., Braid (Almond), Langridge (2), an Almond and a Yellow Agate. *Any Other Variety* (thirteen).—A poor lot. First and second (Bowler), a Red Mottle and a Black Mottle; third (Braid), a Black Bald; fourth (Howes), a Blue Beard; h.c., Waterman (Black Mottle).

JACOBS (thirteen).—After the winner only moderate. First (Gould) a Red well placed. Second and third (Hammond) a Yellow and a Red. Fourth (Mann and Porter) a Yellow; h.c., Mann & Porter, Passmore, & Gould (Reds).

OWLS (fourteen).—A good class. First and third (Weaving) a Silver and a Blue. Second (Baker) White African. Fourth (Stanhope) Silver; h.c., Alford and Chipperfield (Blues), Langridge (Silver).

TURBIS (fifteen).—After the first three a poor lot. First-and-cup for last five classes (Baker) a Blue. Second (Sugden) a Blue. Third (Lumley) a Blue. Fourth (Tebbutt) a Yellow; h.c., Lumley (2), and Brampton (all Blues).

BARBS (six).—First (Baker) a well-known Black, easily ahead; the rest only moderate. Second (Hale) a Black. Third (Stanhope) a fair White. Fourth (Alford) a Black.

ANY OTHER VARIETY OF PIGEONS (fifteen).—First (Greenhalgh) a Red Swallow. Second (Elkington) a Frillback. Third (Baker) a Black Mottled Trumpeter. Fourth (Baker) a Blondinette; v.h.c., Ashford (Satinette), Rum-below (Blue Priest); h.c., Ashford (Brunette), Collingwood (White Fantail), Mudie (Red Magpie), Reid (Blue Runt).

#### OUR LETTER BOX.

**Artificial Hatching and Rearing** (*La Flèche*).—Through an oversight the temperature to be maintained during the first ten days of hatching was given on page 82 (last week) at 202°, it should of course have been 102°.

**Artificial Hatching** (*L. Malcolm*).—You cannot hope to attain any success by the method you indicate, you must procure a proper incubator. The hot-water pipes might be utilised for rearing the chickens, but to hatch in such a way is quite out of the question. As to the proper temperature see our article in last week's Journal. Books on hatching, &c., at present published, are "Hydro-incubation," by T. Christy, 1s. (Christy & Co., 155, Fenchurch Street, E.C.), "Practical Artificial Incubation," by E. Brown, 1s. (Cassell & Co., Ludgate Hill), and "Artificial Incubation," by H. Tomlinson (see advt. in No. 29 of Journal).

**Distinguishing Sex of Guinea Fowl** (*R. J. H.*).—There is no distinction between the plumage of the cock and hen. The male birds arch their backs and run along on tiptoe with a mincing air, they are also more vicious to other fowls than the hens; they also have larger wattles. The hen alone utters the peculiar cry which resembles the words "Come back." It is only by observing these points that you can tell which is which. In a state of nature Guinea Fowls pair. In confinement two hens are as many as you can safely put with one male bird.

#### REMARKS.

23rd.—Generally cloudy and calm, occasional sun, frost less severe.

24th.—Sharp frost, overcast and misty.

25th.—Very cold, but fine with bright sunshine.

26th.—Calm, overcast, sharp frost; milder in evening, silver thaw at night.

27th.—Thick fog in morning and thaw, fine in middle of day, misty again in evening.

28th.—Very damp, cloudy, bright at intervals.

29th.—Very mild, warm wind and rain, snow fast disappearing.

No frost after the 27th, but a gradual thaw with drizzling rain. The mean temperature of the week, notwithstanding the mildness of the last two days, was far below the average. The mean temperature of every day from the 5th to 27th was below the average; that of every day from the 12th to 27th was below freezing point. It was one of the most remarkable cold periods of this century, but shorter in duration than that of January, 1814.—G. J. SYMONS.

### THE CULTIVATION OF GARDENIAS.

**T**HE Gardenia as an evergreen stove plant ranks very highly in popular estimation, and is much admired by ladies for the purity and fragrance of its flowers, especially as they can be obtained during winter and spring. The blooms individually are only of short duration, yet they are produced in succession, and a large plant will have flowers during a period of some weeks. With a number of plants and plenty of room at command Gardenia blooms can be produced over a period of several months if care be exercised in preparing the plants and retarding them as the case may be. Their natural time of flowering under ordinary stove treatment will be through March, April, and May. To obtain them in autumn requires much time, room, and plenty of plants to work upon.

Propagation can be effected at almost any season of the year by cuttings. These are not difficult to strike either from the ripened wood or from young shoots. If rooted about August from half-ripened wood we have the whole of the following season in which to grow the plants; yet if rooted in January or February good plants can be grown to produce ten to twelve blooms each next spring. The cuttings are best inserted singly in small 2-inch pots, in a mixture of peat and sand, and plunged in bottom heat in the propagating frame or under a bellglass. If practicable, and bottom heat can be applied until August, the growth is much more rapid; this, however, is not necessary unless large plants are wanted quickly.

In preparing for potting, the pots should be carefully drained and a little moss or the roughest portion of the compost placed over the crocks. The new soil should be pressed firmly into the pots, so that water cannot pass through it and leave the old ball dry. Potting must be done with care. The system of using a sharp-pointed stick to set the roots at liberty when repotting cannot be too strongly condemned, as I believe more plants are destroyed through this than from any other cause, especially fine-rooted plants such as Heaths, and this applies with equal force to the Gardenia. The crocks only should be removed, and any loose soil from the top of the old ball. The time of potting varies, especially with established plants, and the period they are wanted to bloom. Some cultivators prefer potting as soon as blooming is over. The operation is best carried out as soon as the flower buds commence forming, for then Gardenias always unfold a number of leaves, and the roots are active and soon take to the new soil. The plants after flowering are ready to be cut back, and will start at once into vigorous growth without being again disturbed.

The compost suitable after the young plants are rooted is

rich fibry loam and peat in equal parts, adding a 6-inch potful of bone dust to every barrowful of soil, and plenty of coarse sand to make the whole porous. When the 2-inch pots are full of roots 4-inch pots should be employed, and afterwards the house or pit in which the plants are growing should be kept rather close for a week or ten days until the roots have taken to the new soil. The atmosphere should be moist and the plants well syringed overhead. The plants must not be allowed to suffer by want of pot room, and must be transferred into larger pots as required. Pots 6 or 7 inches in diameter will be large enough the first season, and bushy plants can be grown in those sizes if attention be paid to stopping the shoots as they grow.

If required to bloom the first season the growths should not be stopped later than the first week in August, but be allowed to extend, the plants being grown from that time under the influence of a little more air. Under these conditions young plants will soon complete their growth and form flower buds, averaging from ten to twelve upon each plant. These will unfold during March, or earlier if brought forward rapidly in brisk heat after the buds are set. If the object is to grow the plants to a good size as quickly as possible they should not be allowed to bloom, but be stopped later than the time named to prevent shortening the growths, which occurs by cutting the blooms; the plants then start early again the following year. If allowed to flower, and two or three months are thus lost at the commencement of the year, a much longer time will be required to have the plants of large size; and at this period when root-action has fairly commenced the plants should be placed in 8-inch pots and grown on under the same conditions as described above. This, the second season, they should make rapid strides, and be ready by the end of June to be placed in 10-inch pots provided every attention recommended has been carried out. Any shoots that require stopping should be attended to, and the plants be grown on rapidly under the influence of light and sufficient air to cause their growth to be short and possess that solidity which is essential for a good set of flowers. Potting twice in a season will not be necessary after the plants have attained a fair size. Ten and twelve-inch pots are large enough for all ordinary purposes. When placed in the last-mentioned size they can remain in them for several years if liquid manure is supplied while the plants are growing and the flower buds advancing. Nothing is better than occasional applications of soot water, which quickly imparts a deep colour to the foliage. Plants can be kept in small pots under the same conditions if necessary.

While growing, Gardenias require liberal applications of water both at the roots and upon the foliage, and in no stage should they be allowed to suffer from insufficient supplies. After potting water should be very carefully applied, and if the soil is moist when used some days will elapse before water is required, which will give time for the roots partially to recover from the damage received in removal.

The Gardenia is subject to many of the insects which infest stove plants, and if close attention is not paid to keep them thoroughly clean much trouble and annoyance is caused. This is, perhaps, the reason why the plants are not more largely grown in some gardens, especially where plant houses are infested with mealy bug, scale, and other insects, which at once arrest growth and leave but little chance of success in culture.

Insects of the nature indicated will not prove such a source of annoyance to cultivators if the plants are kept in good health and grown luxuriantly; but once thoroughly checked they appear to become a prey to all kinds of insect pests. When out of flower Gardenias in exuberant growth are very beautiful on account of the dark glossy foliage which is so characteristic of the plant when in good health.

In training the plants the foundation must be begun by bringing the shoots down to the rim of the pots if round bushes are required, which can afterwards be kept in shape by stopping and regulating the shoots as they grow. After flowering they can be cut into shape with the knife. The system of tying and twisting the specimens into the form of pyramids and other shapes as if clipped with a pair of shears cannot be too strongly condemned. The foliage cannot be kept clean when the shoots are closely tied and twisted together. The plants do not show off their flowers so well, nor are they so natural-looking as if grown as free informal bushes without tie or stick after the foundation has been laid.—W. BARDNEY.

### STRAWBERRY FARMING.

(Continued from page 74.)

*Planting.*—New plantations may, according to circumstances, be laid down either in autumn or early spring. Autumn planting has the advantage of yielding a partial crop the following season, but is not always practicable, owing to the difficulty frequently experienced of finding rooted runners sufficiently early and land available without missing a crop. Many soils are much subject to be raised by frost and throw out the plants, and on this account we do not recommend autumn planting later than August. The plants, then in full vigour, will thus get firmly rooted before winter. To ensure land for this planting it must either be summer-fallowed or planted with Potatoes of early sorts that may be cleared off in time.

Spring planting, on the other hand, while it yields, or rather ought to yield, no return the first season, presents no difficulty as to finding plants or vacant ground. The plants may either be left on the runners till required, or taken up the previous autumn and closely packed in beds over which ferns or straw may be thinly spread during frosty weather.

The most vigorous plants are secured from rows that are producing their first or second crop of runners, and it is well to reserve a small quarter for the special purpose of producing these. The best system of cultivation for fruiting purposes, as we shall see, makes it impossible to obtain both fruit and runners of the best quality from the same plants. We therefore recommend a small nursery of each kind wanted, to be formed the season before the plants are required. In this the fruiting stems should all be removed as they appear, and the surface lightly mulched with decayed manure and kept soft and untrodden. If the plants have room enough, say 2 feet each way, each should under this treatment produce from ten to twenty or thirty plants during the season. Beginners must of course borrow or purchase, and as strong plants carefully lifted and packed may be had in this neighbourhood at least at from 5s. to 7s. 6d. per thousand, the item is not a very serious one.

The young plants, especially in autumn, ought to be lifted very carefully by means of a fork, and the soil shaken from their roots. They should then be bunched in one hand, the roots straightened out one way and the leaves and runners the other. When a handful has been collected, all straggling leaves and runners must be trimmed off, and, if for sale, they should be tied in bunches of, say, twenty-five each. Plants thus prepared are worth a shilling or two a thousand more than if thrown carelessly together.

It is well to see that the ground is ready to receive the plants immediately they are prepared. After a well-manured Potato crop a moderate dressing of decayed manure should be ploughed in and the ground thoroughly levelled by the harrow. And now comes the question as to the mode of cultivation to be adopted. In order to avail ourselves, as far as possible, of horse labour, it is necessary to plant in rows; but while this is generally done, there are three different systems of after treatment among which to choose. First, there is the system under which such runners as may chance to root themselves in the line of the plants are allowed to remain, forming in the course of a year or two the matted row. Under the second system each pair of rows is allowed to mat together into what we may call the matted bed, alleys being thus left only between alternate rows. Under the third system, which we decidedly prefer, no runners are allowed to root at all, unless required to fill blanks. This we may call the single-stool system,

and is the only one that allows us to obtain the full advantage from the original plants. Either of the former two systems might do if we could secure freedom from weeds and a fertility of soil practically inexhaustible. It is argued on their behalf that a new set of plants is continually coming into bearing, and thus the plantation may last many years. To this we reply, that a single plant properly cultivated and kept free from runners will produce more fruit and of better quality than if allowed to spread at will; and will besides continue in full bearing for at least five or six years, by which time it is in any case desirable to break up the plantation, which we can do the less grudgingly as there are no young plants tempting us to delay till another season. The single-stool system is the only one that allows us the full capabilities of the original plants, the full advantage of horse labour, and the entire command over the weeds.

The rows should be at least 30 inches asunder, and the plants from 15 to 18 inches apart according to the vigour of the variety cultivated. At the less distance about fourteen thousand plants per acre will be required. Planting should be done by means of a line and a trowel; and if two persons are engaged—one to manage the line and make the holes, the other to set the plants—the work can be done very quickly. The roots should be spread in the holes so that each fibre may be in contact with the soil, and not matted together as is the case when a dibble is used. In autumn the roots may be planted entire, but in spring should be previously shortened about a third of their length for reasons previously given. The plants should be set so that the crowns are rather under than above the general surface; and the soil, at first filled in lightly, should be afterwards pressed so firm that it will not be easy to pull the plants up again. In very dry weather it may be necessary either to puddle the roots before planting, or to pour a little water into each hole.—WILLIAM RAITT, *Blairgowrie*.

### THE BLUE ROMAN HYACINTH

"A VERY extensive cultivator of bulbs" who condemns this form should, perhaps, give reasons for his condemnation. If on account of capricious taste in the market it is hardly fair, because that has little to do with intrinsic merit. Before reading the remarks referred to, I supposed the small favour that this form has met with to be due to shy-flowering habit. It may vary in this respect, because among a number of bulbs I have in no case less than two spikes from each, and I have even noticed three. If a blue Roman Hyacinth is of any use, I see no reason for condemning this plant. I do not see how a plant so totally distinct as *Scilla siberica* is, can be compared with it. If a lady desires bright blue flowers and does not care in the least what plant affords them, there is nothing but the *Scilla* to take. Truly the blue Roman Hyacinth is not a fine plant (nor is the white but for the acceptability of its pure white flowers), but I think that it has been condemned beyond its deserts.—L.

WE believe your correspondent in last week's Journal was under a cloud when he wrote about blue Roman Hyacinths. We have grown many hundreds of them this season, and shall grow thousands next year, they are so useful. They cannot be forced so well as white Romans, but may be easily had in flower at Christmas. The bulbs were potted in 5-inch pots, four in a pot, and treated like white Romans, each bulb producing three or four spikes, and not one missing.

The white Italian Hyacinths are also very useful, flowering about the same time, the flowers being much larger than the blue, and succeeding white Romans well.—JONES & SONS, *Shrewsbury*.

### THE VEGETABLE SUPPLY.

I CAN endorse every word Mr. Iggulden says on page 64; and I hope farmers will take the advice of a capable man like himself, and not be led astray by no doubt well-meaning M.P.'s and other gentlemen who have necessarily little or no practical knowledge of this subject, and who, in my opinion, do a great deal of harm by the advice which, through the best of motives, they give so freely.

"WILTSHIRE RECTOR" says he does not refer to London but to the provinces, when he says that the supply of vegetables is not adequate to the demand. As a provincial grower I beg to differ from him, and I say that in the markets of Liverpool, Manchester, and adjacent large towns vegetables never were more abundant or finer, neither were prices before so low as last year. Were I not afraid of taking up too much space I would specify the wholesale prices of the principal articles, prices that in most instances were a dead loss to the grower, who had to take

any price to get his cask emptied, or else take his wares home again.

The poorer classes as a rule, except the Irish who buy Cabbage, do not eat vegetables, but it is not scarcity or the price either that deters them; if they have threepence in their pocket they will purchase a pint of ale with it rather than buy wholesome vegetables with the money. The better class of working men can, and do, have a sufficient supply of fresh vegetables and fruit in their season at the lowest price at which it can be grown. Therefore in the face of these facts, and glutted markets already existing, I would advise those farmers who are thinking of turning their attention and probably some of their best land to vegetable growing, to think before it is too late, for the supply already far exceeds the demand, and the strong foreign and south country competition is every year increasing. When those growers already in the field have their land in the highest state of cultivation, with all their experience, knowledge of markets, &c., have to sell their produce for prices that barely, and in many cases do not, repay expenses, and when there are scores of acres of Savoy and other vegetables decaying on the ground for want of a demand, where is the farmer going to find his customers? In conclusion I beg most emphatically to say, and I think my fellow market gardeners will agree with me, that the supply of vegetables is already in excess of the demand, and that is not because they cannot get them at a fair price or at their own street corner that the poorer classes do not eat them. You may take a horse to the water, but you cannot make him drink.—A MARKET GARDENER, *Cheshire*.

As a subscriber to your Journal, and a market grower in the vicinity of Liverpool, permit me to add my warning against the too sanguine views of the results of growing vegetables for market. To the town of Liverpool growers take their produce in their own carts into large markets and sell direct to the shopkeepers, and are thus on favourable terms compared with some other towns. In spite of this, and also being within reach of many other large towns, I can scarcely name more than one or more vegetables that this year have paid the grower.

Cabbages, Cauliflowers, Peas, Beans, Celery, Brussels Sprouts, Potatoes, Turnips, have all been sold at prices that do not pay, or barely pay, the cost of production. Besides this, to an ordinary farmer a severe winter is no harm, to a large grower of vegetables it is invariably more or less damaging; in the last three winters, including the present, my loss is not less than £700.

The last frost in this district was disastrous. Savoy and Brussels Sprouts are nearly all killed, and besides Celery will be a serious loss.—A MARKET GARDENER, *Liverpool*.

#### THE GREAT FROST.

"BLACK TUESDAY," says the *Times* (January 18th, 1881), will long be remembered by Londoners. I do not think we here, in the valley of the Mole, shall soon forget the last half of the present month. Old inhabitants tell me they remember nothing like it since Murphy's frost. I can answer for no such weather here for nearly twenty-two years. We have, I believe, in this part of Surrey the unenviable notoriety of having recorded (through Mr. Steward of the Strand) greater cold than any other part of the south-east. It may be interesting to others to hear of our misfortunes. As a Latin poet has said, "*Suave mari magno*," &c.

"Sweet to see tossings on the sea,  
While we on land all safe may be;  
Not to delight in others' pain,  
But since escape is so much gain."

The happy inhabitants of warmer regions will endorse this when they read of 30°, 32°, and 33½° below freezing which I registered on the mornings of January 17th, 22nd, and 25th. We are about 200 feet above the sea, and my thermometer is a maximum and minimum of Mr. Steward's on a sheltered stand 4 feet above the grass. My readings are borne out by those of a neighbour on the opposite bank of the Mole. It is difficult to account for such extremes of cold, but low readings appear to follow the course of this river. Mr. Mawley of Croydon, a high authority in such matters, suggests "the cold air rolling down at night from the hills (the North Downs just above us) into the valley" later in the spring. I may have something to say if space is afforded me as to how the Roses have stood it, standards having had no protection. At present there is a little varied prospect of blacked branches, and plants apparently dead down to the snow line.—A. C.

GISHURSTINE.—You did me the favour to publish (page 65) the report of a very high professional gardening authority of his experiments with Gishurstine to keep boots dry. I have just

received an excellent opinion from an amateur—the well-known authoress, Miss Frances Power Cobbe—and shall be much obliged if you will give it space. Miss Cobbe writes: "To-day I sallied forth over swamps and morasses in Wisley Common for hours; and here I testify that though my boots were already rather worn, and last week decidedly let in damp, I have returned this evening with my feet warm and dry, as if I had never stepped but upon a wooden floor. Gishurstine is admirable."—THE INVENTOR OF GISHURST COMPOUND.

#### COMPARETTIAS.

THERE are now numbers of beautiful winter-flowering Orchids in cultivation, and with a moderately extensive collection little difficulty is experienced in maintaining a bright and satisfactory

Fig. 23.—*Comparettia falcata*.

display in the structures devoted to such plants. The small genus now under notice is well known to many Orchid growers; and though the few species it includes are not entitled to rank among the most showy of their order, they possess several recommendations. The racemes are elegant, generally drooping, and bearing small but brightly coloured flowers that are produced in the latter months of the year, or from January to March. The plants are all epiphytal in habit, succeeding well on small blocks of wood suspended from the roof of a moderately warm house, but not where they are too fully exposed to the sun. In other respects the treatment they require is similar to that of most tropical epiphytal Orchids.

*Comparettia falcata*, the species represented in fig. 23, is one of the best known, and is seen in most metropolitan nurseries and in the chief collections of Orchids in the country. It produces a rather loose raceme of deep rose or crimson-coloured flowers from the base of the pseudobulbs, the scape usually being much longer than is shown in the cut, the flowers being borne near the

extremity. The labellum is the chief distinctive feature of the flower, it being strangely restricted in the middle. *C. rosea* is another pretty species with shorter and more compact racemes than that mentioned above, but it is much more rarely seen. *C. coccinea*, which has pale scarlet tinted flowers, is very attractive and free in flowering, particularly handsome specimens being occasionally met with.—R. L.

#### EARLY TOMATOES.

WHERE Tomatoes are held in high esteem—and they are annually gaining favour—they, like most other choice vegetables, are much valued early in the season. Last year we cut fruit from our spring-raised plants in April, and by the end of May we had abundance. At that time Mr. Godwin from Messrs. Dickson, Chester, and other visitors told me they had never seen finer crops of Tomatoes in pots, and they were sure this system of growing them was well worth being generally adopted. The plants which were so well in fruit then were raised from seed Mr. Coleman of Eastnor very kindly sent me to try, and a finer variety I have never seen. It might be described as an extra good variety of Trophy, but so much superior to the many "varieties" of that now out under different names that the public would certainly be the gainers were it sent out as an improved variety.

To have Tomato plants in fruit in April no time should now be allowed to pass before sowing the seeds. These are best placed in 3-inch pots. After filling the desired number of these with any rich soil two seeds should be placed on the surface in each and slightly covered. If the pots can then be plunged in a gentle bottom heat the plants will appear all the quicker, and then they should not be placed far from the glass, as drawn spindly plants are never so good as short-jointed robust ones, and all depends on the position in which they are grown. As soon as the plants are 2 or 3 inches high the weaker of the two should be drawn out. If plants are scarce pot this on, but do not neglect the one left in the pot, as it will make the best and earliest fruiting plant. When it is from 6 to 8 inches high it should be transferred to the fruiting pot. This may be either 8-inch or 10-inch size. For small corners the former may be used; where space is abundant the larger size is better. The fruiting pots must be well drained, and the soil employed must be good. Loam and cow dung are suitable, and these must be used in a rather dry state. The soil must be rendered firm, or the roots soon take possession of it, and they are liable to receive a check at any time from deficient supplies of water. They do not need bottom heat after being placed in the fruiting pots, but if they can be arranged on a shelf in an early vinery, Pine house, or plant stove where the heat is between 60° and 70° they will grow rapidly and soon make fine plants.

When they are about 1 foot high a stake 3 feet long is placed to each, and the stems are tied to this. When the plants are grown robustly they will show bloom by the time they are a foot high, and clusters of flowers will appear every few inches after this. Numbers of fruits will form on each of these, and by the time the plants are at the top of the stakes eighteen, twenty, or more fruit will be formed on each. This number is a good crop to begin with, and the point should be taken from each plant at this height, all side shoots removed, and little or no growth be allowed to be made until the fruits are swelling. At this time plenty of water and liquid manure must be given, and a side growth may be allowed to form occasionally to produce a bunch of bloom and fruit in succession.

As they grow quickly and may be trained any way, or cut-in to any extent without injury, it is an easy matter to cut all barren wood out and only leave that which will bear fruit. When the first leading growth has fruited and become exhausted a fresh one may be taken up from the bottom and be treated in the same way as the first until it comes into bearing, when the old one may be cut away. When this is done a good top-dressing should be given to assist the young growth. There is no secret in fruiting Tomatoes early, nor does it require a great amount of skill, if they are only grown in pots in a warm position near the glass and never allowed to carry more wood than what is bearing the fruit.—J. MUIR.

#### ROYAL HORTICULTURAL SOCIETY.

THE annual general meeting of the Society was held in the Council Room, South Kensington, at 3 P.M. on Tuesday, the 8th inst., the President of the Society, Lord Aberdare, in the chair. The following members of the Council were present:—Sir Trevor Lawrence, Bart., Major F. Mason, Sir Charles W. Strickland, Bart., Henry Webb, Esq. (Treasurer), Dr. Hogg (Secretary), Rev. Harpur Crewe, Dr. Denny, and William Haughton, Esq. There was a moderate attendance of members.

The proceedings commenced by Dr. Hogg reading the minutes of the last annual general meeting, and he also announced the names of twenty-eight ladies and gentlemen desirous of becoming Fellows of the Society, who were formally elected by a show of hands. It was announced that there were three retiring members of the Council—namely, Sir Henry Scudamore Stanhope, Bart., Lord Sudeley, and H. J. Elwes, Esq., and the Fellows recommended to fill the vacancies thus caused were J. T. D. Llewellyn, Esq., James McIntosh, Esq., and George F. Wilson, Esq.; Mr. John Lee and Mr. James F. West being appointed scrutineers of the ballot.

LORD ABERDARE then proceeded to briefly review the position and prospects of the Society, commenting on the serious effects unfavourable seasons had in recent years produced in the diminution of receipts, so that careful thought and attention had been rendered necessary to balance their accounts in a satisfactory manner. He then referred to the scientific portion of the Society's work, which he said some thought had been neglected, and it was owing to a desire to impart additional scientific interest to the fortnightly or monthly meetings of the Committees that the Rev. G. Henslow had been engaged to deliver a lecture on each occasion concerning the plants exhibited. These had given considerable satisfaction, and had been generally well attended, the lecturer having conveyed much useful instruction in an easy and intelligible manner. The President then stated that to gain an adequate idea of the advance made by the Society during the past year it would be necessary to compare the financial position of the Society in the two previous years with that of 1880. He referred to the chief causes which had reduced the receipts—namely, the exhibitions held by the Royal Botanic Society and at the Crystal Palace, the former internal dissensions of the Society, the falling-off of the Fellows, and in some degree the general depression of trade. But there were now better prospects, for one very healthy sign was the great increase in the number of Fellows. In 1878 £6101 were expended, and the receipts fell short of this by £162. In 1879 the expenditure was increased, on the theory that if you do not sow you cannot expect to reap; but the result was not encouraging, for while the expenditure amounted to £7198, only £6542 were received. In 1880, however, they had felt bound to reduce their expenses in every possible way, although it was admitted that the exhibitions and meetings had been even finer than usual, notwithstanding the unfavourable weather. The income for the past year was £6820, and the expenses £6943, being a balance against the Society of £123, which was due to legal expenses incurred in the Chancery suit. This he considered a steady advance, as was apparent from the facts he had already stated. In commenting upon the prospects of the case in Chancery, he remarked that the debenture holders were now admitted as defendants; and though there was still considerable uncertainty as to when it would be settled, he trusted that the decision would prove fair and satisfactory to all concerned. He considered the outlook of the Society encouraging, and although some considered the Society doomed, he thought it might be safely described as—

"Oft doomed to death, but fated not to die."

He then moved the adoption of the report, which was seconded by Mr. John Lee, and carried unanimously.

On the motion of Mr. William Haughton, duly seconded and carried unanimously, a Fellow of the Society sentenced to five years' penal servitude in 1876, and now at liberty, was expelled the Society, he having refused to retire. It was then stated that the officers and proposed members of the Council had been elected, and the meeting concluded with a unanimous vote of thanks to Lord Aberdare.

#### REPORT OF THE COUNCIL TO THE ANNUAL GENERAL MEETING OF FEBRUARY THE 8TH, 1881.

THE Council congratulate the Fellows on the steady improvement of the Society during the past year. The number of Fellows and the receipts from all sources have increased.

The efficiency of the Chiswick Garden has been maintained during the past year, and an increasing interest is taken by the Fellows and visitors in the work that is carried on there.

Under the direction of the Fruit and Floral Committees the experiments in the garden at Chiswick have been conducted with favourable results, which have been received by horticulturists both at home and abroad with the interest and approval which attach to the scientific operations of the Society. In the vegetable department collections of Aubergines, Capsicums, Brussels Sprouts, and Parsnips have been grown, and the examination of them enabled the Committees to correct erroneous nomenclature and to discard any varieties that are worthless, while those of superior merit have been brought into prominence. Collections of Pelargoniums, Fuchsias, Gloxinias, Begonias, Pompon Dahlias, and a number of miscellaneous plants have also been examined. For some time past special attention has been given to the varieties of tuberous-rooted Begonias as decorative plants; and Mr. Barron, the Garden Superintendent, has succeeded in producing a number of varieties, which have created much interest and been greatly admired. Ten of the seedlings raised by him have received first-class certificates.

The Society now possesses, perhaps, the most extensive and complete collection of the species and hybrid forms of the genus Pelargonium that is to be found in this country, and these interesting plants have been objects of admiration and curiosity to a large number of visitors to the garden and the exhibitions.

A desire has been shown by the inhabitants of the neighbourhood of Chiswick Garden for the resumption of flower shows there. During the past year a local organisation was formed, which received the support of the Council, and a very successful exhibition of flowers was held for the benefit of the West London Hospital, the garden being thrown open to the visitors. The profit derived from this Exhibition realised upwards of £80, which was handed over to the hospital. It is in contemplation to hold another exhibition this year, and a similar organisation has been formed to carry out the arrangements, the object being to encourage the horticulture of the district and to strengthen the Society.

Some rearrangement of the garden has been deemed necessary, and a considerable portion which was formerly occupied with bedding plants has been converted into a broad lawn.

The crops of outdoor fruit are very short, the trees not having recovered from the injuries of the disastrous season of 1879. Peaches on the open walls were very scarce. Pears were more numerous and generally of good quality, but the crop of Grapes in the large conservatory was not so good as in previous years. The Vines in the long glass wall, which were planted two years ago, have been a great source of attraction from the luxuriance of their growth and the high development of their fruit, which illustrate the excellence of Gros Colman and Alicante as late varieties.

It being deemed advisable to discontinue the cultivation of orchard-trees, the system having been thoroughly tested and established, it is proposed to plant the large orchard house with a collection of Tea Roses, and the Council will be happy to receive any contributions in plants which the Fellows may wish to make towards this object.

The sales of garden produce during the past year amounted to £641 1s. 10d., being £17 in excess of last year, and the total receipts of Chiswick Garden amounted to £709 4s. 1d., being nearly £100 in excess of last year.

The distribution of plants and seeds to Fellows far exceeded that of any previous year; 1,020 Fellows were supplied with 19,622 plants and 8,424 packets of cuttings of fruit trees, and 40,559 packets of seeds.

The Society is indebted to many of the Fellows for liberal donations of seeds and plants to the garden, among whom are J. T. D. Macintosh, Esq., Col. R. Trevor Clarke, H. H. Gibbs, Esq., Sir Charles Strickland, Bart., G. T. Clark, Esq., Sir Bartle Frere, Dr. Regel of St. Petersburg, for bulbs and hardy plants; Mr. Herbst of Richmond, for three hundred Palms for distribution; Sir George Macleay, Baron Mueller, &c.

At South Kensington the fortnightly and monthly meetings of the Scientific, Fruit, and Floral Committees have been well attended, and the lectures which have been delivered by the Rev. George Henslow at the general meetings have been most attractive and have given great satisfaction.

The Great Summer Show, which extended over four days, was one of the finest ever held in the garden, and but for the wet weather on the first two days it would have proved financially a great success. The special thanks of the Society are due to the exhibitors, and especially to the leading nurserymen, for their never-failing support of the Society.

The Auricula Society's Exhibition in April was very well attended, and excited great interest.

The Society's Rose Show and the Pelargonium Society's Show were held in conjunction, and were in every respect a success, the Show of Pelargoniums being the best hitherto held.

The Carnation and Picotee Society's Show and the Exhibition of the British Bee-keepers' Association, which were held simultaneously, attracted many visitors. Besides these there were Exhibitions on Whit-Monday and on the Bank Holiday in August. The former, for flowers grown specially for Covent Garden Market, was visited by upwards of 19,000 persons; and the latter, for flowers grown by artisans and cottagers, was attended by 11,370. The Council, being desirous of fostering and encouraging the love of flowers among the masses, have made arrangements to continue the Great Summer Show this year over Whit-Monday and Whit-Tuesday.

The conversazione held on the 26th of May, and the evening fête on the 21st of July, were numerously attended, and gave great satisfaction to the Fellows and visitors.

The garden at South Kensington has been maintained in the highest state of keeping which the means of the Society allowed. Some of the larger trees, which were overcrowding those of greater value, have been removed, and a greater extent of grass lawn has been obtained. The Council trust that the returning prosperity of the Society will enable them to make it still more attractive.

The game of lawn-tennis has become very popular in the garden, and every facility is afforded to the Fellows and their friends to indulge in that healthful exercise.

The action between Her Majesty's Commissioners and the Society is still pending in consequence of the opposition of the plaintiffs, the Commissioners, to the debenture holders being made parties to it. The Court of Appeal, to which the plaintiffs carried the point, unanimously decided against their contention that the debenture holders had no right to be heard, and ordered Mr. Percival De Castro as their representative to be added as a defendant. This decision gave Mr. De Castro the right, of which he has availed himself, to counterclaim against the plaintiffs, and all questions between the Commissioners, the Society, and the debenture holders can now be decided.

As was last year explained to the Fellows, the presence before the

Court of the debenture holders was absolutely necessary to relieve the Society from the grave risk which it would have incurred if it had voluntarily surrendered the South Kensington Gardens, or left it open to the debenture holders to contend hereafter that it had not raised in the action every defence open to it, and so occasioned the destruction of their security. The Council have no reason to anticipate further delay in the proceedings, and hope the case will come on for hearing soon after the return of Mr. Justice Fry from circuit.

During the past year 238 free monthly tickets have been issued to students in the Science and Art Schools, with permission to sketch in the gardens and conservatory.

The Society has lost during the past year 29 life Fellows and 32 annual Fellows by death, and 82 by resignation. 207 new Fellows have been elected during the year.

The roll of Fellows now consists of—

808 life Fellows.  
435 Fellows paying £4 4s. annually.  
860 " " £2 2s. "

2103

The number of members paying one guinea annually is 87.

### COTTAGE GARDENING.

RIPE fruit is most wholesome food, as pleasant to the taste as it is nourishing, and well would it be if it were more often seen upon the poor man's table. Some years ago I had occasion to consult a London physician about the state of my health; he questioned me closely about my diet, and strongly advised me to take more vegetables and fruit than I had been accustomed to. "If possible," said he, "always let stewed fruit and rice form part of your dinner." Now that is a dish frequently seen upon the tables of the rich, and yet it is emphatically a poor man's fare if cost be any guide in such matters, for the rice and sugar required for a large dish need not cost more than 2d. The fruit should of course be obtained from the garden, and among such fruit the Strawberry ought certainly to hold a leading place, for its culture is easy, its crop certain and abundant, and it can be as well grown along the sides of the garden paths and under the partial shade of trees as if it were out in the middle of the garden. Only treat it well and it will repay all your pains. Dig the soil deeply, mixing plenty of dung in it. Obtain young plants in August if possible, plant them 1 foot apart in the rows, and if you can spare space for a bed let the rows be 2 feet apart. Give them plenty of water, or better still soapsuds and slops from the cottage; keep down weeds, cut off all runners as soon as they appear, and your plants will grow so freely and become so strong that you will have a good crop of fruit in ten or eleven months from the time of planting. But, remember, if you delay planting till the autumn you will have no fruit next season, and in any case a full crop cannot be obtained till the second season. After the fourth season the plants should be destroyed as soon as the fruit is picked, and young plants again employed. So, in order to keep up a full supply of fruit, it will be well to have two beds or two rows, replanting one every second year; for although old plants will continue to bear fruit for many years, yet it comes smaller, some of the plants die, and the rows gradually appear as ragged as they are unprofitable. You may continue replacing old plants with young ones for a lifetime provided you enrich the soil regularly with plenty of dung. The best variety for a cottage garden is Garibaldi, better known among gardeners as Vicomtesse Héricart de Thury; but that is much too long a name for us, and I may tell my cottage friends that I have known many excellent gardeners who could grow it well and yet were quite unable to pronounce the long French name, so we may very well be excused from attempting it. Another excellent sort, a great favourite of mine, is Marguerite, having very large fruit in great abundance; and if you desire a variety to win prizes with, plant a dozen or two of Cockscorn, and its fruit will astonish you and save the time of the judges at your flower show, for what can they do but ticket its great fruit with "First Prize?"

Raspberries are much more common in cottage gardens, but the varieties grown are often inferior. I can strongly recommend Prince of Wales for its long stout canes and heavy crops of large red fruit. Unlike Strawberries, Raspberries if well planted and well cared for continue bearing in full perfection for many

years. Be sure and stir the ground two spits deep, making it as rich as you can with dung and road scrapings. One now will be enough. Plant in November strong canes shortened to 2 feet. Do not dig among the roots in after years, but lay a little dung upon the soil above the roots, and pour soapsuds or sewage over it as often as you can in summer while the fruit and canes are growing.

Plant Gooseberries as near the cottage as you can to keep bullfinches from pecking out the buds in early spring. It is well not to prune them till you see if the buds are safe, which they will be when they are just bursting in spring. If you are not troubled by these birds by all means prune early, for late pruning is apt to weaken the bushes. I have grown a great many sorts of Gooseberry, and think the best two for our purpose are Early Sulphur and Red Warrington, both good croppers of excellent flavour, with medium-size fruit. Warrington is especially valuable for preserving.

Of Currants, Knight's Large Red and Red Dutch are the best of that colour; White Dutch among whites; and Lee's Prolific Black, a new variety as much superior to older sorts. Currants do not thrive in a poor thin soil, and are not a profitable fruit for a cottager unless he can give them a deep rich soil: when that can be done no fruit is more profitable, especially the Black Currant.

Most old cottage gardens contain a Quince tree, and of other fruits there should be a Cluster Damson, Rivers' Early, and Victoria Plums; and if Cherries are planted take May Duke and Kentish.

All the varieties of fruit I have named and chosen from a large collection, and may be relied upon as suitable for most gardens. It is always well to grow really good fruits, especially in small gardens, where every foot of space should be turned to good account. To those of my cottage friends who may feel puzzled how to procure them, I may very confidently say that most gentlemen will very gladly encourage such a praiseworthy effort by giving them surplus cuttings or plants. Better still if they are obtained by the exercise of a little self-denial and thrift. Plants of bush fruits and Strawberries only cost a few pence each, fruit trees a shilling or two. The latter are, however, often raised by the cottager himself. I know a man who has an acre of Apple trees, every one of which he raised by sowing Apple pips for stocks and grafting them with good varieties.—EDWARD LUCKHURST.

### CUTTING DOWN YOUNG VINES AND PEACH TREES.

ALMOST all amateurs in commencing Vine culture wish their young Vines to come into full bearing as soon as possible. Opinions differ as to the best way of doing this; different systems have been and are being followed to compass this end. I remember hearing of an amateur in Hertfordshire some thirty years ago cutting down his young Vines to the ground for four years in succession, and thus obtaining stronger rods or canes every season till his houses were filled with vigorous Vines. The results were highly satisfactory, and his crops of Grapes were second to none in England at the time. Another large grower of Grapes in Cheshire does not cut down young Vines once. On planting them he ties the trailing canes up to the full length of the rafters and allows them to remain so. Men of experience would naturally condemn the practice of this Cheshire grower. Well, what has been the result? Two houses 60 or 80 feet long were planted with Muscats, and a third house the same length was planted with Black Hamburgs. In the first season the Vines broke at the tops of the canes only, and 6 or 7 feet from the ground up remained naked and shootless for twelve months. The shoots at the tops of the Vines in the Black Hamburg house carried and ripened large bunches of good Grapes. The Muscats did not bear well the first season. All the Vines were planted in very rich borders composed of manure and decaying vegetable matter. Second season the Vines broke well from top to bottom, and made excellent wood and bore some fruit. Third season full crops of good Grapes. Yesterday I walked through the houses and found the Vines looking well, and the Black Hamburg Vines were in leaf, with a good show of fruit already visible. This Cheshire grower has in an unorthodox fashion succeeded capitally. His rich border did more for his Vines than his skill in growing them.

I think there is a better method of filling houses with good Vines than either plan now noticed. The common practice of cutting young Vines down to the ground on being planted cannot be too strongly recommended, and if they are planted 4 feet asunder one shoot only should be taken from each Vine, retaining no fruit the first season. Cutting the Vines down to the ground a second time is doubtless a waste of power; cutting them down to midrafter is better, so that every bud will produce a shoot.

The shoots of these young Vines generally show fruit, and are capable of bearing it. Is it wise to let them bear? In order to have a house full of strong fruit-bearing canes I think no fruit should be taken the second season, that all the bunches of flowers should be removed as soon as seen, and the shoots left to give strength and constitution to the Vines. This is much better than cutting back the Vines to the ground a second time. The main shoots have to run from midrafter to the top only, where they are stopped, and then they send out lateral shoots, which assist the Vines; thus, by the end of the second season from planting houses are filled with excellent rods capable of bearing full crops of Grapes from bottom to top on the third year from time of planting; of course it is possible to take half a crop of good Grapes off Vines the second year from planting, but it cannot be done without checking the growth and development of the Vines.

The practice of cutting down young trained Peach and Nectarine trees—so common forty years ago—has been abandoned long ago by thoughtful men. The object aimed at in cutting down the young trees was to obtain plenty of shoots to begin with. Peach trees, like Gooseberry bushes, break at every bud, and therefore have to be disbudded from the first. Cutting down Peach trees, to say the least, is not good practice; generally speaking a season is lost and often harm is done as well, for young Peach trees are apt to produce shoots rather too strong on being planted in fresh soil. A rich border so good for young Vines does not answer well for young Peach trees.—A. PETTIGREW.

#### SOLDAT LABOUREUR PEAR.

"SOLDAT LABOUREUR I think well of; its growths are Poplar-

Fig. 24.—PEAR SOLDAT LABOUREUR.

like and pleasing, it does not canker, it fruits regularly, and with artificial heat it ripens well." Thus wrote "WILTSHIRE RECTOR" in our last volume, and his remarks were, if brief, sufficiently commendatory to lead to inquiries respecting the variety. We answer them by publishing the annexed engraving and description of the fruit. One correspondent has not comprehended the meaning of "WILTSHIRE RECTOR'S" reference to the fruit "ripening well with artificial heat." It simply means that the fruit, if removed from a cold fruit room into a warmer temperature, is of better quality than if left to ripen in a cold place—a plan we know to be an excellent one and worthy of extensive adoption. The description of this clean-growing and good Pear is as follows:—Fruit large,  $3\frac{3}{4}$  inches long and 3 inches wide, oblong obovate, narrowing from the bulge both towards the eye and the stalk. Skin pale lemon yellow, marked here and there with tracings of russet, and completely covered with minute russet dots. Eye large, slightly closed, with long acuminate segments, and placed in a shallow depression. Stalk an inch long, inserted by the side

of a fleshy swelling in a narrow cavity. Flesh yellowish white, buttery, melting, and very juicy, rich, and sugary, having somewhat of the flavour of the Autumn Bergamot.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 18. NEW SERIES.

STRONGLY as the horticulturist may feel inclined to object to weather of such severity as that which has prevailed during the greater part of the past month, he would regard it with less dislike if he knew it was generally destructive to insect foes of the garden. Accurate and extended observation proves that extreme cold is not as harmful to insects as we might suppose. Other creatures—quadrupeds and birds, for example—suffer much, but insects appear to endure low temperatures better than moisture. Caterpillars of those species that hibernate in that condition have been picked up in frosty weather so rigid as to chink against glass like pebbles, and yet they have afterwards

revived. It is in the egg and the larva stages that insects pass through the winter most successfully; pupæ are apt to die from a variety of causes, so are the perfect insects that live from autumn to spring. The beetles that we have been recently considering, and especially the weevils, are a sturdy race, yet there are differences. Doubtless when there are two species of similar size and habits, and one is rare while the other is abundant, it may be conjectured that the scarce species is either more delicate or specially attacked by parasitic enemies.

Of these weevils already several thousand species have been fully made out, though our British species are limited to a few hundreds. We at once recognise them by the extension of the head into a snout, and by the antennæ set in front. Some species are minus wings, the majority possessing them are slow flyers. Nearly all have the habit of falling readily when alarmed from any substance they are eating or crawling upon. Most of the larvæ are hidden feeders, doing a greater amount of mischief than the mature beetles. White and fleshy grubs, legless, and with small heads, we might think them harmless were it not for evidence to the contrary, proving how effective is the action of their muscular and trenchant jaws. The weevils are subdivided into two groups; the first has straight antennæ, the second has them elbowed or bent.

Proceeding to examine some of the species in this family we commence at the genus *Bruchus*, of which we have eight native species. It is a speculation of several naturalists that none of these are truly British, but that they were introduced with foreign corn, Peas, and Beans; if so, they have now become quite at home in these islands. Every gardener and most cooks know too well the larva of the Pea weevil (*B. Pisi*), and as, in the general way, each one consumes but a single Pea, we can fancy how numerous they must be in cases where a whole crop has been ruined by them. The little brown and white beetles are about a tenth of an inch in length, so that, though it has been recommended to look out for them at the flowers to which they resort in the summer, this is not easy of accomplishment. As, however, the larvæ turn to pupæ in the pods, we have them at our mercy towards the autumn, when it is sometimes necessary to burn whole rows that have been infested. *B. granarius* is another very familiar species, darker than the preceding, but similar in size; this species visits both Peas and Beans, and unfortunately does some injury to the dried seeds as well as to the fresh crop, its vitality being strong. All Leguminous plants are liable to the attacks of one or other of the *Bruchi*, nor do they limit themselves to the species supplying us with food. The larger species called *B. villosus* comes out early in the year, and seeks the golden bloom of the Furze, placing its eggs amongst the young seeds just as they are forming. The result is, that instead of seeds there is to be found only heaps of frass, and more beetles come out to renew the attack during the autumn. Abroad there is found a *Bruchus* bold enough to attack such a large fruit as the Cocoa-nut. Still less in size than the insects of the genus *Bruchus* are those belonging to *Apion*, of which we have several score of British species. From the shape of the tiny body resembling that of a Pear has arisen the name they bear. Their limbs are so slender that the naked eye can hardly perceive them. The Clover is infested not merely by one, but by numerous species of the genus, especially by *A. flavipes* and *Trifolii*, and by means of a net swarms of these may be swept off this plant when it is in flower. They may also be found plentifully upon the flowers in hedge-rows near Clover fields, to which they convey themselves by means of their legs, for their elytra enclose no wings. In some seasons these weevils affect noticeably the due development of the seeds. Others of the genus have been discovered in Peas and Beans, operating upon these as do the *Bruchi*. A few bore into the roots or stems of plants, such as *Apion radiolum*, a foe to the Hollyhock, the proceedings of which explain unpleasantly to the gardener why some of his choice plants decline. This beetle, which is of a deep green, almost black colour, insidiously pierces holes here and there in the stems of Hollyhocks, within each of which holes an egg is placed. The larva feeds upon the pith, and then turns to pupa in its hiding place. One of the largest *Apions* is *A. carduorum*, about a sixth of an inch long, with steely green elytra, and a frequenter of Thistles.

From these we proceed to a very distinct family called the *Brachyderidae*, from the circumstance that the broad head is set close upon the thorax, making them short-necked. We are still amongst the enemies of the Peas, for *Sitones lineatus* the Striped Pea Weevil, attacks the young leaves of the plant at the very period when it can least bear injury from insects, having enough to do to sustain itself in our usually ungenial spring. The beetles, emerging in autumn, hide during winter where they best can, and re-appear as soon as the Peas are ready for them. The

small jaws of the beetles leave conspicuous traces upon the leaves, while their nocturnal habits are much in their favour; but they have other enemies than man. Our Scotch friends, with a freak of imagination, name the species the cuddly or donkey from its grey hue and its protruding ear-like antennæ. By a singular eccentricity of habit some of the weevils in this family form cocoons of open threads of silk, within which the pupa reposes. These are chiefly in the genus *Cionus*, and the larvæ occur on the leaves of the Mullein and plants of the natural order to which that belongs.

It might be said of the species in the genus *Cionus*, that they are, like one or two *Apions*, in some degree useful, since their operations have a tendency to check the increase of Thistles. Almost the biggest of our weevils is *C. nebulosus*, approaching an inch in length, the elytra have ashen-grey scales which are easily rubbed off, thereby altering the appearance of the markings. It is rather scarce; but a commoner species, *C. suleirostris*, has been perceived to kill Thistles just before the period of flowering, the larva burrowing in the root, or lower part of the stem. One of the species, however, *C. Linariæ*, has, however, occasionally been taken in gardens, preying upon various *Antirrhinums*.

We close this article with a brief reference to the genus *Phyllobius*, containing species which infest fruit trees. Here again the damage is done by the beetle, not the larva. *Phyllobius oblongus* is a long-bodied slim beetle, reddish brown, and having long antennæ. May is their season of activity, when they visit the young leaves of the Apple by preference, though they are also seen at times upon the Apricot, Peach, and Plum. Another species, *P. Pyri*, is more attached to the Pear, the leaves of which it bites during April; this is similar to the preceding, but of a dark brown. These weevils are not excessively troublesome, yet when they have located themselves in an orchard it is almost impossible to entirely destroy them.—J. R. S. C.

## NOTES AND GLEANINGS.

At the Annual General Meeting of the Royal Horticultural Society held at South Kensington on Tuesday last, the Right Hon. Lord Aberdare in the chair, the following candidates were duly elected Fellows—viz., John Capron Bigg, Douglas Brown, Miss Emily Bunbury, Major Ellis, James Charter, Joseph Cheal, J. J. T. Somers Cocks, Mrs. W. J. R. Cotton, Lady Dennison, Rev. J. F. Fitzwygram, Mrs. James Foster, Mrs. Gardiner, Mrs. Hamlin, Mrs. Le Champion, Joseph Little, Mrs. Charles Mercer, Louis Nathan, J. C. Nelson, Arthur Parson, Amos J. Perry, Benjamin Piercy, Henry Potter, Major W. Salmond, Octavius Toogood, Mrs. B. G. Wilkinson, J. R. Worcester, Miss A. M. Worcester, and Colonel J. Copley Wray.

— A MARKET GARDENER writing upon PITHY CELERY says, "I save own seed and select it most carefully, as it is difficult to purchase good seed. I grow two or three acres of Celery, and no matter how dry the season I never see a hollow stick and rarely a short one, and yet for market growers to attempt to supply water would be absurd. Three things are needful—a good variety, plenty of decayed manure, and good cultivation."

— REFERRING to our illustration of *IMANTOPHYLLUM CONCINNUM* in last issue, a correspondent writes—"There is no doubt an important future for it and its allies. Some of the Ghent nurseries have raised a great variety from seeds; at Van Geert's in particular we saw quantities of young hybrid plants, many of which had been flowered, and from their splendid character any ordinary price had been refused."

— "J. L." sends us a report of the FROST IN LEICESTERSHIRE, in which we observe that the lowest temperature registered was  $2\frac{1}{2}^{\circ}$  below zero on the 15th ult. He also states that although *Maréchal Niels* and other Roses were all covered with mats, he fears by their appearance that they will be cut down to the ground again. Cabbages are all killed and many of the Broccoli.

— WE are informed that a meeting of the Executive Committee of the REIGATE ROSE ASSOCIATION was recently held at the house of the active President, G. Baker, Esq., when it was determined to recommend that the annual Show be held at Reigate on Tuesday, July 5th, 1881.

— "W. J. M." writes—"Will some of your correspondents state how their OUTDOOR VERONICAS fared during the late frost, such as *V. Hulkeana*, *V. decussata*, *V. salicifolia*, and *V. pinguifolia*, as I am collecting information in reference to nominally hardy, half-hardy, and tender shrubs that are usually grown in open borders?"

— ONE of the grandest displays of PHALÆNOPSIS SCHILLERIANA that has ever been produced in this country may now be seen in the nursery of Messrs. J. Veitch & Sons at Chelsea. When it is stated that there are nearly five hundred flowering spikes and quite eighteen hundred expanded flowers in one house, some idea may be formed of the striking and charming effect produced. The plants are mostly small, having only been imported last year, and they are grown in small pots, saucers, and baskets, some on the stages, and others suspended from the roof. The foliage is as fine in its way as the flowers, and the healthy rope-like roots are such as Orchid growers delight to see. Both as a floral spectacle of extreme richness and as an example of superior culture the collection is alike remarkable, and is certainly worth a long journey to witness. There is a great difference in the tints of the varieties, some being extremely soft and others rich, while many of the blooms are of great size and substance, and altogether the display is magnificent and unique. The plants will remain in beauty for another week or ten days, fogs permitting.

— IN another house in the nursery we were fortunate in seeing one of the finest NEW CALANTHE that has ever come under our notice—*C. Sandhurstiana*. This was raised and grown by P. H. Gosse, Esq., F.R.S., of Sandhurst, Torquay. It was the result of a cross between *Limatodes rosea* and *Calanthe vestita*. One of the spikes contained nearly fifty flowers, but they were so closely set on the stem and all round it that it was difficult to count them. The prevailing colour of the richer form was rich rosy crimson, the others being a few shades lighter. Mr. Gosse has been fortunate in adding a variety of such striking merit to this valuable genus of terrestrial Orchids.

— THE increased and growing EXPORT APPLE TRADE IN AMERICA has, says the "American Cultivator," been larger than ever before, amounting to 425,000 barrels in 1880, against 176,000 barrels for the previous year. The bulk of the Apples exported have been of the Baldwin variety, and many of them have come from New Hampshire, where the crop was especially large and of excellent quality last season. Some farmers in that State have realised handsome sums from their Apple orchards.

— MR. ALEXANDER ANGUS, who for the last four years has been foreman in the fruit department of the Royal Horticultural Society's Gardens, Chiswick, has been appointed gardener to Chas. H. Wilson, Esq., M.P., Warton Priory, Pocklington, Yorkshire; and Mr. ROBERT CASTLE, late gardener at Derwent Lodge, Kensington, has succeeded Mr. W. Iggulden as gardener to Captain Wingfield, Orsett Hall, Romford, Essex. MR. ORCHARD, late gardener to F. W. Harris, Esq., Coombe House, Croydon, has been appointed gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston-on-Thames.

— IN the Orchid house at Kew may be seen a very fine example of DENDROCHILUM GLUMACEUM. It is now making a fresh set of pseudo-bulbs, and each growth or pseudo-bulb bears a beautiful arched spike of flowers—altogether no less than

fifty-two spikes. The individual flowers are not very showy, but when all are fully expanded the plant is very elegant. The colour of the flowers are creamy white, but what they lack in colour is more than balanced by the delicious spicy perfume they exhale. The flowers last at least three weeks in good condition, thus rendering the plant very desirable. It thrives well at Kew potted in fibry peat and sphagnum moss.

— SIR ROBERT CHRISTISON, BART., recently read a paper before the Edinburgh Botanical Society on THE GROWTH OF WOOD IN 1880, which contained a description of several interesting observations. It appears that the growth was even less than in 1879, deciduous trees, except Oaks, being most affected, and evergreen Conifers least. The small extent to which the growth of Oaks, particularly the Hungary Oak, had been influenced, was stated to be very remarkable. In some further observations upon the season of growth in trees, it was remarked that with fine deciduous trees in fine seasons the growth of wood was nearly confined to the months of June, July, August, while the same number of evergreen Conifers commenced growth a month earlier, but concluded it about the same period.

— MR. WALTER HILL, Director of the Brisbane Botanic Garden, writes as follows upon the uses of the CASUARINAS or Beefwoods of Australia:—"Casuarina equisetifolia (Swamp Oak).—Found growing in great abundance near salt-water marshes and inlets. The wood is coarse-grained and beautifully marked. It is used for purposes where lightness and toughness are required. Casuarina torulosa (Forest Oak or Beefwood).—A small tree, occupying large tracts of land in the open forest. The timber is much used for fuel. It is close and prettily marked, and gives handsome veneers. Casuarina glauca (The River She-Oak).—A robust tree of general occurrence on the borders of rivers and creeks. The timber is strong and tough, used for staves and shingles. Casuarina Cunninghamiana (Scrub She-Oak).—A small but handsome tree; timber hard, close, and prettily marked."

— WE have received Part 24 of the work on "FAMILIAR GARDEN FLOWERS," now being issued by Messrs. Cassell, Petter, Galpin, & Co. It contains coloured plates of *Narcissus incomparabilis* and *Tropæolum peregrinum*, accompanied by interesting descriptive and historical notes.

#### THE COMPASS PLANT.

IN the "Botanical Magazine" for January Sir Joseph D. Hooker gives the following interesting particulars concerning the Compass Plant of America (*Silphium laciniatum*), of which many remarkable and even exaggerated accounts have been published lately.

This noble plant was introduced into Europe in 1781 by M. Thouin, and flowered for the first time in the Botanic Garden of Upsala in Sweden. It has been in cultivation in Europe ever since, though its name and fame as the Compass Plant of the prairies is of comparatively modern date, it having before that borne the popular names of Turpentine Plant and Rosin-weed, except amongst the hunters and settlers in the western States. With regard to the history of its reputed properties as an indicator of the meridian by the position of its leaves, I am fortunate in having recourse to my friend Professor Asa Gray, now in England, who has most kindly furnished me with the following very interesting account of this matter:—

"The first announcement of the tendency of the leaves of the Compass Plant to direct their edges to the north and south was made by General (then Lieutenant) Alvord, of the U.S. army, in the year 1842, and again in 1844, in communications to the American Association for the Advancement of Science. But the fact appears to have long been familiar to the hunters who traversed the prairies in which this plant abounds. The account was somewhat discredited at the time, by the observation that plants cultivated in the Botanic Garden at Cambridge, U.S., did not distinctly exhibit this tendency. But repeated observation upon the prairies, with measurements by the compass of the directions assumed by hundreds of leaves, especially of the radical

ones, have shown that, as to prevalent position, the popular belief has a certain foundation in fact. The lines in 'Evangeline' were inspired by a personal communication made by Gen. Alvord to the poet Longfellow.

"Look at this delicate plant that lifts its head from the meadow,  
See how its leaves are turned north, as true as the magnet;  
This is the Compass Flower, that the finger of God has planted  
Here in the houseless wild, to direct the traveller's journey  
Over the sea-like, pathless, limitless waste of the desert.  
Such in the soul of man is faith."

"I cannot congratulate the poet on the fidelity of the description of the plant as a 'delicate' one.

"Since the leaves tend to assume a position in which the two faces are about equally illuminated by the sun, it might be suspected that their anatomical structure was conformed to this position. This has been confirmed, first by Mr. Edward Burgess, who, when a pupil of mine, observed that stomata were about equally abundant on the two faces of the leaf; and next by Mr. Arthur of Iowa, who has recently published in Prof. Bersey's 'Introduction to Botany,' a figure of a section of a leaf, showing that the arrangement of the 'palisade cells' of the upper and lower strata is nearly the same. The leaves always maintain a vertical position, except when overborne by their weight. As to their orientation, not only is this rather vague in the cultivated plant, but subject to one singular anomaly which may be commended to Mr. Darwin's attention. I have several times met with a leaf abruptly and permanently twisted to a right angle in the middle; so that, while the lobes of the basal half pointed east and west, those of the apical half pointed north and south."

To the above I have little to add. I have not been able to detect any orientation of the leaves in the Kew cultivated specimens, but these, not being planted in a good exposure all round, are out of court as witnesses. On the other hand, when traversing the prairies with Dr. Gray in 1877 I watched the position of the leaves of many hundred plants from the window of the railway car, and, after some time, persuaded myself that the younger more erect leaves, especially, had their faces parallel approximately to the meridian line. I may mention that I, on the same occasion, convinced myself that the flower-heads of various of the great Helianthoid Compositæ, that grew in hosts on the prairie, did follow the sun's motion in the heavens to a very appreciable degree—their morning and evening positions being reversed. This observation did not, however, extend to the Compass Plant, the rigid stout peduncles of whose flower-heads would not be expected to favour such a motion.

Though never before figured in any English work, the Compass Plant has been for many years in cultivation in Kew, where it forms a very striking object, growing 8 feet high, and flowering profusely in August and September in the herbaceous ground. In the United States its range is from Michigan and Wisconsin westward to the Rocky Mountains, and south to Texas and Alabama.

## ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 8TH.

PRIMULAS, Orchids, and Grapes constituted the chief features at this meeting, the first-named occupying a large space, and forming an attractive group. There was a large attendance of the members of the Committees.

FRUIT COMMITTEE.—W. Paul, Esq., in the chair. Mr. J. Wallis, The Gardens, Keele Hall, sent a box of Grapes consisting of Gros Colman in fine condition, and Golden Queen, which was not so good. A cultural commendation was awarded. Mr. G. T. Miles, Wycombe Abbey Gardens, sent samples of new and old Grapes, the former being Black Hamburgh, and the latter Lady Downe's. The Black Hamburghs were very fine. A cultural commendation was awarded. Mr. Hudson, The Gardens, Gunnersbury House, Acton, sent twelve bunches of very handsome Lady Downe's Grape. They had been kept in bottles for five weeks. A cultural commendation was unanimously awarded. Mr. Miles also exhibited three very fine specimens of Lord Carington Pine Apple, for which a cultural commendation was awarded. Messrs. Saltmarsh & Son exhibited a seedling Apple of deep yellow colour with an orange cheek, marked with broken streaks of crimson. It had a tender flesh and an agreeable sub-acid flavour. It was not of sufficient merit to obtain a certificate. Mr. Miles, gardener to Lord Carington, exhibited eight handsome fruits of Petch's Favourite Cucumber, to which a letter of thanks was awarded. Mr. Gilbert, The Gardens, Burghley, sent a pair of Montrose Seedling Cucumber, a cross between Sion House and Kenyon's Freebearer. It is a pretty Cucumber, about a foot long and very symmetrical. Another seedling called Verdant Green was exhibited by Mr. J. McIndoe, The Gardens, Hutton Hall, Guisboro'. Messrs. Backhouse & Son of York again exhibited a seedling Onion which had been sent to a former meeting. The Committee were still of the same opinion as they expressed on a former occasion, that

there is no difference between it and the Red Spanish. Mr. John Clarke, Sycamore Gardens, Rowledge, sent a dish of Tomatoes. Mr. Lyon, gardener to Sir Edward Scott, Sundridge Park, Bromley, sent a very fine dish of Mushrooms, which were much admired, and to which a cultural commendation was awarded.

FLORAL COMMITTEE.—Dr. Denny in the chair. Messrs. James Veitch & Sons, Chelsea, exhibited a handsome group of Orchids in flower, among which *Odontoglossums* strongly predominated. Some examples of *O. Alexandræ*, *O. cirrhosum*, and *O. Pescatorei* were particularly noticeable. The charming little *O. blandum* was well represented. *O. Roezli* and the variety album, with *O. nevadense*, *O. Andersonianum*, and *O. triumphans*, were also well shown. A central plant of *Ada aurantiaca* had seven fine spikes, and a specimen of *Anthurium Andreanum* was staged with one of its peculiar brightly coloured spathes. A specimen of the *Chimonanthus*-like *Hamamelis virginica* var. *arborea* was shown in flower. A silver Flora medal was awarded for this collection. Mr. W. Bull, King's Road, Chelsea, sent several new plants, including two Palms, one named *Astrocaryum Malybo*, and the other *Kentia Lindenii*, the latter rather elegant. A variety of *Rhipidopteris peltata*, appropriately named *elegans*, was also staged, together with a plant of *Vriesia Falkenbergii* and *Maranta crocata*, described below, for which first-class certificates were awarded.

Mr. B. S. Williams contributed a grand collection of *Primulas*—dwarf, of good habit, and bearing fine trusses of bloom. *P. fimbriata coccinea* and *fimbriata alba* were especially noteworthy, the former for the size of the flowers and deep colour, and the latter for the purity of the white and the large trusses. *P. fimbriata alba* magnifica was in the size and form of the flowers remarkably fine, but the trusses were not sufficiently developed to show the variety to the best advantage. *P. fimbriata Chiswick Red* were very bright, *P. fimbriata rubra* and several others being particularly fine. A group of *Cyclamens* was also contributed, the plants well flowered and of good habit, *C. persicum Brilliant* being remarkable for their intense crimson of the blooms. A silver Banksian medal was awarded for these handsome groups.

Mr. W. Taylor, The Gardens, Longleat, Warminster, was accorded a vote of thanks for cut flowers of *Pelargonium Guillon Mangilli*, which has been referred to so many times in these pages recently. Mr. John Odell, florist, Hillingdon, Middlesex, sent specimens of a large-flowered variety of *Primula sinensis* named *Purity*; but it was not considered sufficiently distinct to merit a certificate. Mr. H. Boller, Kensal New Town, was accorded a vote of thanks for a group of miniature succulent plants. Mr. John Matthews, the Royal Potteries, Weston-super-Mare, sent some ornamental flower vases and small Orchid pans similar to those employed in Messrs. J. Veitch and Sons' nursery at Chelsea. From the Society's garden came attractive groups of double *Primulas*, *Cytisuses*, *Azaleas*, *Ferns*, and *Selaginellas*. Mr. J. Osborn, gardener to H. J. Buchan, Esq., Wilton House, Southampton, sent a plant of *Odontoglossum Wallisi* bearing a spike of yellowish flowers with a pink-tinted lip; and Mr. A. Wright, gardener to J. Brightwen, Esq., The Grove, Great Stanmore, exhibited a plant of *Aerides cylindrica*, closely resembling in stems and habit the peculiar *Vanda teres*, but differing in the flowers, which were of moderate size and white.

First-class certificates were awarded for the following plants:—

*Maranta crocata* (Bull).—A pretty species, with elliptical leaves 3 or 4 inches in length, shining green on the upper surface and purple beneath. It is dwarf and compact in habit, and produces scapes 5 to 6 inches in height, terminating in a small head of orange-coloured imbricated bracts, in the axils of which the flowers are borne; but the beauty of the plants rests in the bracts.

*Vriesia Falkenbergii* (Bull).—One of the plants which Mr. Bull staged in his collection of new plants at the last summer exhibition of the Royal Horticultural Society. It has dark green leaves 1½ inch in breadth, slightly recurving, and purplish beneath. The spike is about 8 inches high, with large closely imbricated crimson bracts, with white apices at the upper portion of the spike.

*Primula Dr. Denny* (Cannell).—A variety of *P. sinensis* with very large flowers 1½ inch in diameter, very rich crimson colour, good form, and distinct yellow eye.

*Lachenalia Nelsoni*.—This was stated to be a seedling cross between *L. luteola* and *L. aurea*, and was exhibited by the Rev. J. G. Nelson, Aldborough Rectory, Norwich. The scape was 8 or 9 inches in height, with pendulous tubular yellow flowers, with a tint of orange in the buds and at the upper portion of the spike. It combined in a marked manner the characters of the two parents, but was superior to both in vigour of habit and size of the flowers.

*Cineraria William Jennings*.—This and the following were exhibited by Mr. James, gardener to Mrs. Watson, Redles, Isleworth, and occasioned some discussion as to the advisability of certifying varieties of *Cineraria*, but the majority were in favour of doing so. The variety named above had handsome symmetrical flowerheads about 1½ inch in diameter, and in colour a remarkably rich purplish crimson self.

*Cineraria Master Colvin* (James).—Also of excellent form and substance; the colour being a warm shade of purple with a narrow clearly defined ring of white near the centre.

*Hamamelis virginica* var. *arborea* (Veitch).—A peculiar *Chimonanthus*-like plant, with dense clusters of small flowers clothing the leafless branches. The flowers are small individually, but collectively

they produced a rather pretty effect owing to each having four long narrow yellow petals, and the same number of short reddish sepals.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair. Dr. Masters read a letter containing resolutions of the Imperial Horticultural Society of Russia on the introduction of the phylloxera into the Crimea—*e.g.*, that the Vine only shall be excluded either as "plants" or "eyes," and without a ball of earth; and if plants be sent from countries where the Vine is cultivated they shall only be admitted with a certificate to prove that the Vine had not been grown

at the same place. Fruits of all kinds (Grapes and raisins excepted) shall be freely admitted. The importation of all kinds of plants from the Crimea shall be provisionally forbidden.

*American Blight.*—In view of the extensive diffusion of this insect the Committee demand the disinfection of the invaded districts, and the prohibition of all importation of Apples. Specimens of Wheat haulm affected with grubs were given to Mr. McLachlan to report upon.

*Cordyceps sp. Attacking Larvæ.*—Mr. McLachlan exhibited the larvæ

Fig. 25.—URCEOLINA PENDULA. (See next page).

of some wood-boring beetle attacked by a Cordyceps, growing, as is the case with other species of Cordyceps, from the neck of the caterpillar. A question arose as to whether the spores were taken in with the food or by the larva burrowing and so getting them inserted into the folds of the neck, as the President suggested.

*Moth Attacked by an Isaria (?)*.—He also exhibited a small white moth with a branching fungus proceeding from the thorax, apparently an Isaria. It was referred to Dr. M. C. Cooke to report upon.

*Hybrids Between Frogs and Toads.*—Mr. Boulger asked if the account in the "Rev. Belg. Hort." on the existence of the above was a fact. The President believed that it had not been confirmed. Rev. H. Crewe said from his observations such an occurrence might possibly be true.

*Camellia Leaves Attacked by a Fungus.*—Some leaves were forwarded by Mr. Duffield of Winchmore Hill, and were referred to Mr. W. G. Smith to report upon.

The Rev. G. Henslow (Secretary) exhibited some Bamboos, showing in one case horizontal nodes, in another oblique, the popular idea being that the latter were grown on hillsides, and such growth strengthened the stem. The President negatived this view, and said it was a specific characteristic only.

*Wood Attacked by a Fungus.*—He also exhibited a piece of wood, which appeared to have been partially sawed through and the surface rendered irregular by the attack of some fungus.

*Parmelia parietaria.*—He also showed a specimen on a rock from Cheddar, exhibiting curious zones of lichen.

*Pottery Stained by Tobacco Juice.*—He also exhibited pieces of chinaware, ornamented by placing a drop of tobacco juice on the unbaked clay. This penetrates by capillary attraction, and forms a dendritic arrangement, which is fixed by sizing and baking.

### URCEOLINA PENDULA.

THIS beautiful Amaryllidaceous plant was discovered by Mr. Pearce in Peru, and sent out in 1866 by Messrs. Veitch, Chelsea. It was figured in the "Botanical Magazine" for September, 1864, and received a first-class certificate from the Royal Horticultural Society.

The leaves are broadly ovate, not unlike *Eucharis amazonica*, but considerably modified in size and texture, and are deciduous, though in young non-flowering plants the foliage is frequently retained over the resting period. The flowers are produced in an umbel of gracefully drooping bell-shaped flowers, bright yellow tipped with green, and supported by a scape 9 to 15 inches in height according to the vigour of the bulbs. It is a singularly graceful and peculiarly pleasing and showy plant, and of a colour uncommon in stove bulbs. It flowers freely, usually in autumn. I have had plants flower in September and as late as January.

It is of easy culture and does not require much room. The majority of our plants are in 5-inch pots, and 6 and 7-inch pots are quite large enough for the largest bulbs, or three to five may be grown in the latter size of pot; but there is no advantage in this, for it is seldom that all the bulbs flower simultaneously. Potting is best done in February or early March, taking care not to injure the roots. Turfy loam with a little leaf soil and a dash of sand grows it perfectly. Water is required freely when in growth, yet it must be applied judiciously, as an excess will cause the roots to perish. It requires to be grown near to the glass, and succeeds admirably in a cool stove temperature. The bulbs in potting should be covered level with the neck. When the leaves show indications of maturing lessen the supply of water, and after going to rest keep the soil moist. It is increased by offsets.—G. ABBEY.

### HARDY FRUIT GARDEN.

COMPLETE the pruning of Apricots, cutting back any attenuated spurs, and thinning out those that are crowded, and also cut out some of the long growths. Lay in young wood where space permits, but avoid overcrowding; if you desire to obtain fine fruit it is essential that the wood be freely exposed to light and air. If the trees are not unnailed or untied the ligatures should be carefully examined, and if any growths are too tightly secured the ties must be loosened, as inattention to this matter induces the production of gum and causes other injuries.

The pruning of Peaches and Nectarines should be proceeded with, thinning out crowded long bare branches, and so disposing those retained as to equalise the growth as far as practicable. Trees that are loosened from the walls should be dressed with some approved insecticide, whilst those not loosened should be well syringed with the same, also attending to previous remarks concerning the ligature. The branches of a Peach or Nectarine should be 12 to 15 inches distance apart, and the bearing wood a similar distance asunder along them, and starting from the upper side. The bearing wood—i.e., shoots of last year, if not more than a foot in length need not be shortened, especially if, as often occurs at the lower part of the tree,

the buds are mostly bloom buds, and at the upper part wood buds only; but stronger and more elongated growths may be cut back to about 10 inches from the base or to a well-situated wood bud. Extensions need only be shortened as necessary to originate growths where required for covering the space regularly, this applying more especially to the centre or upright part of the trees; the side extensions need only be cut back so as to remove immature wood.

### FLOWER GARDEN.

Borders containing herbaceous plants, bulbs, &c., should be neatly forked over, taking advantage whilst working among them to reduce plants that have become too large, or to divide and increase the choice or desirable. Lilliums may now be planted, being very effective in borders backed by evergreens, or among Rhododendrons in the peat and open spaces of which they revel. The bulbs should be planted about 6 inches deep, and be covered and surrounded with sand. Gladioli for early flowering should now be planted, especially of the ramosus section, treating similarly to the Lilliums. Plant Anemones and Ranunculuses in deep rich soil with a pinch of sand around them, sowing seed of Anemone for autumn flowering. Make a sowing of Sweet Peas and Mignonette in a warm situation for early flowering. Roses and other climbers on walls and trellises should now be pruned, regulated, and tied in. Any standard or dwarf Hybrid Perpetual Roses required to bloom early should be pruned at once, deferring the main pruning until later.

Forward the propagation of all bedding plants from stock plants as cuttings are available. Tricolor and other choice Pelargoniums should have a little heat, so that cuttings may be obtained, which may be partly severed and left on the plants a week or ten days to callus, afterwards detaching and potting them in small pots placed on shelves near the glass. Roots of any choice Dahlias may be plunged in a bed of cocoa-nut fibre refuse, in which the young shoots root freely, they can then be taken off and potted. No time should be lost in sowing seed of subtropical and other bedding plants, such as *Acacia lophantha*, *Centaurea*, *Cineraria*, *Ferdinandias*, *Melanthus*, *Solanums*, *Wigandias*, &c.; but those of quick growth, such as *Amaranthuses*, *Ricinus*, *Zeas*, &c., should not be sown until early April. Divide and place in heat Cannas and similar plants, starting all stock plants required for propagating. Herbaceous Lobelias may now be divided and started in gentle heat. Calceolarias wintered in store pots or boxes should now be planted out in cold pits or frames. Pansies and Violas struck in autumn may now be planted out permanently: they like rich moderately stiff loam, or, failing this, dress the beds with decayed manure. Pot off autumn-struck cuttings of *Ageratums*, *Abutilons*, *Heliotropes*, *Pelargoniums*—indeed all plants likely to suffer by remaining in store pots. Whenever cuttings are to be had of *Alternantheras*, *Coleuses*, *Iresines*, &c., insert them without delay.

### PLANT HOUSES.

*Greenhouse.*—Pelargoniums as they fill their pots with roots will require more water or the leaves will suffer. Treat the Fancy varieties with care in this respect, as they cannot bear so much moisture at the roots as the large varieties. Keep the plants near the glass, and well tied out. Promptly fumigate upon the appearance of aphides. Calceolarias should be potted as they require it; small-sized plants in 6 or 7-inch pots are most suitable for general decoration, but where desired they may be grown larger by shifting them into 8 or 10-inch pots. Assist growing plants with liquid manure. Lilliums will be pushing, and should be placed in a good light position so as to induce a sturdy growth. A pinch of *Cineraria* seed sown now will produce plants that will flower early next winter, and be useful, especially the self-coloured blue and shades of crimson and purple.

*Daphne indica* is much appreciated for its fragrance, but is seldom seen in good condition, chiefly because it is frequently overpotted and overwatered. Plants that were brought early into flower should be encouraged to grow by placing them in a night temperature of 50°, with a rise of 5° to 10° by day, syringing lightly overhead. Examine the roots, and if they fill the pots transfer to others a couple of inches larger, employing either turfy loam or fibrous peat, with a free admixture of sand.

## THE BEE-KEEPER.

### CONGRESS OF GERMAN AND AUSTRIAN BEE-KEEPERS.

(Continued from page 34.)

DR. POLLMAN read a paper on "The Way to Cure a Colony which Breeds Drones Only." The statements of this highly educated bee-master gave rise to a rather excited discussion. Clausmeyer proposed to remove the entire colony, and to put another queen with a few brood combs into the hive, allowing the drone-breeding colony to enter that part of the hive intended for the storage of honey. The honey-gathering bees of the latter colony in that case would join the new queen, while the drone-breeding queen would be stung to death. But Mr. Clausmeyer would very rarely attempt to cure a drone-breeding colony except in spring. In the autumn he would destroy such a stock without the least hesitation.

Count Pfeil introduced the question, "How may the queen be prevented in the most simple and inexpensive manner from having access to that division in 'Stander' and 'Lager' hives intended for the storage of honey." The speaker objected to the queen-excluder, and recommended Vogel's canal, which, by-the-by, Mr. Vogel, the distinguished author, is too modest to call his own invention. Mr. Gübler replied that he was in favour of the use of perforated zinc, the introduction of which would change the entire system of bee-keeping on scientific principles. Breeding would in future take place in the division for the honey, and honey would be stored in the division for the brood. Colonies of bees need no longer be separated, only the queens must be excluded at the proper time. Knobel of New-wied mentioned some of the drawbacks of Vogel's canal, his principal objection to it being that it is an obstacle in cases when hives are to be removed to another place.

#### FOUL BROOD.

Mr. Frey of Nuremberg favoured the meeting with a most instructive speech on foul brood, the most dreaded of all diseases of bees. Starting with a few general remarks as to the origin of low organisms the speaker proceeded as follows:—The fungus of putrefying matter consists of exceedingly small thread-like or oval cells, which increase very rapidly by continuous division. Bacteria, which are the cause of foul brood in bees, belong to the same class of fungi. Time will not allow me to enter fully into a description of the putrefaction of the brood. I can merely state in a few words the conditions which favour the spread of this destructive disease, and the means the bee-keeper should adopt to combat it successfully. Foul brood is of two kinds—1st, Non-contagious; 2nd, Contagious. The former may be caused by rainy or cold weather chilling of the bees, and especially the brood; uncleanliness while stimulative food is administered; feeding with honey or pollen in a state of fermentation; too high a temperature in the hive, and in consequence copious condensation of aqueous vapour. The latter may be caused through healthy bees robbing colonies infected with foul brood, uniting healthy and diseased colonies while they are breeding, and through placing a colony into a hive which has been inhabited by bees suffering from foul brood. In an apiary where bees infected with foul brood have stood there is always danger of the disease breaking out again, even after the lapse of several years. Infection is also possible through aphides, honey which contains an enormous number of fungus spores, flowers on which diseased bees have been may become the vehicle of foul brood; and lastly may be mentioned feeding with honey taken from stocks actually infected with foul brood, and want of caution on the part of the bee-keeper. And what can the bee-keeper do to combat this dreadful disease? 1st, He should take the proper means to prevent its appearance by arresting the conditions favourable to the development of the disease, or should try to lessen their injurious effect. 2nd, The bee-keeper should employ the proper means to stifle the disease should it have made its appearance. Upon the destruction of the vitality of the fungus which causes the disease depends the cure of the colony. The various substances which will destroy the fungi of fermentation are called antiseptics, and a great many of them are known in chemistry, such as sulphur, chloroform, salicylic acid, spirits of wine, &c.; but only a few of these can be employed for our purpose. Carbolic acid has been used to cure foul brood, and is recommended. I need not therefore refer to it, but I may mention salicylic acid, a substance closely related to carbolic acid, and composed of exactly the same elements. Its effect is about one-third of that of carbolic acid, and Nature herself offers it to our bees in the flowers of the Meadow Sweet (*Spiraea Ulmaria*). This plant grows in Germany and England in damp meadows, &c. By encouraging the cultivation of this plant bee-keepers would provide a natural preventive against foul brood. Bees are fond of visiting the flowers of this plant, but if the plant were dried and then rubbed to powder and mixed with the food in spring it would probably also be of considerable benefit to bees. The speaker further mentioned boracic acid and a few other chemicals which have antiseptic properties.

Pastor Rabbow stated that there had been cases of foul brood in his district which, however, had disappeared without any measures

having been taken to cure it. He was inclined to think that the bees themselves had effected the cure through visiting the *Spiraea Ulmaria*, which plant is frequently met with in that part of the country.

After the close of the discussion it was decided unanimously that the next meeting should be held at Erfurt in 1881; Mr. Breslau, the Burgomaster of Erfurt, and Mr. Frankenhäuser of Gispersleben being elected President and Vice-President respectively by a large majority. The cities of Buda Pesth and Frankfort-on-the-Maine were proposed for 1882. A banquet was then held, and the next day the prizes were distributed by the Burgomaster, when I had the pleasure of receiving at his hands a silver medal for a collection of articles used in bee-keeping. As the publication of the awards made to our accomplished foreign friends would not be of general interest to British readers I will next describe a visit to a German apiary.—ALFRED NEIGHBOUR.

#### REVIEW.

*Handy Book of Bees.* By A. PETTIGREW. Fourth Edition, Revised and Enlarged, 1881. W. Blackwood & Sons.

WE congratulate Mr. Pettigrew on the well-merited success of his "Handy Book of Bees." It may well be called the *vade mecum* of profitable bee-keeping for all who look for large honey harvests, while managing their bees as little divergently as possible from the old-fashioned straw skep principle. Honest common sense and a thoroughly practical acquaintance with his subject is manifest in all he says of matters within the range of his experience. He can be thoroughly trusted here, and no one who follows his guidance can go wrong. As he says himself, "the most important chapter in the book" is that wherein he treats of "hives." Everybody knows that he has for several decades been waging war against the ridiculously small hives still too commonly in use throughout England and Wales. Very gradually he has won for himself a hearing, and we believe that no one has been disappointed who has fairly tried his large straw hives in anything like a fairly good country for honey. "The proof of the pudding is in the eating," and where tens of pounds used to be harvested, and that only in exceptionally good seasons, it is not uncommon to find hundredweights of delicious honey garnered in the autumn time—thanks to Mr. Pettigrew's improved hives. Therefore, all bee-keepers whose one object is profit at the least possible cost owe him a large debt of gratitude.

We should like to content ourselves with this favourable notice of the book, which we honestly think one of the best bee books that was ever written; but we should not be impartial in our criticism if we did not express our regret that Mr. Pettigrew does not confine himself to pressing upon public notice the manifest advantages of things within his own experience, but that he allows himself to run tilt in no measured language against the proved successful experiences of others. Hives of wood of every kind, whether bar-framed or otherwise, are unsparingly condemned, and their inventors and manufacturers, as well as those who use them, appear in his eyes to be wanting in sound judgment. "Prejudice," "selfishness," not to say "successful humbuggery"—the latter term borrowed from an American author—is rather strong language to be applied indiscriminately to his brother apiarists who do not exactly see through his glasses. If, therefore, Mr. Pettigrew's book sees a fifth edition, which its intrinsic merits well deserve, we would suggest to him the advisability of rewriting the pages in which he thus vilifies as honest men as himself. The book will then be almost faultless so far as it goes, and will only minister to the profit and pleasure of those who read it.

On one more point, however, we must still question (and it has often herein been questioned), the soundness of Mr. Pettigrew's judgment. We refer to his opinion respecting honey. He tells us that what bees collect in the nectaries of flowers is "not honey proper;" that the "sweet juice" which they bring in from the fields is by them "converted" into honey. "They reswallow it at night, thus making it into real honey." Now, shall we venture to say that this is a "prejudice" in the proper sense of the term? Certainly it is "not proven." This fact might also well be omitted in a future edition; for, to paraphrase Mr. Pettigrew's own words, "the stating of certain opinions will not satisfy an intelligent person unless his mind be fully convinced by the reasonableness of such statements," (p. 35). Such "opinions" will never be admitted as facts till they have been demonstrated to be so by irrefragable evidence.

#### TRADE CATALOGUES RECEIVED.

Henry Hope, 55, Lionel Street, Birmingham.—*Illustrated List of Horticultural Buildings.*  
J. Carter & Co., 237 and 238, High Holborn, London.—*Catalogue of Popular Collections of Vegetable and Flower Seeds.*

Sutton & Sons, Reading.—*List of Disease-resisting Potatoes.*  
Orniston & Renwick, Melrose.—*Catalogue of Flower and Vegetable Seeds.*

Strike and Hawkins, 62, High Street, Stockton-on-Tees.—*Catalogue of Vegetable and Flower Seeds.*

Harrison & Sons, Leicester.—*Price List of Seeds for the Garden and Farm.*

E. G. Henderson & Son, Pine Apple Nursery, Edgware Road.—*Catalogue of Flower and Vegetable Seeds (Illustrated).*

Richard Dean, Ranelagh Road, Ealing, London.—*Catalogues of Seeds, Plants, and Potatoes.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (J. M., Ireland).—If you write to Messrs. George Neighbour and Son, 127, High Holborn, London, you will obtain the information you require.

Tinnea æthiopica (F. S.).—We do not know where you could purchase seed of this plant, but we believe small plants are obtainable from some of the chief metropolitan nurserymen.

Insect on Vinc (W. Martin).—Thanks for information sent. We should be glad to see further specimens, if any should occur in the spring, since it is doubtful whether flies can be reared from those already received. Your precautions were wisely taken; at the same time we rather incline to the opinion that the larvæ which had developed in the pupæ sent had not fed upon the Vine, but that their appearance might be otherwise explained.

The Pine Apple Nursery (Curiosity).—This nursery was established by Mr. Andrew Henderson, who was succeeded by his son of the same name; from him it passed to Mr. John and Mr. Arthur Henderson. In 1871 Mr. John Weeks purchased the business, and sold it in 1876 to the firm of Messrs. E. G. Henderson, of the Wellington Road Nursery; and the present proprietor of the Pine Apple Nursery is Mr. Andrew Henderson.

Magnum Bonum Potatoes (W. G., Elmdale).—The Potatoes you sent confirm what you have said respecting their quality. They were very good. Their cropping and disease-resisting properties are generally admitted, and the variety has given satisfaction to nearly all cultivators who have grown it under favourable conditions. We have tasted several samples, and those grown on moderately fertile land in open fields have usually been of better quality than larger tubers grown in the richer soil of gardens.

Primulas and Cinerarias (Devon).—You appear to have a good strain of Primulas, the colours being varied and some very rich; the flowers are also of good form, but there are better strains in cultivation; for instance, some flowers we recently received from Mr. H. Cannell of Swauley were considerably finer in all respects. The colours of the Cinerarias are good, but the majority of the flowers are very small.

Planting a Ribbon Border (H. Dod).—Four rows will be sufficient, as overcrowding mars the effect of such borders. The mode of arrangement is usually determined by the plants at disposal. We submit three modes of planting, any of which would look well, good plants being employed and the border kept in good condition. The names must be read from the front to the back of the border: 1, Dwarf blue Lobelia, Golden Feather, dwarf Ageratum, and scarlet Pelargonium. 2, Cerastium, Lobelia, silver-variegated Pelargonium, and Perilla, Beet, or some other dark-foliaged plant. 3, Dactylis glomerata, Viola Blue Bell, dwarf scarlet Pelargonium, and tall yellow Calceolaria. The address you require is Messrs. Arnold & Sons, 35 and 36, West Smithfield, London, who will give you the information that we are unable to supply.

Bedding Pelargoniums in Hyde Park (Old Subscriber).—If you refer to page 424, in the issue of November 4th, 1880, you will find a list of the principal varieties that were grown in the above Park and at the Crystal Palace during the past two seasons. If you do not possess this number, it can be had from the publisher in return for 3½d. in postage stamps. We do not know the varieties "Paul Labby" and "Nealey," nor where they can be obtained; perhaps some of our readers can supply the information.

Early Potatoes (J. Cheam).—Myatt's Prolific is one of the most serviceable early varieties in cultivation, being an excellent cropper and the produce of good quality. We have not tested the new Wiltshire Snowflake with it, which is nearly twice the price of Myatt's. You had better try a small quantity of the new variety and ascertain whether it is well adapted for your soil. The address you require is Mr. R. Dean, Ranelagh Road, Ealing, London, W.

Glazing without Putty (J. T. Sinclair).—Copper tacks about an inch long are suitable for squares not exceeding a foot in width. They should taper to the points, and have their heads similar to ordinary "clip" nails, so that the whole length of the nail rests on the glass when driven into the sash above it; if driven in about half an inch or a little more the glass will be perfectly safe. It is important that it be well and carefully embedded in the putty, and a roof is then perfectly watertight. The putty which rises upwards when the glass is pressed firmly down on it must be neatly removed before the sash-

bars (outside) are painted, and a strip of paint should cover the glass as wide as the rebate in which it rests.

Sowing Choice Peas (T. Westlake).—You probably cannot do better in "making the most of" your few choice Peas than to follow the advice of "A KITCHEN GARDENER" on page 29 of the present volume; but instead of sowing the seeds in 3-inch pots, we should prefer sowing half a dozen peas in 4-inch pots, which must be washed clean and be quite dry before the soil is placed in them, otherwise the roots may be injured when turning them out of the pots. Two things are important in this matter—the Peas must not be drawn by remaining too long under glass, nor the pots must not be firmly matted with roots when the plants are transferred to the open ground. As soon as there are sufficient roots to hold the soil together is the time for planting, and the seed should germinate in a cool frame. With good ground and a little fresh light soil placed round the roots at planting you will produce a good if a short row of Peas from the seeds at your disposal. We do not know that the "Earliest of All" Pea is in commerce; if it is Mr. Laxton will probably give information on the subject.

Vines Unsatisfactory (G. F., Devon).—You have not given us sufficient information to enable us to comprehend the condition of your Vines. You do not even state their age nor the character of the wood and foliage that they produce. They may be worn out entirely, or need their roots lifting, but at any rate you cannot err by removing the soil down to the roots, just baring without injuring them, and adding fresh soil. This should consist of fresh turfy loam mixed with a fourth of manure (if the loam is not rich), a bushel of bones to each cartload of soil, and as much burnt refuse and wood ashes as you like. This may be placed on the roots to a depth of 6 inches, and be covered with a layer of rich manure. Copious supplies of liquid manure during the summer would doubtless be very beneficial, and in all probability it would be desirable to train a young cane from each Vine preparatory to removing the old rods. We have seen the finest of Grapes produced by Vines trained as yours are. If you can produce strong growths and good foliage kept clean and not crowded good Grapes will follow.

Early Potatoes (John Elliott).—There are a number of good short-topped early kidney Potatoes such as you require, but the list of early round varieties with short tops is somewhat limited. Several firms catalogue improved forms of Early Ashleaf; and though they may be as good as, it is doubtful if they are superior to Veitch's. This with Mona's Pride, the Early Hammersmith, and Early Bird are all good. To either of the foregoing may be added Rivers' Royal Ashleaf, which is a heavily cropping profitable variety. The haulm of Extra Early Vermont (the best of the Early Rose section) is not so short as the old Ashleaf, but in other respects you would find it excellent. Of round varieties we give the preference to Fox's Seedling and the American variety Alpha. Early Oxford produces less haulm than the latter, and the quality of tubers is good, but it does not crop so heavily. Early Coldstream is worthy of trial. Triumph (American), a red variety, is heavy-cropping and short-topped, and worth a trial to succeed Fox's Seedling. You did not stipulate for exhibition varieties, and the foregoing are recommended for their table qualities; and more than the required number (four) are mentioned simply because all are not advertised, we believe, by any one firm.

Walcheren Cauliflower for Succession (Idem).—It is not generally considered good policy to rely exclusively on one variety for maintaining an unbroken supply of Cauliflowers through the season, but by repeated sowings it is possible to accomplish the feat with the Walcheren. This variety does not succeed satisfactorily on all soils, and the stock cannot always be relied upon. A deep, newly enriched, loamy soil appears to suit it, and indeed Cauliflowers generally. A pinch of seed should have been sown at the end of last August, the plants obtained being pricked out in cold frames and given all the light and air possible during the winter. Towards the end of March or early in April, according to the weather experienced, part of the batch (the strongest plants) to be planted out in a warm sheltered position, and lightly protected from frosts with branches of evergreens or inverted pots. To succeed these the remainder of the autumn-sown plants may, a few days later, be planted in a cooler open spot. A small sowing to be made in gentle heat during February, the plants pricked out in boxes or in a frame, hardened off before becoming drawn, and towards the end of March finally planted out in an open spot. If you have no autumn-sown plants give this batch a warm position. Early in March, April, May, and June small sowings may be made in the open, and if the after treatment be liberal a good supply may be obtained till frost intervenes. During the prevalence of hot dry weather the plants will be much benefited by copious waterings and a mulching of short manure or litter of any kind.

Cucumbers and Melons (Melon).—You may sow the seeds now provided you have no difficulty in maintaining the temperature we advised last week, but if your house is lofty we doubt if you will be able to do that with only "one pipe running the length of the house" for top heat; this, however, you can easily ascertain. We doubt if you can grow a more suitable Cucumber than Telegraph; and good free-growing Melons that usually set their fruit freely are Victory of Bath and Eastnor Castle Green-flesh. As scarlet-fleshed varieties the Blenheim Orange (new) and Reid's Scarlet are good. To make the most of the seed we should place one seed in the centre of a 3-inch pot. The soil should consist of turfy loam and leaf soil, the pots being filled about three parts full, and not pressing the soil firmly. The seeds should not be placed flat in the soil but on their edges, and be just covered. If the soil is in a proper state as to moisture, that is, neither too wet nor too dry, and the pots plunged in the hotbed, no water will probably be required until the seedlings appear. When water is needed it must always be given in a tepid state, or a few degrees warmer than the house. When the roots of the plants appear on the surface of the soil add fresh warmed compost. When the plants are an inch or two high withdraw the pots from the hotbed and place them on it for a few days preparatory to removing them to a shelf near the glass, so that they may grow as sturdy as possible. The temperature of the house should then be 65° at night, 70° by day with fire heat alone, increasing to 85° with sun. Ventilate slightly by the top ventilators when the heat rises above 70°, and close in the afternoon as early as possible, so that the temperature afterwards does not rise above 85°. The greater the heat in the house the greater must be the amount of moisture by damping the paths, wall, &c. If you can raise strong healthy plants you will have surmounted the greatest difficulty, and you may then hope for a "measure of success." Liquid manure will not be required until the plants are bearing heavy crops, and a peck of fowl's dung will make you fifty gallons suitable for the purpose.

Worms in Flower Pots (Col. Simpson).—We know of no plan so safe for getting rid of worms as watering the soil thoroughly with lime water. If you place a lump of fresh lime, say about 2 lbs., in a pail of water and stir well, then let it settle for two or three days, skimming the film off the surface, you will have clear lime water, which, if applied to the soil, will cause the worms to rise to the surface of the pots, when they can be easily picked up and removed from the house. Others, however, will enter the pots from the

leaves in which they are plunged unless means are taken to prevent them doing so. The remedy you propose would not be a safe one. It would be better to mix lime and soot with the leaves, and in addition we should spread a thick layer of it just below where the base of the pots would rest when plunged. When the plants are potted, too, it is a good plan to first cover the drainage with fibry turf from which the soil has been shaken, or tree leaves, and on this drainage-protecting medium spread a thin layer of soot; this will in a great measure prevent the ingress of worms, and will be a suitable fertiliser for nearly all plants.

**Plants for Back Wall of Vinery** (*Idem*).—As you say the house is hip-roofed we presume the plants will receive light from the "hip." In this case, as you require fragrant flowers, we think few will be so satisfactory as such Roses as *Maréchal Niel*, *Belle Lyonnaise*, *Gloire de Dijon*, and *Cheshunt Hybrid*. *Heliotropes* will also be suitable, the old species being as good as any for this purpose. *Rhynchospermum jasmynoides* would succeed in such a position, and afford abundance of its pure white and sweet flowers. We have seen *Cytisus racemosus* cover a wall attractively, and produce its bright yellow honey-scented flowers freely in spring. A plant of the Lemon-scented *Verbeena* (*Aloysia citriodora*) would afford a large supply of highly perfumed sprays for cutting.

**Table Plants** (*J. P., Dublin*).—Suitable plants for growing in your stove for the above purpose are *Dracæna terminalis*, *terminalis alba*, *Cooperi*, *Ernesti*, *Sydneyi*, *jucunda*, and *gracilis*; *Crotons angustifolius*, *Johannis majesticus*, and *Weismanni*; *Aralias elegantissima*, *leptophylla*, and *Veitchii*; *Pandanus Veitchii*, *Cocos Weddelliana*, *Geonoma gracilis*, *Dæmonorops plumosa*, *Ananassa sativa variegata*, and *Reidia glaucescens*. *Adiantum cuneatum*, *scutum*, *assimile*, *gracillimum*, and the new variety *Bausei*, with *Pteris tremula* and *serrulata*, are useful among Ferns, and may be grown in the Cucumber house, as shade is beneficial rather than injurious to them during the summer. *Cyperus alternifolius* and *C. laxus* may be grown in a similar position if needed, and the variegated form is also attractive. The lovely *Caladium argyrites* does not object to shade while it enjoys heat and moisture. *Gloxinias* may be started on the bed in the Cucumber house, and be afterwards grown on shelves in the same structure, one of which can usually be suspended on each side of the path, and level with or above the trellis; such shelves would be of great value for all kinds of stove plants in a small state. Amongst flowering plants suitable for your purpose are *Gloxinias* in variety. *Tydasæ* (for culture and varieties see page 573 of last volume), *Gesneras cinnabarina*, *refulgens*, *zebrina*, and *exoniensis*, small plants of such *Begonias* as *insignis*, *fuchsioides*, and *metallica*, besides some of the tuberous forms, *Ixoras*, *Poinsettias*, *Euphorbia jacquiniæflora*, *Aphelandra aurantiaca* *Roezlii*, *Scutellaria Mocciniana*, *Epiphyllum truncatum*, with *Eucharises*, *Stephanotis*, *Gardenias*, and *Tuberoses* for cutting. The *Begonias* will require the coolest position.

**Spotted Lettuces** (*J. P.*).—The spotted Lettuces are rarely grown in England, and hence seed is not offered by seedsmen in this country. Amongst the varieties mottled with reddish brown that are grown on the continent are the *Spotted Tiger*, *Spotted Trout*, *Coblentz*, *Emperor's Head*, *Perpignan*, and *Sanguinea Panachée*, all of which are sold by E. Benary, Erfurt, Prussia. If you are ordering seeds from an English seedsman he would no doubt obtain you a packet of any one of these varieties; or you might send 1s. 6d. or 2s. to the address given, and ask for a packet of the best variety of the kind you would describe in your letter. The *Stanstead Park*, to be obtained of any seedsman, is usually a little spotted when young, but is not nearly so marked in that respect as the varieties above named. In respect to Lettuces not running to seed quickly, all does not depend upon the variety, as if required to "stand" well they must be well grown. The owners of many small gardens are apt to sow the seed very thickly, neglecting to either thin-out the plants or transplant till they are much drawn, and then perhaps in a position partially shaded by fruit trees, where oftentimes manure and moisture are insufficient. Sow often and thinly, either in rows, where the plants are to remain, thinning out early and freely; or in a bed, and transplant before the seedlings are crowded, selecting good open ground in both instances. Lettuce well repay good culture, and by following the above simple practice a supply may be maintained with either Cabbage or Cos varieties.

**Dressing Seeds with Paraffin** (*H.*).—It does not injure the seeds if they are merely damped with it. We have no doubt it would ward off attacks of mice, but doubt its effect upon birds. Nothing applied to the seed peas will prevent the young growth being eaten by birds, and we should rather syringe them with paraffin, using it at the rate of one wineglass to three gallons of water, keeping it stirred in the watering pot by discharging back each alternate syringe. If this fails wood ashes or soot and lime may be dusted over frequently when the growth is dewy, which may probably have the desired effect. With small seeds again the husks are not generally eaten, the embryo growth being the delicate morsel aimed at, and which is picked out when germination has commenced. A few yards of fish netting properly stretched over the seed beds is after all the most effective, especially in districts where chaffinches and sparrows are very voracious. The latter eat the seed leaves principally, and which are unaffected by any application to the seed, hence the advisability of using netting. If this is unobtainable Pea stakes may be substituted, carefully disposing them over the beds, birds not liking to venture among these.

**Relative Fall of Temperatures In and Outdoors** (*H. Yates*).—The temperature of a vinery being 65° when the thermometer outside was 32°, the temperature of the vinery would fall correspondingly, but not in the same ratio with the outside temperature. The outside temperature, for instance, shall be 32° at dusk; by 9 p.m. it has fallen to 12°, or 20° below freezing; the temperature in the vinery will have fallen about 4° or 5°, and if the external temperature continue at 12° through the night, the temperature of the vinery in the morning will be found between 50° and 55°. For the size of the house, the thickness of the glass, the openness or closeness of the laps, and the wind both in force and direction, will make a difference of about 5°. The reduction in temperature of an artificially heated structure is about half that of the decrease of the external temperature, or with a vinery at 65° with the outdoor 32° it would fall about half of the decrease of the outside temperature of 12° as your minimum, or to 55° in the course of six or nine hours, and remain stationary (presuming the frost to continue at 12°) at 50°. The higher the difference between the internal and external temperature the greater will be the divergence. There is a difference of 33° between 65° and 32°, and the loss will be about half, but with the internal temperature at 50° and outside 32° there is only a difference of 18°; and presuming the temperature outside to fall to 22°, the loss would not be so great, being about 10°. A great deal depends on the wind, the extent of the glass surface, and the continuance of the cold.

**Names of Plants** (*C. F.*).—The spray arrived much crushed and withered; it appears to be *Spiræa Thunbergii*, which you will find illustrated and described on page 131 of our issue of February 14th, 1878. If you have not preserved this

number it can be had from the publisher, price 3½d. This *Spiræa* is very useful for early forcing, and may be easily had in flower in January.

#### COVENT GARDEN MARKET.—FEBRUARY 9.

GOOD well-kept Grapes are now in demand and fetching good prices, otherwise our market remains the same; American Apples arriving in bad condition, sound samples realising better prices.

#### POULTRY AND PIGEON CHRONICLE.

#### WEEDS OF THE FARM, AND HOW TO DESTROY THEM.

(Continued from page 100.)

IN continuation of this subject we will briefly refer to the mode of destroying Docks, this being the last weed spoken of on page 100. We have always employed for the purpose a small pickaxe firmly fixed in a light but strong handle, which has a point at one end and a narrow cutting edge at the other, the former being used instead of the spud, and the latter for loosening the earth round the roots.

The field *Convolvulus*, with a pretty pink flower, is, of all our twining weeds, the most troublesome upon the best Turnip soils; and as these plants are perennial, with roots striking deep into the subsoil, they flourish in extremely dry seasons when the root crops make slow growth, and often cost great labour to remove them, and sometimes they destroy the crop entirely. The usual way to destroy these weeds is to kill the surface runners by hoeing, and to weaken the roots in the subsoil by deep cultivation. It is often called Bindweed, and is found winding its tough and curling stems around the corn stalks, and also taking fast hold of Beans and Peas, to the serious injury of the crops.

The plants called Crowfoots, of which there are many forms, are also known as Buttercups; but the flowers vary in size and shape, although generally of a yellow colour. All Crowfoots contain much acidity, and are disliked by cattle on that account, whether they grow on arable or pasture land, but especially the latter, as dairy cows often yield milk which is injuriously affected by it. These weeds in Grass land have such a strong hold on the subsoil that they cannot be destroyed except by breaking up the soil and cultivating, which we have done in some instances; but upon strong land they are sure to appear again after a few years. Upon arable land, too, they grow strongly, and the only means

of destroying them is by cultivation and hoeing, as the varieties found in cultivated land are nearly all propagated by seed. In pastures or park lands the only way to prevent ill effects whilst feeding by dairy cows is to mow them off when in full flower to stop their seeding.

The common Fleabane is a sure indication of a wet barren soil. It flowers in August, and usually grows about a foot or 15 inches in height, with a bright yellow flower, having a star in the centre. Land bearing this plant may be said to be worthless for pasture or tillage, and should be planted with trees.

The Coltsfoot is usually found upon strong cold clay soils, and often blooms in March before the Violet. The blossom appears long before the large grey leaves of the plant; the seed ripens early, and the balls of feathery seed expand and assume the appearance of a Dandelion puff, the wind carrying the seed far and wide; it is therefore desirable to prevent the seeding, as well as to destroy the gross leaves and stems by cutting with a weed hook, which if left alone will often deteriorate, and sometimes destroy any of our farm crops. To destroy the plants in strong land is nearly impossible, and the roots penetrate so deeply into the subsoil that we can only hope to check them by deeply cultivating the land with the subsoil plough.

Thistles next demand our attention, not only on account of the injury they do, but also in consequence of their great diversity in size and habit of growth. The most difficult which we have to contend with is a perennial one, which, although not of a gross habit, is nevertheless very troublesome, because it roots so deeply. On some of our very best loamy soils Thistles are very difficult to contend with, and it has been said that their presence indicates good land; but this is only partly true, for they are found in nearly all soils. To destroy them entirely is out of the question, although they may be weakened by hand-pulling in the autumn and by subsoiling during the latter part of the summer. Under any circumstances they must be cut up with the weed hook, because they hardly ever come forward enough to have their flowerheads pulled off in the same way as Charlock is treated by the weed-eradicating machine. The varieties of Thistles which are propagated only by seed are rather numerous. The Musk Thistle is of the largest size both in height, leaf, and stem, often reaching a height of 6 or 7 feet. Then we have a very dwarf Thistle, about 2 or 3 inches high, found mostly on the chalk downs or thin pastures on the limestone soils. There are others, all of which are derived from seed; and the home farmer will do well to keep his fences trimmed and the Thistles cut whilst in bloom, both in woods and on the roadsides. All the annual varieties yield to the weed hook, which is practically the only means of keeping them down and preventing their seeding. The latter unfortunately is often a hopeless case, because so many of our neighbours do not take the trouble and incur the expense of destroying them.

Our next remarks apply to weeds found on most strong clay soils, which are infested with two kinds of weeds especially—viz., the Black Bent Grass and the annual commonly called Yellow Cress, bearing a yellow flower. In order to destroy these two weeds, which are so injurious to Wheat crops on heavy land, it is necessary to drill the Wheat at 12 inch intervals, so that the horse and hand hoe can both be employed with effect; otherwise in some seasons—especially after a mild winter, when the Wheat comes on early, but on receiving a check it loses colour—these weeds would seriously injure the crop unless it is horse-hoed and hand-hoed. These weeds are indigenous to the soils named, and can only be destroyed when they appear in the way we have indicated.

Upon some of the best heavy loams we find a kind of hedge Grass, for it often originates in the fences, and by neglect takes root in the cultivated land. It is commonly called Onion Grass, because it multiplies and increases underground with numberless bulbous roots; the stems also grow to a great height in the crops. It should never be allowed to seed, but the roots should be forked out of any crop by hand labour whenever it makes its appearance, because if only one bulb or root is left it will greatly increase.

The light lands and hill farms—whether of chalk, sand, or gravel soils—are subject to various weeds, which it will be necessary to name; for besides Charlock, to which we have previously referred, we have the blue-blossomed Bugle, the Poppy or Redweed, the wild Vetch, the Cockle, the wild Parsnip, and the Knapweed upon the chalk and stone soils. All these are annuals arising from seed, but they can only in part be destroyed by the weed-eradicating machine, the remainder by the weed hook. On the sand and gravel soils we have the Corn Marigold, the Henbane Nightshade, the white-blossomed Morgan, and the red-flowered Sorrel. These all indicate that the land is deficient in chalk or lime; it is therefore evident that we may spend much labour in destroy-

ing them every year but in vain, for the only way to prevent a succession of such weeds is to chalk the land and neutralise its acidity. Upon almost every soil we have a number of Grasses and weeds too numerous to mention growing in the hedges, and such weeds as the Hogweed and the Burdock are often found on the tillage land, also wild Mint and Nettles; all these should be treated like the Dock—rooted out and removed. Much of the weeding now required upon farms in general arises from carelessness and neglect of the farmer or his neighbours. Hedges and borders may with advantage be cut and trimmed twice a year—in May and July; and the proceeds, except White Thorns, given to cattle and pigs, answering the double purpose of keeping down weeds and affording food for animals on the farm.

We must here allude to parasitic weeds, such as Dodder, called the Trefoil or Clover Dodder. This is a parasitic plant, the seed of which vegetates in the soil, but produces spiral shoots, which soon wind round neighbouring plants, and then becoming disconnected from the earth derives its sustenance from the juices of the living plants of Clover. In some countries the farmer is actually debarred from cultivating certain plants, as the Dodder will often form a dense network over a whole field, and completely destroy the crops. The only way to avoid the Dodder, it being usually found in foreign seed, is to grow on the home farm all the seed of Clover required, or purchase good home-grown seed, which is generally free from the seeds of this weed.

We must in conclusion, although we have probably omitted noticing in this paper some injurious weeds, refer to such as we find impeding the growth of Grass in the pastures or park lands especially. These may be stated chiefly to consist of Rushes and Hassock Grass. The principal Rushes are the large coarse bunch Rush and the small Rusb. The roots of the latter run underground like those of Couch; the former grows in strong bunched, and will live after the land has been drained, and should therefore be cut up with the turf knife and burnt. The small-running Rush will yield to draining and the application of earth and manure composts. The Hassock Grass is often found on some of the best bullock pastures, but should be cut up and burnt, as they often occupy valuable space upon good pastures.

#### WORK ON THE HOME FARM.

*Horse Labour.*—This will be resumed on the driest soils, such as the chalk hills, the stone brash, sands, and gravels, some time before the strong or flat-lying loams will bear the tread of the horses. Some of the first work which can be done will be ploughing and pressing the two-or-three-year-old grass and Saintfoin leas which are intended for sowing with Oats or drege. On the chalk soils where water grass which runs only on the surface prevails, if ploughing with the skim coulter is carefully done and the turf tucked under the furrow, this grass will decay during the growth of the Oat crop. It is not so upon the sands and gravels containing the white-rooted couch, where the ploughing and pressing cannot be done with advantage except that weed be absent, when the land can be prepared for Peas and other pulse crops. In all these instances the home farmer will notice the benefit which must accrue from the use of the new patent press drill to which we have lately called attention in our notice of agricultural implements and machinery. We desire also to remind farmers of the advantage of mixing Beans with late Peas or winter Vetches for spring seeding, as a crop of one of them may be obtained in the event of attacks of the black or green aphides, as these seldom appear in the same season. The black come in a dry season with east winds, the green usually appear when the west or north west winds prevail. Now is the time to provide seed Potatoes of the early varieties, because they require to be laid out upon floors, so that at planting time they may be taken to the field and set without breaking off the buds, and upon the sand or gravel soils they may be planted at once if the weather continues open and moderately dry. We think these early varieties may be planted upon land in which the dung has been buried under the stetch, and if carefully dibbled in with the setting stick the early sprouted stems are more likely to be preserved than by planting in the furrow before the plough. At the time for early Potato planting the best and newest early sorts which are offered should be taken in small quantities every year, as they are too expensive for planting extensively in the field, unless raised by experimental plots to provide tubers for future use if they prove valuable for the purpose.

*Hand Labour.*—The women may now commence stone-picking on the dry soils upon the young Clovers, Saintfoins, &c., or it may be deferred until the rolling is done, because on the chalk soils we often have to deal with large ragged flints, which the roller does not press into the surface out of the reach of the mowing machine or scythe. In this case we recommend the home farmer to have a good-sized box attached to the frame of the roller, with one or two men or lads to follow picking up these flints and placing them in the box as the roller proceeds in its work, to be emptied when turning at the headland or outside the field.

Shepherds are now fully employed, as the Hampshire down lambs fall daily. Some of the earliest are now forward enough to follow the ewes on to the old leas, where they may have Turnips or Swedes

drawn and strewed over the land for the ewes. As soon as the lambs will eat they should, together with ewes, go into the root land and be allowed to run in advance of the ewes, receiving the best of food; as stock lambs they may have the range of the field, eating off the Swede greens, with good hay in their racks. As soon as they will eat cake it may be advisable for them to have a little in their troughs, especially the wether lambs intended for sale. The dry sheep may now be pushed forward with a full allowance of cake meal mixed with the cut roots in troughs, whether of Turnips, Swedes, or Mangolds. These sheep or, in fact, ewes and lambs, when they are accustomed to be fed in troughs should never be removed on account of wet weather. In case of removal to pasture or old lea ground the sheep become unsettled, and do not thrive so well as when regularly fed in their troughs, removing them on to fresh ground daily. Ewes with lambs should not be removed, for although they may have plenty of food they lose their regular habit of feeding, and probably before they get settled down the weather may become fine and dry.

Feeding live stock with malt should now be well considered by the home farmer, because there is usually a portion of the Barley crop which is thin and not fit for malting purposes as required by the brewers. It may, however, be made into malt for consumption by cattle instead of being sold at a low price in the market. The advantages of this practice are as yet not well defined. We therefore advise farmers who have the opportunity to make it a matter of experiment. When a heavy duty was levied on malt experiments were made, some of which were adverse to it, partially caused by the duty upon the article. We remember when malt and Carrots were used for feeding colts and young horses, particularly in Suffolk, and it was generally admitted that nothing would bring horses for sale into better condition. There is no doubt but that malt may be advantageously used as a flavouring material in admixture with injured hay and straw. It may also be mixed with the food of calves and young lambs as an inducement to them to eat their trough food at the earliest period. In a suckling dairy in which calves are fattened for sale as real malt will prove about the best food that could be given, and also for dairy cows to increase the milk.

#### VARIETIES.

**SALE OF PIGEONS.**—We understand that Mr. John Waters of Belfast has recently sold his entire collection of Jacobins, and has purchased Mr. Salter's stud of Fantails, numbering seventy bird (Whites, Blacks, Blues, and Laced). Mr. Waters thus buys back the greater portion of his own birds sold by him to Mr. Salter a year ago. In the collection are two of the best Black hens known. We wish Mr. Waters success.

— **OCCUPATION FOR WOMEN.**—Madame Lina (from Geneva) of 399, Edgware Road, London, requests us to notice her efforts to make watchmaking a woman's occupation. Our correspondent writes:—"The odds are greatly against me; and although I have succumbed to trade opposition and lost heavily, I am, nevertheless, determined to succeed in my undertaking to make watchmaking a woman's occupation, or perish in the attempt." A woman so earnest in benefiting her class deserves encouragement and success.

— **DEATH OF A WELL-KNOWN BRAHMA HEN.**—We regret to hear that Mr. Norris has recently lost his beautifully pencilled Dark Brahma hen. This bird, which was bred by Mr. Garner and was for some time in the yards of Miss E. Shuter, was a model in colour and pencilling. It failed a little in shape and foot feather, but even so it was a very strong bird in the pen.

— **AMERICAN FOOD PRODUCTS.**—The exports of beef from America in 1880 have been computed by the "American Cultivator" at 20,500,000 lbs., mostly going to England. A feature of the trade in cattle has been the large increase in the production in Montana, where the business of cattle-raising is being developed more rapidly than in any other part of the United States. But the largest and most notable increase has been in breadstuffs. The shipments of corn and Wheat aggregate fully 15,000,000 bushels, against 12,000,000 bushels in 1879; and the shipments of flour aggregate 1,100,000 barrels, against 250,000 barrels in the previous year.

— **AMERICAN BUTTER, CHEESE, AND EGGS.**—Of butter some 146,000 packages have been exported, and of cheese 169,000 packages have been sent across the water. These figures show a large increase both in receipts and exports compared with 1879. It is the universal testimony of dealers that the finest grades of butter have met with quick sales all through the year, but poor grades have had a hard time of it in fulfilling their mission, whatever that might be. Com-

pared with previous years the receipts of first-class butter have been in larger proportion, thus showing that butter makers are more fully appreciating the imperative importance of sending only a really good article to market for family use. The increased production of oleomargarine may have had some influence upon the butter market in regulating its demand or volume consumed; but we are assured that such is the increased opposition to the "stuff," that now nobody who has any respect for their taste or stomach will use oleomargarine if they know it. The receipts of eggs have also shown a material increase over the previous year, the return being for 1880 177,000 cases, 22,000 barrels, and 29,000 boxes, against 135,000 cases, 16,000 barrels, and 25,000 boxes in 1879. Prices of eggs have declined of late on account of increased receipts.

— "FLOODS: THEIR CAUSES, MITIGATION, AND CURE," is the title of a pamphlet received, by "AQUARIUS," and published by Fletcher & Son, Norwich. Referring to the greater prevalence of floods now than in earlier periods, the author observes with some force that "When the surface of the country was covered with primæval forest, the bulk of that part of water produced by rainfall which reached the streams reached them by very much slower processes than it does now. First, the foliage and branches of tall trees had to be wetted, then the lower-growing vegetation underneath, both of which would hold a large amount of water in suspension; next, a considerable thickness of decayed and decaying vegetable matter, holding water like a sponge, and parting with it very slowly to the brooks and rivers. But when trees were cut down and forests cleared, and when so many thousands of acres of land in the watersheds of our rivers are covered by the roofs of rain-proof buildings, by paved footways, streets, and roads, and when wet lands are carefully and thoroughly drained, the water has no sooner fallen than it is hurried on to the brooks and rivers as quickly as troughs, pipes, gutters, sewers, and drains can carry it; thus causing an overflow, frequently with very disastrous results."

### POULTRY AND PIGEONS

#### EGGS IN WINTER.

SEVERAL correspondents have written to us asking for some additional information to supplement that contained in "FANNY FIELD'S" letter which we published a fortnight since. It is rather late in the season to say much upon the subject now, but a few plain directions may even yet be of use, and we trust our readers will bear our hints in mind and be prepared in good time for next winter.

In the first place a comfortable house, warm without being overheated, well ventilated without being draughty, and thoroughly dry under foot, is indispensable. To secure the necessary warmth a southern aspect may be chosen, or the house may be built against the chimney or flue of a greenhouse or stable, or some simple heating apparatus may be used in very cold weather. Care must be taken, however, that the house is not overheated. Nothing is more fatal to birds than a sudden transition from great heat to cold. We lost a valuable bird a short time since from a chill which he caught on removal on a frosty day from an exhibition pen in the kitchen to his run. The heating power should therefore only be sufficient to exclude frost in severe weather, and the heat should not be raised over 60° at any time.

Ventilation presents no great difficulty. The birds should have a house of sufficient size to allow them about 10 cubic feet of air space each. Three sides of the house should be perfectly airtight; on the fourth side there should be an opening near the bottom to admit fresh air. The open space at the foot of the door, or the small door for the ingress and egress of the birds, is generally sufficient for this purpose. Then near the roof there should be another opening to allow the foul air to escape. It is as well to make this so that it can be kept partly closed in severe weather and very open in summer. A good glazed window on the south side of the house is an important point, as the birds will not resort to their house in the daytime unless it be well lighted. Sheds are all very well in summer, but in winter a well-ventilated house is a more comfortable place than an open shed.

Dryness of the floor of the house can only be secured by having

the roof perfectly watertight, having the floor raised some inches above the outside ground level, and paying great attention to cleanliness. Earth or ashes make the best floor; and if it be not convenient to have the droppings removed every day, the ground under the roost may, with advantage, be strewn with the ashes from the house every morning. But a thorough cleansing of the house at least once a week is indispensable. Insect pests must be kept in check by the free use of paraffin, lime, &c.

So much for the houses, next as to the stock. For laying purposes no bird over two and a half years old should be kept, and a fair proportion, say one-half, of the stock should be March or April-hatched pullets of the year. For winter laying, hatching so early as January or February is, we find, a mistake, as the pullets commence to lay in September and then moult with the old hens. March or April-hatched pullets, if well fed and of a good laying sort, should commence to lay in October or November at latest, and lay off and on through the winter. The expression "good laying sort," brings us to the question, What breed of fowl it is best to keep. As to this, each person must judge for him or herself which breed is most suitable for their situation and circumstances. As regards laying, the main point to be attended to is that the birds are selected simply for their laying qualities without regard to fancy points. Procure the best laying strain that can be had to start with, and then set only from the best layers mated with cocks of a good laying strain. Slight in-breeding will do no harm, but anything like close in-breeding must be avoided. Crosses between good laying strains of different breeds often produce wonderful layers. We shall be glad to hear from our readers the results of their experience in this respect. We have found the following crosses very advantageous. (1), A Dorking cock mated with Brahma hens; (2), a Spanish or Minorca or Leghorn cock mated with Brahma hens; (3), a Brahma cock mated with Houdan hens; (4), a Game cock mated with Brahma hens. Even if the laying properties of a strain have been lost by breeding for exhibition, a cross will often bring them out as strongly as ever again.

The last point to which we desire to draw attention is feeding. In winter the birds should have their first meal of soft food given warm, not hot. Any good meal or pollard (otherwise middlings) mixed with boiling water is best. If Indian meal is used it requires cooking for a short time. As a rule we do not recommend the use of Indian meal for Asiatics, as being too fattening, but in severe weather it may be used with advantage on account of its great heat-giving properties. In the middle of the day a small feed consisting of scraps from the house and a little meat of some sort may be given. A feed of sound good grain at night completes the list. The meal should be mixed well, so as to be of a dry consistency, not soft or sloppy. We have named no particular meal or grain, as all should be given in turn. Birds, like human beings, are the better of a change of food. The mixtures of different grain sold by corn-dealers should be carefully avoided, as by giving all sorts at once a change is rendered impracticable. An abundance of green food is necessary. A plentiful supply of pure water is of as much importance as good feeding, and should by no means be neglected.

One final word as to the quantity of food to be given. The appetites of birds vary so much that no rule can be laid down as to this. The only safe method is to take care that no food is ever left lying about uneaten, and to handle the birds occasionally to see that they are in moderately good condition—neither very fat nor very thin. We have now done our best to inform our readers as to the means of having eggs in winter, and can only add that "FANNY FIELD'S" hints as to personal attention must not be neglected. Fowls, like anything else, will not pay if neglected. If properly cared for they will generally yield a fair return.

#### POULTRY EXPERIENCES.

I ONCE again send you an account of my poultry experiences, which, I think, tend to prove that Dark Brahmas are by no means profitable as far as the production of eggs is concerned; they are great eaters, are constantly becoming broody, laying from eighteen to twenty eggs and then want to sit, and are certainly, as far as my experience goes, not the breed to keep where eggs are wanted. I shall be very pleased if any of your many readers can from their own experience satisfactorily prove the contrary; for my part, after keeping them for three years, I gave them up. I have invested in a Houdan cockerel, and I intend to breed a cross between him and the Dark Brahma hens. I shall, I think, obtain a fowl with less tendency to sit, and therefore more disposed to lay, and, I believe, of better quality for table.

I have not been so much troubled with feather-eating this past year. Whenever I have observed any disposition that way amongst

the fowls I have mixed flowers of sulphur with the soft food, from two to three tablespoonfuls, and I have certainly found that an efficient remedy, and I would advise anyone who is troubled with the feather-eating disease in their yards to try the sulphur remedy.

My only mishap was the loss of one hen, and as I thought the circumstances under which she died rather peculiar I will narrate them. This hen had been sitting on a dozen eggs for nearly her full time of three weeks, but after the first ten days she refused food; on the twentieth day I found she had scarcely any heat in her body, the eggs were also chilled. I put the eggs in a bucket of hot water, and then placed them under another hen that I happened to have broody at the time; the next day I had five chicks hatched. The hen died a few days afterwards, and a post-mortem examination revealed a broken egg inside her, which of course had been the cause of death.

#### RESULTS.

	Eggs.	Hens.	Eggs set.	Chickens hatched.	Chickens reared.	Pullets.	Remarks.
January .....	114	16					2 Dark Brahma cocks.
February .....	85	16					
March .....	284	15	48				1 hen died
April .....	146	14	11	34	34		1 hen sold
May .....	179	14		11	10		44 chickens reared to maturity, of which 20 were pullets and 24 cockerels.
June .....	157	14					
July .....	136	14					
August .....	133	14					
September .....	71	14					8 hens sold.
October .....	10	6				20	
November .....	35	6				20	1 pullet sold.
December .....	50	6				19	
Total .....	1430						

RECEIPTS.	£	s.	d.	EXPENDITURE.	£	s.	d.
348 eggs sold .....	2	1	10	Value of 19 birds in stock } on 1st January, 1880 .. }	3	16	0

—F. C. TAYLOR.

#### WOLVERHAMPTON SHOW.

THIS event, which closes the show season with considerable éclat, and is, perhaps, one of the most important of the year, came off on Friday, Saturday, and Monday last. The entries were numerous even for Wolverhampton: poultry exclusive of selling classes numbered nearly 600, while Pigeons were 370 strong. The quality in both cases was quite up to former years. The arrangements were on the whole very good. Mr. Lane judged the Game and Game Bantams; Mr. Cresswell the Brahmas, Cochins, and Dorkings; while Mr. Dixon took the rest of the poultry. Mr. Hutton judged the Pigeons.

There was considerable alarm felt for a short time on the evening before the Show owing to some of the empty baskets becoming ignited through contact with a gas jet. Fortunately the mischief was discovered in time, and by the presence of mind and prompt exertions of some of the officials the flames were extinguished before they had gained much strength. One or two baskets were entirely consumed and many damaged, but the building and birds did not suffer at all.

GAME.—Any Variety Cocks (ten) were an exceptionally good class. First and cup for the Game classes went to Mr. Jenkins's champion Brown Red, extra bright in colour, good in head and eye, very fine in tail, said by Mr. Lane to be the best Brown Red he has seen for years. Second (Matthew) a Black Red, extra good in colour, very good in head, eye rather full in hackle, with a well-carried tail. Third (Brierley) a very good Brown Red with a very fine head, and good colour. Fourth (Martin) a Brown Red again, dark in colour, well laced on breast, good in style; rightly placed after the winner here. How he came to be placed above him at Liverpool we cannot understand; h.c. (Beck) a very good Black Red. Black Red Cockerels (twenty-five) were a good class. First (Matthew) very good in style, hard and close in feather, but shot on wing bars; we should have placed him behind second and third. Second (Walters) a very stylish chicken, good in head, a shade dark in colour, a trifle heavy in tail. Third (Jenkins) a very stylish reachy chicken, grand in colour and exceptionally short in feather. Fourth (Staveley) a very stylish chicken, dark in colour; h.c., Forsyth, Capon, Gibbs, Carless, Doyle; c., Jeffries, Mynors, Fletcher, Forsyth. Brown Red Cockerels (fourteen).—A very good class. First (Mather) extra good in colour and stylish, with a good head and eye. Second (Wilson) very well laced on breast, but much too heavy in feather. Third (Dance) a very reachy stylish chicken, extra well laced on breast, rather short in head, and a shade full in feather. Fourth (Bond) very stylish, a shade dark in colour, fine in tail and head, well placed; h.c. (Matthew), the best shade of lemon in the class; h.c., Warner, Fludger, Parker, Matthew. Any Other Variety Cockerels (ten).—A very good class. First (Staveley) a Duckwing, very good in colour and style, rather short in head, and full enough in tail. Second (Phillips) a Duckwing, better in style, head, and tail, but deficient in colour. Third (Mather) a coarse yellow-legged Pile, very much splashed on breast. Fourth (Jenkins) a Duckwing, perfection in colour, style, and head, but too heavy in feather; c., Phillips, Brown Red Hens, any age (fifteen).—The best class we have seen this year. First (Fludger) an almost perfect hen. Second (Matthew), the second Birmingham hen. Third (Brierley) a hen again, the best in class for colour, hackle and tail; only wants size to be first-class. Fourth (Dance) we thought an error, being much inferior to v.h.c. 70 (Matthew) a first-rate hen with a slightly twisted hackle as her only fault; h.c., F. Ward (2), Martin. Any Other Variety Hens,

any age (sixteen).—A very fair class. First (Matthew) a Black Red pullet, extra good in head, very rich in colour, and will make a fine hen. Second (Brierley) a Black Red pullet, better in shape and style, but a shade rusty on wings and slightly defective in head. Third (Horton) a rather coarse Black Red pullet, very full behind and pencilled on wing. Fourth (Staveley) another Black Red pullet, a shade dark in colour, good carriage, with a good head, but too dark in eye, and with a reachy neck; h.c., Capon, Lewis; c., Weeks.

BRAHMAS.—*Dark Cocks* (fifteen) were a very good class. First-and-cup (R. Mitchell) the Hull winner, greatly improved since then; he is now a grand bird, very neat in head, shapely, and of fine size. His faults are hocks, a malformation of beak, and a slightly grizzled hackle. Second (Miss Cotes) good size and shape, with a small but very ugly peaked comb and a little white in sickles, looking quite out of sorts. Third (Comyns) the Cambridge cup cockerel of last year; very shapely, but heavy in comb and hocked. Fourth (Lingwood) a large bird of good colour, ticked on breast and too long in back; v.h.c. (Thomas) a good bird in all other points but deficient in saddle; v.h.c. (Ansdell) white in tail and slightly ticked on sides of breast, otherwise a good bird; h.c., Norris. *Hens* (sixteen) contained most of the noted birds of the year. First, Miss Cotes completed her list of victories with the Palace cup hen. Second (Lingwood) a very large hen, only moderately pencilled on any part, and very mixed in shade on back, heavily hocked. Third (Newnham & Manby) very good in colour but hardly distinct enough in marking; the third Dairy Show pullet of last season we think. Fourth (Comyns) a good-sized hen of the dark type, fairly marked, v.h.c., Percival (the Birmingham winner); h.c., R. Mitchell (the Hull winner); h.c., Comyns, very well marked and clean in colour, but coarse in comb; v.h.c., Kendrick; h.c., Pritchard. *Cockerels* (twenty-four) were for their numbers only moderate in quality. First (Lingwood) one of the Palace team, the fourth we think. Second (F. Bennett) a good-sized bird, wanting in shape, too straight in back and rather coarse in comb, with grizzled hackles. Third (J. Taylor) a neat head, mottled breast, rather wanting in saddle, and heavily hocked. Fourth (F. Bennett) we preferred to second and third; though too straight in back he was very neat in head and had a good black breast; v.h.c. (Comyns, 2) the second and third Cambridge birds, the best in colour and head in the class, but losing through want of size; v.h.c., Birchley; b.c., Norris, Buckston, T. S. Clark, W. Matthews, Turner, Breeze. *Pullets* (twenty-seven) were a very good class. First (Percival) a very clearly pencilled pullet of the light type, with a rather bad comb. Second (Lingwood) more shapely than the winner and shorter in leg, but not so clearly pencilled on breast, a well-feathered bird. Third (Lingwood) of the darker and more heavily marked type, the best Brahma of the three, but a bit mossy on cushion, and that of a Cochins type. Fourth (Mrs. Ward) a rather small well-marked grey pullet; v.h.c. (Comyns), the third Hull pullet; v.h.c., Kendrick; h.c., Comyns, Mrs. Ward, Pritchard; 143 (Norris), the third Canterbury pullet. *Light Cocks* (fourteen) in point of quality a good class. First (Ansdell) the Liverpool winner, again rightly placed first. He is grand in size, shape, and colour, with nice hocks and a fairly good comb. Second (G. H. Wood) good size but narrow, too yellow on saddle, and white in tail. Third (R. Mitchell) the Birmingham winner, here fairly behind first, but might well have stood above second. Fourth, Mr. Percival's well-known winner; b.c., Birch, G. H. Wood, Bigg. *Hens* (thirteen) were, as we have too often seen this season, very bad in colour. First (Horsfall) a good-sized shapely hen, well feathered without hock, but with far too much buff showing through her shoulders. Second (Bloodworth) another shapely one, but showing buff all over. Third (Birch) good in size and shape but defective in colour again, the best of the three in this point. Fourth (Simons) the purest colour in the class, and might well have stood higher; v.h.c., G. H. Wood (2); h.c., Butler, Breeze, Williams; 185 (Mitchell) unnoticed, a well-known winner, now quite overdone, and properly left out. *Cockerels* (nine) were a good class, but rather defective in colour. First (G. H. Wood) good in shape and neat in head, with pure body colour, but too warm in hackle and hocked, the Canterbury winner we think. Second (T. S. Clarke) a moderate bird in most points, with a shocking comb, which should, we think, have displaced him. Third (Howe) very shapely with a neat head and good colour, but a little white in tail; might, we think, have headed the list, but for a buff shade on wing, and as he was should have been second. Fourth (Birch) a rather leggy cockerel of good style with a badly shaped comb but good clear colour; h.c., Tedd, Mrs. Holmes; 199 (Norris) unnoticed, the neatest head in the class and very pure in colour, but rather wanting in depth of breast and foot feather. *Pullets* (eleven) produced some extremely good birds. First-and-cup (T. S. Clarke) a very squarely made shapely pullet of pure colour and fine foot feather, with moderate hocks, perhaps a trifle short in tail. Second (Norris) we thought a mistake, as although of good size and fine shape she was deficient in foot feather. Third (Norris) the Birmingham cup pullet easily second, and pressing closely on first. Fourth (G. H. Wood) another very good well-known pullet; h.c., Tedd, Breeze, Birch, Mrs. Holmes.

COCHIN CHINAS.—*Cinnamon and Buff*.—*Cocks* (eighteen) were a very fine class. First (R. Mitchell) a good-sized shapely Buff cock of medium shade and even colour; hocked. Second (Morris) a very rich Cinnamon cockerel, squarely built, with good feather. Third (Darby) a self-coloured Buff cockerel of medium shade, with heavy feather and hocks. Fourth (C. Brown) a Buff cock of medium shade, with dark shoulders and wings rather in disorder, too straight in back; b.c., Allsopp, Swindell, Nicholls, Tomlinson, Bloodworth, Clatworthy, Hine. *Hens* (sixteen) were another fine class. First (Swindell), the second Birmingham pullet, looking as beautiful as ever. Second (Procter) a beautiful even lemon-coloured hen, as round as a ball. Third (Bloodworth) a hen of perfect Cochins shape and fine feather, but a trifle uneven in colour. Fourth (Tomlinson) a shapely hocked hen, only moderate in colour; v.b.c., Percival (a large, shapely, well-feathered hen, mossy in colour), Mitchell; h.c., Swindell. *Brown and Partridge Cocks* (thirteen) were a very good class. First (R. J. Wood), the sixty guinea cockerel of 1879 looking overdone, and with a little white in tail. Second (Percival) a squarely made bird with grand gloss, not so large as the winner. Third (Tomlinson), another bird of similar stamp, but brown on fluff. Fourth (Clatworthy) a moderate-sized cockerel, nicely feathered, without hock, very neat in head; v.h.c. (Dorrington), good size and colour, but rather straight in back; h.c., Tudman, R. B. Wood. *Hens* (thirteen) were a very good class. The Judge divided the prizes between the two shades of colour. First (C. Brown) a large grouse-coloured bird of good shape and with fine feather, well marked on breast, rather deficient in body marking. Second (Mrs. F. Grant) a grouse colour again, good in size and shape but wanting in marking. Third (R. J. Wood) very well marked indeed, and of great size, but rather wanting in shape. Fourth (R. J. Wood) of medium colour, with moderate markings, good size, and fine leg feather; v.h.c., Percival. *Black Cocks* (fifteen), as also the hens, were in such a bad light that judging or criticism was almost out of the question. First (Toomer) a shapely hocked bird, with fine gloss and neat head. Second (Horsfall) not so neat in head and short of feather. Third (Badger) large but not very shapely. Fourth (Darby) rather small, and wanting in foot feather; v.h.c., Newnham & Smith, Ansdell; h.c., Procter, Turner, Williamson. *Hens* (seventeen) were, as far as we could see, a fine class, failing chiefly in comb. First (Procter) a large shapely hen uneven in comb. Second (Southwell) a shapely hen with good gloss, rather coarse in head. Third (Toomer), the first-

prize Birmingham pullet, in fine condition but comb gone wrong. Fourth (Turner) a nice pullet; v.h.c., Ansdell (perhaps the best in the class, very large, and neat in head); h.c., Cook, Pritchard, Fortey, Mr. Sirgen. *White Cocks* (ten) were a very good class indeed, and we thought it the best we have seen this season. First-and-cup (Chase) a very pure White of grand size, heavy feathered, but hocked, broad in cushion, and with a splendid tail. Second (Darby) another large and extremely good bird. Third (Chase) a good-sized shapely hocked bird. Fourth (Darby) a short-legged squarely made hocked cock; h.c., Mrs. Stevens, Rawnsley. *Hens* (twelve) were also a good class. First (Percival) a neat-headed White pullet of good shape, well fluffed out. Second (Darby) a fine old hen, rather out of sorts. Third (Chase) a very shapely pullet, short of middle toe-feather. Fourth (Darby) an old hen with the same fault; v.h.c., Mrs. Steven; h.c., Ward, Rawnsley.

DORKINGS.—*Coloured, except Silver-Grey*.—*Cocks and Hens* (eleven) were not a remarkable class. First (B. Smith) a good-sized pair; the cock a trifle long in leg, the hen very square and shapely. Second (Peacock) a moderate pair, the cock of the old light shade and too heavy in comb. Third (Pickering) only moderate, the cock with a drooping comb again. Fourth (Countess of Dartmouth) Rosecombs, both coarse in head, and the hen with sooty feet; h.c., Countess of Dartmouth. *Silver-Grey*.—*Cocks and Hens* (seven).—Except the winners, which were a well-known pair, not a remarkable class. First-and-cup (B. Smith) a very good pair of pure silvery colour, the cock slightly splashed on breast. Second (Roe) another clear-coloured pair, the hen wanting in size. Third (Miss Pasley) pure colour again, but rather long in leg and deficient in breast. Fourth (Cheeseman) a moderate pair. *Any Other Variety*.—*Cocks and Hens* (nine) were not at all a strong class. First (Pilgrim) Whites, only moderate in colour, of fair size; the cock rather squirrel-tailed. Second (Countess of Dartmouth) shapely rose-combed Cuckoos. Third (Mrs. Logan) moderate Whites. Fourth (Countess of Dartmouth) Whites, only moderate, the cock being coarse in comb and squirrel-tailed; h.c., Mrs. Walker, Mrs. Logan (Whites).

HOUDANS (nine) were a good class. First (W. Nicholls) of fair size and medium colour, with good crests and muffling. Second (Wingfield-Stratford) larger than first, but hardly so good in points. Third (Mrs. Pattinson) moderate only, the cock squirrel-tailed. Fourth (Thomas) the cock very dark in colour and rough in comb, the hen small but good in quality; h.c., Copplestone, Turner.

GREY-CEURS (six).—Only a moderate class. First (A. Ward) a short-legged pair of fair size, the cock rather heavy in comb, the pullet very good indeed in style. Second (A. E. Ward) a good pair of old birds. Third (Pettie) of medium size, the hen good in crest and muffling. Fourth (Fowler) fair chickens in brilliant condition.

SPANISH.—*Cocks* (thirteen) were by far the best class we have seen this year. First-and-cup (Boulton), face and lobe pure white and nicely spread out, but rather rough and folded. Second (Rawnsley) a long lobe but folded. Third (Boulton) rather a small bird with a nice face and a well-spread-out lobe. Fourth (Bull) a folded lobe again; v.h.c., 378 (Walker) a grand lobed one but squirrel-tailed; 380 (Walker) another fine face but not in order; h.c., Lady Allsopp, Dixon, B. Smith, Walker. *Hens* (twelve) were a very fine class. First (Sillitoe) a pullet with a beautifully smooth long lobe. Second (Street) also had a very good face and lobe. Third (Rawnsley) not so large in lobe, but face of fine quality. Fourth (Street) a large face and lobe but not so smooth; v.h.c., B. Smith, Walker (2); h.c., Lady Allsopp, Street, Andrews.

POLANDS (eleven) were a fine class. First (Rawnsley) Golden, good in size but not in colour of crest. Second (Partington) very fine White-crests. Third (Partington) Golden, the cock with a very large crest. Fourth (Huish) good Silvers; h.c., Mrs. Ricketts (Golden), Rawnsley, and Beldon (Silvers).

LEGHORNS (ten) were a good class; all the prizes went to Browns. First (Gibbs) of good colour, only moderate in lobe, and with rather heavy combs. Second (Bradbury) smart chickens with neat lobes. Third (Hurst) of rich colour and with very good lobes, but the cock with a shocking comb. Fourth (Bradbury) a fine pair; v.h.c., Adams, Sleigh (Brown), Fowler (Cuckoo).

ANDALUSIANS (eight) were not a remarkable lot. First (Simon) neat heads and fair lobes, but colour not very clear. Second (Simon) better in marking but not so clear in lobe. Third (Marchant), and fourth (Stevens) moderate pairs; h.c., Stevens.

MALAYS (eight) were a good class. First (Brooke) dark in colour and of good shape and carriage. Second (Bishop) another good pair of medium colour. Third (Brooke), the cock rather deficient in carriage. Fourth (Draper) a hard-feathered pair of great reach; h.c., Mrs. Bishop, G. Burnell.

HAMBURGS.—*Gold-spangled* (seventeen) were indeed a wonderful class. The Judge said he could have well awarded eight or ten prizes. First-and-cup (Bracewell) a finely-marked pair with good lobes and combs, and in fine condition. Second (Rawnsley) fine colour, very neat lobes, and brilliant condition. Third (May) good in colour and marking, but the cock rather heavy in comb and lobe. Fourth (May) another very smart pair, good in all points; v.h.c., Fielding, Bracewell (2), May, Coultbald, Parsons, Harris, Blakeman; h.c., May, Beldon, were all good pairs, and have nearly all made their mark elsewhere. *Gold-pencilled* (eleven) were not up to the Spangled, but still a good class. First (Fielding) a very smart pair of birds, good in all points. Second (Rawnsley) the cock very clear in lobe and rich in colour, the hen falling a trifle on breast. Third (Beldon) nice lobes and colour, but rather heavy combs. Fourth (Snell) a very good all-round pair; h.c., Rawnsley. *Silver-spangled* (six) were for their numbers wonderfully good, every pen being noticed. First (Rawnsley) a very evenly marked pair, but the cock not quite clear in lobe, and both rather heavy in comb. Second (Fielding) not so good in marking, but better in head properties. Third (Beldon) failed only in lobe. Fourth (Rawnsley) had rather heavy combs; v.h.c., Harris, Ashwell. *Silver-pencilled* (five) were a good class. First (Rawnsley) a very neat evenly marked pair. Second (Beldon), third (Fielding), fourth (Rawnsley) were all good pairs of even quality. *Black* (thirteen) came next to the Golden-spangles in point of quality. First (Rawnsley) good combs and lobes, and in great bloom. Second (Pettie) good in points but out of condition. Third (Copeman) in good bloom, and very neat in head and lobe. Fourth (Pettie) very stylish and fine in lustre; v.h.c., Mayers, Whitehouse; h.c., Fielding, Kilvert (3), Sergeantson.

BANTAMS.—*Game* (sixteen) were an exceptionally good lot. First-and-cup for Bantams (Fletcher) very stylish Black Reds; the cock extra will set up on legs, a shade dark in colour and thick in head, the hen very perfect in colour. Second (Filkin) yellow-legged Piles, the cock perfect in style and tail, colour good but a shade defective in wing ends; the hen a trifle large but very stylish. This pen must have pressed the winner hard. Third (C. D. Jones) Duckwings of fair merit only, and might well have made way for fourth (Fielding), a very good pen of Black Reds; v.h.c., Boddington (Pile); h.c., Mayo and Adams (Black Reds).

SEBRIGHTS (sixteen) were a remarkably good class. First (Lloyd) Silvers, very even in marking except on the cock's tail. Second (Sergeantson) Golden, good in colour and marking. Third (Ansdell) Golden, of very beautiful lacing, but the cock not ben-tailed enough. Fourth (Leno) Silvers, good in marking and tail properties, but the cock uneven in comb; h.c., Bracewell, Leno, Fielding,

Serjeantson, Mrs. Ricketts and Mrs. Evans (all Silvers). *Any Other Variety of Bantam* (fifteen) were a nice collection. First (Phelps) one of the best marked pairs of Cuckoo Bantams we have ever seen. Second (Rawnsley) a very smart pair of Black Rosecombs. Third (Ashley) White Rosecombs, very clear in lobe for the colour. Fourth (Countess of Dartmouth) very neat Japanese; v.h.c., A. A. Clarke (Cuckoo), Osceola; h.c., Phelps, Ludlow, and Pearson (Black Rosecombs); h.c., Cook (Black-booted).

**SILKIES** (eleven) were a fairly good class, not equal to that at Yeovil last week. First (Mrs. Holmes) a very neat pair of Whites, very clear in colour and blue in lobe. Second (Darby) Whites again of fine quality. Third (Darby) Brown Silkies. Fourth (Toomer) White again; h.c., Mrs. Ricketts (White), Darby (Brown).

**ANY VARIETY NOT INCLUDED IN ANY OTHER CLASS** (sixteen) were a fine collection. First (Beldon) a good pair of Sultans. Second (R. B. Wood) a large fine pair of Plymouth Rocks. Third (Miss Mortimer) good Aseels. Fourth (Rawnsley) moderate Sultans; v.h.c., Kilby (Plymouth Rocks), Mrs. Ricketts (Sultans), Bradbury & Adams (Plymouth Rocks), Mrs. Bennett (very fine Langshans).

**DUCKS.**—*Aylesbury or Rouen* (eleven) were a fairly good class. First (Birch) fine Rouens. Second (Harris) good Aylesbury. Third (Partington) Rouens. Fourth (Snell) Aylesbury; h.c., Crofts (Aylesbury), Snell, Bragg, Crofts (Rouen). *Any Other Variety* (fifteen) contained many pens of Pekins, which might well have a separate class. First (Gibbins) Paradise. Second (Serjeantson) Spotted Bills. Third (Nicholls) fine Pekin drakes. Fourth (Yardley) Ruddy Sheldrakes; v.h.c., Nicholls, Birch and Wade (Pekins); h.c., Snell and Simon (Pekins), Leno (Mandarin), Simon (Cayuga), Oakley (West Indian).

#### PIGEONS.

**DRAGOONS** were wonderfully good classes, the competition being very keen. *Blue or Silver Cocks* numbered twenty. First (Close) a Blue. Second (W. Smith) a Silver. Third (Morpus), and fourth (W. Smith), both Blues; v.h.c., Grant and Close (Blues), Morpus (Silver); h.c., Crofts, Carn (2), and Shewell (Blues). *Any Other Colour Cocks* (eighteen).—First-and-cup (Morpus), a fine Yellow. Second (Morpus) a Blue Chequer. Third (Shewell) a Grizzle. Fourth (Elkington) a Red; v.h.c., Hemingsley (2, Blue Chequers), Close (Red), Elkington (Yellow); h.c., W. Smith & Shewell (Blue Chequers), Sparrow (Yellow), Booth and Smith (Grizzles), C. Lomax (Yellow). *Hens, any colour* (thirteen).—First (Booth) a Yellow. Second (Close) a Blue. Third (Elkington) a Blue Chequer. Fourth (W. Smith) a Grizzle; v.h.c., Smith (Blue); h.c., Carn (Blue), Close (Silver). *Cocks bred in 1880* (nineteen).—First (Morpus) a Blue Chequer. Second (same) a Blue. Third (same) a Yellow. Fourth (Grant) a Blue Chequer; v.h.c., Southall and h.c., Smith (both Blues). *Hens bred in 1880* (thirteen).—First (Grant), and second (Elkington) Blues. Third (W. Smith), a Silver. Fourth (Carn) a Blue Chequer; h.c., Smith, Owen, and Morpus (Blues); c., W. H. Peake (a Blue Chequer).

**ANTWERPS** were all remarkably fine classes. *Short-faced Blue, or Blue Chequered Cocks* (eight).—First and second (Hubbard) Blues. Third (Yardley) a Blue Chequer. Fourth (Edwards) a Blue; v.h.c., Blanton (Blue). *Any Other Colour Cocks* (twenty-five).—First and fourth (Saller) Silver Duns. Second and third (Hopwood) a Silver Strawberry and a Silver Dun; v.h.c., Wade (2, Silver Duns); h.c., Moxley, Yardley, Gough, and Blakemore (Silver Duns), Moseley, Plumley, Gough (Strawberries), Buckland, Garfield, Sadler, Edwards, Clulee (Red Chequers), Gardener (2, a Red Chequer and a Silver Dun). *Hens, any colour* (twenty-two).—First-and-cup (Hopwood), second (Wade), third (Sadler), and fourth (Clulee) were all Silver Duns; v.h.c., Smart & Sadler (Silver Duns), Gough (Strawberry), Hopwood (Red Chequer); h.c., Buckland (2), and Gough (Red Chequers), Butler & Lister (Strawberries), Clulee (Silver Dun). *Any Colour Cocks bred in 1880* (twenty-nine) were an extraordinary class. First (Moseley) a Strawberry, second (Chavasse) (2, Gordin), and fourth (Kendrick) were all Silver Duns; v.h.c., Chavasse (2), Gardener & Hopwood (Silver Duns), Yardley, Southall, and Rawnsley (Red Chequers), Sadler (Blue Chequer), Butler (Blue); h.c., Dowler (Blue), Blower & Gough (2, Red Chequers), Sadler, Jerome, Chavasse, Moseley, Green, and Gordin (Silver Dun). *Any Colour Hens bred in 1880* (seventeen).—First (Hopwood), second (Sadler), Silver Duns; third (Hopwood), a Red Chequer; fourth (Chavasse), a Silver Dun; v.h.c., Gough (Blue), Chavasse (Silver Dun); h.c., Dowler (Blue), Oldham, Chavasse, Gordin, and Jerome (Silver Duns), Gough (Red Chequer), Gardener (Blue Chequer); c., Wade & Mrs. Bishop (Red Chequers), Dowler (Blue).

**HOMERS** (twenty-two).—First (Booth), second (Turner), third (Currie), and fourth (Hadley) were all Blue Chequers; v.h.c., Hadley; as also h.c., Leake (2), Currie, Hadley, Margetts, Jenkinson, and c., Leake, were again all Blue Chequers.

**OWLS, ENGLISH.**—*Cocks* (twenty-three), as also the other Owl classes, were of good average quality. First-and-cup (Lister), and second (Weston) were Blues. Third (Weston) a Silver. Fourth (Leake) a Blue; v.h.c., Ingram & Duthie (Blues); h.c., Weston (2), Wardle, Booth (Blues), Branton and Edwards (Silvers). *Hens* (seventeen).—First (Lister) a Silver. Second (Weston), third (Duthie), and fourth (Walker) all Blues; v.h.c. and h.c., Weston (Blues); h.c., Weston and Hammond (Silvers); c., Wardle (Silver).

**TURBITS** (ten) beyond the winner were only an average class. First (Stephenson) a Blue. Second (Yardley) a Silver. Third (Wardle) a Silver. Fourth (Bulley) a Yellow; h.c., Branton (Red), Wareham (Yellow).

**TUMBLERS.**—*Balds or Beards* (eleven) were a wonderful class. All the prizes went to Short-faced, but the Long-faced might have won in their own classes elsewhere. First (Silvester) a Blue Bald with a head as good as that of an Almond. Second (Martin) a Silver Bald. Third (Martin) a Blue Bald. Fourth (Weston) a Blue Beard; v.h.c., Weston (2, both Long-faced, a Red and a Blue Beard), Crofts (a Long-faced Black Bald), Cartwright (2, a Silver and a Blue Bald); h.c., Southall (Blue Beard). *Any Other Variety except Almonds* (seventeen) were an extra good class. First (Yardley) a Long-faced Black Mottle. Second (Crofts) the champion Red Agate, passed over on account of being dirty. Third (Weston) a Red Kite. Fourth (Weston) a Yellow Mottle; v.h.c., Weston (Black Kite), Yardley (Yellow Agate), Goodburn (a Red Kite); h.c., Weston and Mays (Red Rosewings), Langridge (Red Kite), Southall (Muffed Black Mottle), Yardley (Red Mottle), Bocking (Black Mottle), Southall (Muffed Red-breast).

**MAGPIES AND SWALLOWS** (twenty-five) were a fine class; indeed nearly every bird was a well-known winner. First (Tedd) a Black Swallow. Second (Bocking) a Black Magpie. Third (Tedd) a Black Magpie. Equal fourths (Mudie and Bulley) both Red Magpies; v.h.c., Crofts (Red Swallow); h.c., Stevens & Lewis (Black Magpies), Tedd, Branton (Red Magpies), Tedd, Bulley (Yellow Magpies), Bulley; c., Wardle (Black Swallow), Wardle (2, Red Swallows), Mays (Yellow Swallow).

**FANTAILS** (seventeen) were a very good class, but we thought the Judge went rather too much for the English type. All the noticed birds were Whites except the fourth which was a Blue. First, Beldon; second, Warhurst; third, Loversidge; fourth, Yardley; v.h.c., Pecl, Loversidge; h.c., Crofts, Laidlow.

**JACOBS AND NUNS** (seventeen) were nothing wonderful as regards the first-

named variety, but the Nuns were good. First (Bocking) a Yellow Jacobin. Second (Bocking) a Red Jacobin. Third (Crofts) a Black Jacobin. Fourth (Beldon) a Red Jacobin; v.h.c., Weyman & Buchanan (Yellow Jacobins); h.c., Crofts (Red Jacobin), Tatham (Black Jacobin); c., Tatham (Yellow Jacobin), Wardle (Black Nun), Yardley (Red Nun), Beldon, Gould (Red Jacobins).

**ANY OTHER VARIETY** (twenty-six) were a grand collection, the prizes had all to go to the standard varieties, for which there were no separate classes. First-and-cup (Crofts) a Black Pied Pointer. Second (Crofts) a Blue Pied Pointer. Third (Weston) an Almond Tumbler hen. Fourth (Yardley) a Dun Carrier; v.h.c., Chase, Lomax, and Whitehouse (Black Carriers), Yardley; h.c., Weston (2), and Goodburn (Almond Tumblers), Silvester (Satinette), Yardley (Black Mottled Trumpeter), Wilson and Yardley (White Pointers, Martin (Almond Tumbler), Clulee (Black Trumpeters), Lomax (Starling), Keay (Black Barb).

#### OFFICERS OF THE POULTRY CLUB.

PERMIT me to announce through your columns that the election to the vacant offices in the Poultry Club has concluded as follows:—*President*, Hon. and Rev. F. G. Dutton. *Treasurer*, H. R. Dugmore. *Hon. Secretary*, A. Comyns. *Committee*, T. W. Anns, O. E. Cresswell, Rev. H. C. Fellowes, J. C. Fraser, R. E. Horsfall, T. P. Lyon, L. C. C. R. Norris, Rev. J. D. Peake, E. Pritchard, Rev. W. Serjeantson, Butler Smith. Mr. Butler Smith does not wish to serve, and therefore a place on the Committee is vacant, to which the Rev. E. H. Morgan has been nominated. Any other nominations and all the business of the Club should henceforth be addressed to the new Secretary, A. Comyns, Esq., 47, Chancery Lane, London, W.C., and not to myself.—O. ERNEST CRESSWELL.

#### ASEELS AT CAMBRIDGE.

THESE classes, which were specially good, were, in consequence of a mistake on the part of the Show authorities, not judged by Captain Astley on the first day of the Show. We were, therefore, only able to give the awards (which reached us by wire) last week. Colonel Montessoro kindly consented to withdraw his entries—which were among the best—and to judge the birds on the second day of the Show. The following are our notes on these classes:—

*Cocks Any Age* (eighteen).—First (Fellowes) a Mottle bird, looked like last year's winner, a trifle tall, but in good form and having the characteristics of an Aseel; fine skin and face, and good legs and tail; handles well and clear crow. Second (Bryan) a Grey cockerel, a good chicken all over and very hard in hand; will never look better, and may possibly become coarse; the best shaped bird in the class. Third (Dutton) a Red Mottle cockerel, famous back and limbs and well shown. Fourth (Carvill) a White cockerel, clear in feather and face; preferable to the first-prize bird of same colour at Birmingham, being more compact and showing more quality; v.h.c., Bryan (Red Mottle), Gatty (Spangle cock); h.c., Carvill, Mann and Porter; c., Bunnett; 14 (Montessoro) a strongly made Black Mottle of very fine carriage; we thought one of the best in the class. *Hens Any Age* (twenty-one).—The Blacks in this class were decidedly the most attractive. First (Peake) a Black hen, good all round, proper size and style. Second (Dutton) a Black pullet, very beautiful in shape and plumage, somewhat wanting in limb. Third (Dutton) a Brown pullet, very neat and handles well, but wanting in style. Fourth (Bunnett) a Speckled pullet, rather ragged and out of condition, but very promising; v.h.c., Dutton (2, Black), Sugden (Black and White-spangle), Peake (Pheasant); h.c., Mann and Porter, Miles; c., Sugden. Pens 28 and 29 (Col. Montessoro's birds) were both specially good, the first containing a very fine imported Black hen, and the latter another Black, which was perhaps best in the class.

#### OUR LETTER BOX.

**Eggs in Winter (A. D. E.).**—You cannot do better than read the article on this subject on page 121. If you obtain a good breed, and carry out the instructions referred to, you may hope to succeed in your object.

#### METEOROLOGICAL OBSERVATIONS.

#### REMARKS.

30th.—Mild, calm, and showery.  
31st.—Fine, with some bright sunshine.  
1st.—Foggy and colder morning, clear in middle of day, fog again after 3 P.M.  
2nd.—Damp and showery, heavy shower at 3.10 P.M.  
3rd.—Damp, mild, and showery.  
4th.—Slight rain in morning, rest of the day fair but overcast.  
5th.—Rain first part of the morning, fine with sunshine after 11 A.M., windy and rainy after 9 P.M.  
Temperature above the average; that at 9 A.M. has averaged more than 20° higher than the week before last. The means for the three successive weeks have been 21.7°, 30.7°, and 41.9°, an excessive if not unprecedented rise.—G. J. SYMONS

## ROSES ON THEIR OWN ROOTS.

**B**EING but a dwarf in the Rose-growing world, and having only a few hundreds of plants to the thousands possessed by other lovers of the queen of flowers, I almost hesitate to question the decision arrived at by "OXONIAN" (see page 86) on this subject as connected with the National Rose Society, and the list of such Roses as will do well thus started. "OXONIAN" thinks such a list would be "premature." If by that word he would mean imperfect I certainly agree with him, but even an imperfect list would be a great advantage to many, and I cannot but hope that the idea will be acted upon.

"OXONIAN" says, "To produce Roses on their own roots is a very slow process." Well, I cannot help thinking that with many Roses it is much quicker than on the foster parent. What is the process? Take Manetti. Suitable shoots have to be selected, the eyes carefully (and not infrequently carelessly) cut out—this is a great consumption of time—then these are planted close together. The following autumn the cuttings that have grown are taken up and replanted in beds suitable for budding in the following season. Sometimes they are budded the year after planting, but this is not the ordinary plan. Now, take a batch of Rose cuttings. Suitable pieces have to be selected. So far the Manetti and the Rose are equal, but in the latter after the preparation of the base of the cuttings no eyes require removal. This time, therefore, is saved, and the cuttings may be inserted the same as Manettis and left to their fate, and the following season many will bear respectable blooms, and with attention make good plants to transplant in the autumn. It seems to me, therefore, that the process of making a Rose plant "fit for sale" is not so slow as the budding process, and I wonder it is not more adopted.

For some years on a small scale the experiment has been made by me. In 1879 I inserted between four and five hundred Rose cuttings, the greater portion in the autumn, but a quarter perhaps at the spring pruning. Well, last year in the autumn I had nearly fifty plants put out, and quite two-thirds of these were as strong in growth and as vigorous in appearance as the plants I ordered from nurserymen. One or two had made such growth that I was able by careful division to make two plants. These I have planted in two lines by themselves, and I shall be able to compare their flowering with their neighbours.

It is somewhat strange that only two varieties grew amongst the spring-planted cuttings—Hippolyte Jamain and La France ;

and among the autumn-planted cuttings these two varieties also distinguished themselves. Other successful sorts were Charles Lefebvre, Gabriel Tournier, Sophie Fropot, Camille Bernardin, Marie Baumann, and Pierre Notting. I daresay that in my ignorance I am only advancing an idea which every Rose-grower knows, that it is the thornless varieties that are the best in striking from the cuttings. Certainly the great majority of those named above are comparatively free from thorns, and I cannot help thinking that a very thorny stem is against the close fitting of the soil to it when planted, and hence failures occur ; at any rate the close fitting of the soil is essential to success.

I agree with "OXONIAN" as to Maréchal Niel not liking its own roots, and yet there is a sort of exception to this. I say a sort of exception, because I am not certain what the effect would be were the plant cast off to shift for itself. I mean when the long shoots of Maréchal Niel are bent down and layered the growth appears to me more vigorous. I have seen this frequently, and where it can be conveniently arranged I believe it to be the best way of growing that beautiful variety. Neither does in my experience the Maréchal like Manetti as a foster parent, the Briar and Gloire de Dijon stocks seeming to suit it best.

There is no doubt that in deciding on stocks, if we would be successful regard must be had and special attention given to the soil. In a general way it may be said that Teas do not like the Manetti but succeed on the Briar, and, I write hesitatingly, I think they would do on their own roots.

In the case of the Hybrid Perpetuals it is often hard to say on what roots they are. Many budded on the Manetti after three or four years are certainly well established on their own roots and have discarded the foster parent, which is absolutely dead below the point of insertion of the original bud. Such a plant may be said to be growing luxuriantly on the Manetti, whilst the very reverse is the fact.—Y. B. A. Z.

THERE is an exception, it is said, to every rule, and I can adduce an instance in favour of Maréchal Niel thriving admirably on its own roots, notwithstanding the dictum of "OXONIAN," who on page 86 wrote as follows—"Maréchal Niel I am certain will not do well on its own roots." But first I must say that I do not believe the rule thus laid down is established ; yet assuming for the moment that it is, I will submit my exception, and if "OXONIAN" can publish better results from any stock in his possession I will admit my position is weakened.

Last autumn I was at Norris Green near Liverpool, the owner of which, Mrs. Pemberton Heywood, is a great admirer of flowers generally, and Roses, perhaps, particularly ; and Mr. Bardney grows them, especially Teas, under glass probably as well as any private gardener in the kingdom. Now it is curious that the only Rose that this cultivator could not grow satisfactorily was Maréchal Niel. He followed out the notion that it must be "worked," and tried various stocks, but with none could he attain the high standard of excellence that he sought. At length after hearing and reading so much that this grand Rose would not thrive on its own roots, he thought there would be no harm in adding one more to what he thought a long list of failures. He inserted cuttings, which rooted freely, and the plants started so well that he thought they were worth repotting. They were potted and managed similarly to

Gloire de Dijon and other varieties, and at the close of last year no plants in the collection, not even the vigorously growing "old Glory," were finer than those of Maréchal Niel. I think they were in 9 or 10-inch pots (but I write from memory and am open to correction by Mr. Bardney), and there appeared to be two or three growths from the plants, each, say, 20 feet long, of short-jointed, firm, matured wood. I have not a doubt that if tested one of these plants would produce a hundred flowers within three years from the time the cuttings were inserted. They were, if I remember rightly, struck from young wood inserted in sand and placed in a heated pit or propagating house. Mr. Bardney might well say when and in what manner the cuttings were struck and the plants grown that I saw in such splendid condition. That Maréchal Niel will do well as struck from cuttings in the manner indicated I know well, having struck hundreds of plants, which in due time produced hundreds of flowers; but I never saw plants so fine as those referred to, and I am sure the cultivator might usefully detail his practice that has proved so sound and successful.—A. ROSARIAN'S GARDENER.

#### EARLY PEAS.

I READ Mr. Iggliden's able article at pages 85 and 86 on the above subject with much interest, but cannot quite agree with him when he says "that in his opinion late autumn sowing is often a waste of labour and seed," for through the last three severe winters late autumn sowing has proved a success with me, but I know that early autumn sowing followed by severe winters will often be a failure. Early autumn I take to be October; late autumn, November. If sown in the former month, the ground being warm, the seed soon germinates, and the growth is too high above ground to withstand 20° or more of frost, but if sown about the middle or third week in November, the growth, if it appears above ground before very sharp weather sets in, can be more readily protected.

I usually sow about three quarts of Peas on a south border between the 12th and 20th of November, the ground being dug and the seed sown the same day in drills 4 feet apart, and about 4 inches deep, being about 1½ inch deeper than the usual spring and summer sowings. A row of hardy Cos Lettuce is also planted midway between the rows. The weather being open and favourable the young plants made their appearance about the middle of December, and as soon as visible in the rows a draw hoe is taken and a little earth is drawn over, enough to just cover them, as if this is not attended to the birds will destroy them, and if severe weather sets in the frost would probably injure them. About ten days later the young plants could again be easily seen in the rows, when a little more earth was drawn over them, not more than half an inch in depth, and soon after this the hard frost and snow commenced. Between January the 11th and 17th more than 20° was registered each night, and on the morning of the 21st 28° were recorded; but the snow undoubtedly is one of the best protectors to vegetation, and when the snow melted the Peas appeared to have grown a little. At the present time they are about 1½ inch high, and do not appear to have been injured by the weather.

The varieties sown were William I. and Dickson's First and Best, two quarts of the former to one of the latter. William I. appeared above ground a week earlier than First and Best, although sown the same day. Peas sown at this time have with me been usually ready to pick a fortnight earlier than those sown of the same varieties in the open quarters in February. When those sown at that time and in March appear in the rows I draw a little earth over them, as I have found it the best method of protection from birds, but it must be done just when the ground cracks and the tips of the shoots can be seen. If cold east winds prevail so that little growth is made the birds are often so troublesome as to necessitate another covering of earth, but if the wind changes round to the south with warm showers the young plants will quickly shoot through their covering of earth. This method of protection from birds I have found more easy and efficient than white cotton or worsted.

Early Peas I have found will not succeed well if sown on heavy land, the wet in my opinion being more prejudicial to them than the cold. Several good varieties of Peas have been named of late, with selections of vegetable seeds in the Journal, but there is a variety generally well known not brought into notice so much as it deserves to be. It was considered twenty years ago to be one of the best for productiveness and quality, and the same may be said of it at the present time. The variety I refer to is Champion of England. Out of nearly thirty quarts I sowed last year of several varieties this old one was unsurpassed. Of the latest new

and expensive varieties I have had no experience. Two profitable varieties are Auvergne (syn. White Scimitar) and Laxton's Supreme, both from 5 feet in height, but their quality is not so good as Champion. Two good dwarf Marrow Peas of the older varieties are Veitch's Perfection and Yorkshire Hero.—A. HARDING.

#### LILIUMS FROM SEED.

THE following notes on growing and flowering Liliiums from seed are the results of my own experience. I cannot state any fixed time for the plants flowering after the seed is sown, for I believe it varies according to varieties and treatment as regards heat and attention. On November 4th, 1872, a quantity of seed of *Lilium auratum* was gathered, and sown on the following day. The compost used was equal parts of turfy loam, leaf soil, peat, and river sand, adding a small quantity of charcoal. Similar compost was employed until the plants flowered, each year using it a little rougher than before. Moderate-sized pans were filled to within an inch of the rim, and the soil made level. The seed was sown rather thickly, and covered a little more than its own thickness with peat and river sand. The pans were plunged to their rims in ashes in a cold frame, and after nine days watered through a fine rose, and covered thickly with moss and kept moderately moist. Towards the end of July, 1873, the seedlings made their appearance, and in November of the same year a few of the strongest were pricked-off in pans and returned to the cold frame and plunged as before. During the summer of 1874 the pans were stood outside at the back of some pits, and in December the seedlings were transplanted and the pans again plunged in the frame. In the spring of 1875 they were stood outdoors in partial shade, and during summer a few of the plants formed one small flower bud each, but not having sufficient strength the blooms did not expand. The plants remained out until October, when all were transplanted, the largest bulbs being placed in 48-size pots and plunged in a cold frame until March, 1876, when they were taken out and again stood outside, and in July we were rewarded with some fine blooms. Thus, under the cool treatment, it takes three years and eight months to obtain good flowers. I have no doubt that by employing heat and paying close attention to the plants that *L. auratum* can be had in bloom in two years and a half from sowing the seed, as has been stated; still, without doubt the cold treatment is best.

We have *L. giganteum* sown in 1876, and shall expect the plants to bloom in 1883; *L. Humboldtii* sown in 1877, we expect to bloom this year, 1881; *L. pardalinum* sown in 1876, flowered in 1880; *L. dalmaticum* sown in 1878, we shall expect to flower in 1882 or 1883. *L. Kramerii*, sown in 1877, are as yet very small, but may bloom in 1883.

The *L. tigrinum* section and *L. longiflorum* are raised with us by bullets from the stem, and take three to five years to get a good flowering bulb.—THOMAS TAYLOR, *Gardener to J. McIntosh, Esq., Duncevan.*

#### THE USES OF VEGETABLES.

THE practical and suggestive remarks of "WILTSHIRE RECTOR" in the Journal of February 3rd on the vegetable supply, open a wide and important field for discussion.

Whether or not the demand would keep pace with the supply or *vice versa* were fruit trees more extensively planted, time and the future seasons could alone determine. But at least wherever there is suitable and unoccupied ground the experiment might be tried; and the advantages to the owner of possessing garden produce instead of purchasing must be obvious. In fields, pleasure grounds, even in parks, Apple trees are as ornamental as Thorn trees, Walnut trees are stately and fragrant to the touch, whilst Plum and Cherry trees might line our roads as they do so many of the highways in Germany and other Continental States. But vegetables even more than fruits enter into our daily fare, and they would do so still more, as "WILTSHIRE RECTOR" shows, but for prejudice and ignorance as well.

Valuable, almost indispensable, as the Onion is, many persons cannot partake of it owing to its strong and to some repellant flavour; yet were it more generally known that a far more delicate and equally efficacious flavour is to be obtained by scalding or boiling the Onions first in water or skim milk, they might be even more universally used and appreciated.

Jerusalem Artichokes (amongst the lightest and most digestible of vegetables) may be used whole, mashed in fricasees, or in soup (*en purée*). They hardly require cultivation, only room.

In rural districts, unless you grow your own, the supply of vegetables is very uncertain. Here and there you find cottagers sell very fairly, rather under than over the price in market towns,

calculating that it is better to have sure customers at the door rather than risk the expense and loss of time in transit and the precariousness of finding purchasers. Owners of large private gardens do not like the trouble and delay of attending to small consumers, preferring rather to dispose of all spare produce wholesale to the greengrocers. On the other hand, where there is little competition, we often pay more in the country than in a town, not for vegetables only, including Potatoes, but for butter, eggs, and poultry, which, affecting to be ruled by market prices, whatever the quality may be, almost invariably stand at the highest figure touched at the current market day of the week.

That we do not make the most of our vegetables I freely admit. Practical though our national qualities may be, patience, perseverance, and thrift in cooking are not yet characteristic of our kitchens. Most vegetables, except, perhaps, Green Peas and Asparagus, can hardly be too much cooked, and most can readily be used up again. Potatoes, Parsnips, and Carrots are well fitted for the frying-pan when they have first been boiled. Stewed Celery and stewed Cucumber are amongst the *crème de la crème*, and if served with a *souppçon* of good curry powder well blended in the same, might with macaroni make a course of themselves. An excellent pudding may be made of mashed Vegetable Marrow, sweetened and flavoured. In short, it is the will that is wanting. Hard indeed it is to find anything understood but waste. The gathering-up the fragments, the making the most of them for ourselves and others, goes still against the grain of our generous but mistaken English nature. Scientific training has still much to do in teaching just proportions and sounder knowledge.—A. M. B.

#### THUNIAS.

IN most collections of Orchids, however small, at least one species of *Thunia* finds a place, and they all well deserve attention, for if carefully grown they are really handsome plants. All the *Thunias* are natives of the East Indies, consequently they require a moderately high temperature when growing. They are sometimes apt to be disappointing. I have experienced disappointments, and have seen good Orchid growers fail in flowering them satisfactorily some seasons. Each grower no doubt has a special method of growing these plants as with many others that come under his charge, but as it may afford a hint to someone I will state my experience, success, and disappointments.

*Thunias* are, I believe, strictly speaking epiphytes, found growing on the trunks and branches of trees, and should therefore be treated as such. I do not mean by this that they should be grown in baskets or blocks, for undoubtedly they succeed best in pots. They will soon be starting into growth, and should be carefully examined so as not to allow them to remain so long in their winter quarters as to check the young growth. Some gardeners repot their plants annually; others allow them to remain for a couple of seasons in the same pots or pans, the second year only removing a little of the old soil from the surface, and giving a top-dressing of fresh compost. I prefer repotting every season, as *Thunias* are rather strong-rooting plants. I have tried several composts and do not advocate a rich material. Two years ago I potted my plants in good fibry loam, peat, and dung, supplying abundance of liquid manure when they were well established; the result was vigorous growth and no flowers. I never saw finer growths, some of them were between 4 and 5 feet long and nearly an inch in diameter. I was greatly disappointed at this, for I had taken much care with them. Last season I was more successful, treating them somewhat differently, potting them in fibry peat, sphagnum, and plenty of silver sand. The result was short stout growth and plenty of flower; some of the spikes of *T. Marshallii* had as many as eight and nine flowers. When I next pot them it will be in a poorer compost still, employing a fine peat and more sand.

The best time for potting is when the young growths are pushing, using clean pots or pans as the case may be. Drain the pots thoroughly, and over the drainage a thin layer of sphagnum or coarse leaves should be placed, to prevent the finer particles of soil passing into the drainage. Pots of various sizes may be employed—a 48-size pot is suitable for strong plants, and 32's may be used for three plants, placed in the form of a triangle. If good large specimens are aimed at, five or six plants or even more may be placed in a pan. The pots should be filled to within about a couple of inches from the top with the compost. Place the plants in the position they are to occupy, and secure each of them to stakes, then fill in the compost to within half an inch from the top of the pot, and surface with a little chopped sphagnum and silver sand. If the growths are very long it is a good plan to bend them down so as to have them nearer the glass.

They should occupy a light position in the stove, watering rather sparingly till the roots begin to take hold of the soil. After they are well established abundance of water will be necessary—in fact, they should never become dry at the roots when growing. When the flowers are showing the plants will be greatly benefited by occasional supplies of liquid manure until the flowers commence expanding. By removing the plants to a cooler and drier house the flowers remain longer in perfection. After flowering has ceased and growth is finished they should be gradually exposed to the sun to ripen their growths, water also should gradually be withheld. The foliage will soon change colour and ultimately fall off, after which time they may be stored away in any cool house where the temperature does not fall below 45°, keeping them dry until the following spring. *Thunias* are readily propagated by cuttings. Take off the tops of the last-made shoots, insert them in a sandy soil, and place them in bottom heat in spring. All the species of *Thunias* are all worth cultivating, requiring identically the same treatment. *T. Bensoniæ* and *T. Marshallii* are by far the largest and most showy.—W. K.

#### CORREA CARDINALIS.

THE woodcut (fig. 26) represents a small branch of this attractive greenhouse plant, which is generally grown in gardens where

Fig. 26.—*Correa cardinalis*.

the numerous handsome Australian plants are adequately valued. The corollas are tubular, as shown in the figure, an inch or two in length, of a brilliant crimson scarlet hue tipped with green; and as the slightly pendulous flowers are produced singly from the axils of nearly every leaf towards the apex of the shoots, a few specimens of moderate size, say in 48-size pots, are of considerable beauty on the stages of a greenhouse or conservatory during autumn or winter. The plant is not quite so compact as other forms in the genus, therefore a little judicious pruning is required, shortening the long straggling shoots, but with that exception its cultural requirements are similar to most *Correas*. A soil

of turfy loam, peat, and sand, such as is prepared for the majority of allied Rutaceous plants from the southern hemisphere, thorough good drainage, and careful supplies of water are requisite; and with attention to these matters, and ensuring the maturing of the growths in summer, either by placing the plants out of doors on a firm bottom of ashes in a slightly sheltered position where protection can be afforded from heavy rains, or by arranging them in a cool well-ventilated portion of the greenhouse, satisfactory results can be readily obtained.

*Correa cardinalis* was so named by Dr. Ferdinand Mueller, the well-known Australian traveller, who found it in several districts of that continent, particularly Victoria and Gipps' Land. Seeds were sent to Messrs. Veitch at Exeter about 1854, from which plants were raised and distributed.—L.

### THE RESULTS OF HORTICULTURE.

IN our rambles on the south coast we may occasionally meet with *Brassica oleracea*, a small unattractive plant, but of inestimable value on account of its being the parent of a large section of culinary vegetables which have contributed so much towards the health and sustenance of the population. All our fine Cabbages, Cauliflowers, Broccoli, Brussels Sprouts, Scotch Kale, and some Borecoles owe their origin to this little weed. Had not some accidental circumstances brought this plant under the observation of the horticulturist, it might have remained in its native haunts to this day, and we should not have known these indispensable additions to our gardens that we now possess. It is very strange what varied forms have resulted from cultivation, and what a small resemblance some bear to the original: some are quite hardy while others are destroyed by frost, and they have adapted themselves to our requirements in a surprising degree, so that we may have them in season the whole year round. What appears most strange is that these varieties have almost constituted distinct species by retaining the power to reproduce their characters from seed. Most horticultural productions show a tendency to return to the original, but with the Brassicas the inclination is to stray further away and to sport into greater variation. When they are grown in large quantities for seed it is the custom to go over the rows and pull out what are termed rogues, which are those that show a slight variation from those intended for seed, but I fancy if those were planted by themselves some of them might prove useful additions. Every seedsman appears to have a collection of his own, and it is possible we may have something that will differ as much from a Cauliflower or Brussels Sprouts as they differ from the original parent. Although the external form has assumed such varied shapes the internal structure remains the same, as will be seen when in flower; and it may then be said that we do not know a Cabbage from a Cauliflower, and many would not from the flowers alone. In other tribes of plants credit is taken for having obtained crosses, but in the Cabbage tribe it is usually left to Nature; yet something in that way might be done, although it is difficult with all things in the open air, but it deserves attention.

Much may be said on the cultivation of each variety, but it is sufficient to show what great results have been obtained from a comparative insignificant origin. Also I should direct the attention of gardeners to the blanching of vegetables. Many are rendered more palatable and delicate by being blanched, and I think others may be added to our list if experiments are carried out in a judicious manner and proper attention is paid to the subject.—R. C.

### THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 89.)

THE very great significance attaching to the terms "positive" and "negative" render it all-important that the distinctive differences in their contending actions pertaining to the atmosphere should now be fully recognised and comprehended in order to sufficiently realise the results, for as everything in life and growth depends primarily on the contention of these two opposing forces, it is absolutely essential that they should be rightly understood. Their antagonistic powers may be likened to the planting a tree with one hand and pulling it up again with the other, or driving a nail with the face of a hammer and drawing it out again with the tail. For the plant, the positive condition prepares and provides the food, but it is the negative that causes its digestion and appropriation; and should there be any check or cessation in either, so as to destroy the even balance, unhealthiness or even disease becomes the inevitable consequence.

In order that there may yet be no further confusion of terms it will be desirable to restate the attendant results of these separate

conditions of force. It has been observed that every electrified substance is invariably surrounded by an electric state of the opposite character; thus a positive is attended by a negative, and a negative by a positive. Then, again, in the electric decomposition of water, for instance, consisting of one volume of oxygen, which is a negative, to two volumes of hydrogen, and these being positive, the negative oxygen goes to the positive electrode, whilst the positive hydrogen passes to the negative. These consequently were designated by Faraday as "ions," from the verb *eo*, I go—*ions*, going; hence, one class of elements become ions to the positive, whilst the other class are ions to the negative; and in the decomposition of all compound substances whatever, they being composed necessarily of a positive and a negative, this rule is strictly adhered to, each one going to its respective quarters.

It is commonly supposed that plants possess some kind of power that enables them to select their food as if they were endowed with intelligence sufficient to direct them in "what to select and what to avoid." That there is some degree of selection made is perfectly true, but then it is wholly in accordance with this law of electrolysis to which they are helplessly subservient, and most assuredly not by any power of volition on their own part; hence it becomes perfectly easy and certain to be able to predicate the direction in which any particular elements will pass.

With respect to the atmosphere, this is composed of two simple gases—oxygen and nitrogen, together with two other gaseous compounds—carbonic acid and water, the whole being more or less contaminated with soot, fungus spores, and minute particles of dirt of almost every description. It is, however, only the two former gases which constitute the atmospheric air proper, the others being adjuncts, continually varying in their proportions. These, however, are but the "materials" of growth; the "modifying principles," alluded to by Sir Humphry Davy, consist in the atmosphere being charged with electricity.

Unlike water, the gases of which are combined together chemically, the gases of atmospheric air are only mixed together mechanically, so that the least possible degree of attraction is enabled to separate and appropriate the oxygen, as also the nitrogen. The extreme wisdom of this arrangement is manifest in thus providing a starting point, requiring only the smallest possible amount of force to upset that stationary equilibrium which, once disturbed, goes on accumulating in intensity, like the stone rolling down hill, until the highest working power has been attained. Then, in order to secure the breaking-up of the *vis inertiae* of these gases and to acquire the first step in the movement, the electricity of the atmosphere comes in as an indispensable agent. In its normal state the atmosphere is electro-positive, and consequently the earth beneath it is necessarily electro-negative. Now, the immediate consequence of these opposite states is that any substance placed partly in the earth and partly in the air becomes polar by induction, like the wire at page 355, and hence an attracting power is thus imparted to one end to the exclusion of the other, which causes it to seek out and combine with the oxygen chemically, leaving the nitrogen unaffected by its selection. In this chemical combination of elements a further degree of electrical force becomes developed, and this in its turn again leads, by induction, to a still greater measure, and so heaps up a continuous supply as the force becomes utilised in the products of growth. The plant, situate with its roots in the ground and its head in the air, is first dependant on the air and the earth for its primary polarisation, and this again has to depend upon the intensity of the opposition, or amount of polar energy between the earth and the atmosphere. Hence, as dry vegetable matter is a very bad conductor, it is essential in the first place that the texture of the plant should be fairly supplied with moisture. Then as fluids charged with certain salts in solution are much better conductors than plain water, we have in this one means of exciting a more energetic degree of polarity. Following upon this the leaves and stems are made more powerfully attractive of oxygen as the next stage in the process.

Now with respect to the atmosphere. This is continually varying in its intensity as well as in its direction—that is, from positive to negative and back again, and it is to these changes that we have to attribute the many fluctuations and differences of situation, as well as the various abnormal conditions of growth. When the gardener complains of "want of strength in the air," this want of electric energy is one great source of the weakness, if not the principal one. Leave a steel magnet without its soft iron keeper and it soon loses its magnetism; but this may be speedily restored by rubbing it in a certain direction with another magnet. The same loss is ever being experienced by the atmosphere, but here it is renovated in a different manner. It was shown practically on the lecture table by Sir William Grove that

a beam of light produces heat, electricity, magnetism, motion, and chemical action, and hence we have in the sun's rays a most powerful renovator of the earth's atmospheric electricity, as well as of its heat and chemical action, &c. One of the most obvious effects of the sun's polar influence on the leaves of trees is in keeping them constantly with one particular surface upwards, in accordance with the laws of "opposites attracting;" whilst the reverse, or of similar states repelling each other, is as strikingly evidenced in the leaves, branches, and roots avoiding contact and steering clear of one another as if they were endowed with sight and intelligence.

But as the sun's rays have to pass through our atmosphere to reach the earth's surface it will be obvious that the condition of the air it has to penetrate must of necessity exert a material influence upon its results; hence it is that different localities, with their artificial surroundings, have a most important bearing on the present question. It is an essential point that the electrical condition of the atmosphere should be positive; hence any admixture of soot, which is carbon or charcoal, and is a most powerful negative, must have the effect of weakening or counteracting its positive tendency, and thus lessening the required polarity between the earth and its atmosphere. Then, again, in addition to this visible contamination of "blacks" in the air there is, if possible, a more serious evil still arising from our coal fires not at first so readily apparent. On looking at a freshly made up coal fire a flickering flame will be observed playing amidst the smoke as it ascends, and every now and then a jet of intense brightness bursts forth, goes out, and relights again and again; but in these intervals of going out the unignited gas ascends to mix into the atmosphere above and become an invisible cloud, the more solid particles of the soot settling down to the earth or its tenants. The dry outer bark of trees being positive the negative soot is attracted and adheres to the surface, as it does to every other exposed positive—our own skins to wit. Now the combination of carbon with oxygen is heavier than air, but the solution of carbon in hydrogen—as in coal gas—is lighter than the air, and thus maintains itself in a stratum up aloft, whilst the former descends to the earth's surface, and thus becomes suitably situated for being utilised by vegetation. To be convinced of the quantity of carbon thus held in solution and invisible, hold a piece of cold iron, tin, or glass in a gas flame, and it will immediately become coated with soot, which is the precipitated carbon. But the upper invisible stratum of contaminated air escaping from our chimneys will have its negating influence in modifying the sun's rays, hence it is from these facts that in the neighbourhood of smoky districts the air is "not strong enough." Then again, the proximity of buildings tends not only to destroy the polarity of the atmosphere, but they absorb so much of its moisture as to render the air highly siccative instead of being a carrier of moisture to the vegetation.—W. K. BRIDGMAN, *Normich*.

#### HARDY ROSES.

In the "Rosarians' Year Book for 1880" I had a short paper giving the survivors of some beds of exhibition Roses budded some eight years before. The list of sorts will be found by any readers interested in the matter in that volume. Since the paper was written two winters of more than ordinary severity have occurred, and yet some varieties remained alive and healthy. If the sorts seem to you worth recording please give the list which I subjoin.

##### ROSES OF WHICH YOUNG WOOD IS ALIVE ON FEB. 4TH, 1881.

H. Teas.—Cheshunt Hybrid	H.P.—Clotilde Rolland
H.P.—Edward Morren	Duchesse d'Aosta
Caroline de Sansal	François Fontaine
H.C.—Miss Ingram	Camille Bernardin
Paul Verdier	Mad. Clemence Joigneaux
H.P.—Madame Laurent	Emily Laxton
Madame Victor Verdier	Marchioness of Exeter
Abel Grand	Mons. Boncenne
Centifolia Rosea	Princess Mary of Cambridge
Dr. Andry	La France
La Fontaine	Thomas Mills
Mad. Thérèse Lévet	John Hopper
Princess Louise	Duke of Connaught
Maurice Bernardin	

Nearly all the Jules Margottin race stand; the English Roses of real English raising; and amongst dwarfs Dr. Andry, Madame Victor Verdier, Thomas Mills, Maurice Bernardin, and Duke of Connaught.—GEORGE PAUL, *The Old Nurseries, Cheshunt*.

NATIONAL ROSE SOCIETY.—I think that your correspondent, "WYLD SAVAGE," has (see page 87) omitted in the causes of the Society's success one very important one—viz., the manner in which it is officered. The zeal, tact, and judgment of our senior

Secretary, the painstaking and care of our junior Secretary, and the prudence and good management of our Treasurer, clearly show that few societies can boast of such a staff, and I think it is only fair when the success of the Society is spoken of this fact should be recognised.—F.

#### FRENCH AND ENGLISH EXHIBITIONS.

As the season for flower shows is now coming on, and, so far from there being any likelihood of a falling-off in the interest attaching to them, that interest seems rather on the increase—one remarkable proof of that being the announcement of the great Exhibition at Manchester in September with its prize list amounting to nearly £2000—it may not be out of place to again draw attention to a subject which has been often mooted, the great difference between English and French exhibitions; and I do this the rather because a paper has been forwarded to me by the Vice-President of the National Society of Horticulture, giving an account of a remarkable step taken at the Congress of the various Geographical Societies last August, and which endeavours in that thorough way in which the French carry out an idea to combine instruction with pleasure.

It would appear, then, that on the occasion of this Congress of Geographical Societies held at Nancy, the Secretary General of the Geographical Society of the East of France invited the Horticultural Society of Nancy to take part in its proceedings, on the plea of decorating and furnishing the approaches and hall of the Palace of Stanislaus, where the Congress was held, on a plan never before attempted in floral exhibitions. The idea was eagerly taken up by the President of the Horticultural Society, who urged his colleagues to profit by the occasion and give an example of a complete and instructive exhibition. Time did not permit the plan to be carried out as completely as it was wished, but enough was done to draw attention to an entirely novel idea which might be carried out more fully under more favourable conditions. The plan seems to have been to get together a number of the more recent introductions, and to print a catalogue referring to these plants, which occupied 167 pages, giving full particulars of everything relating to the plants. Take as an example of the minute care with which this is done, so characteristic of that attention to detail which is so marked in all French arrangements, the following—

##### CENTRAL AND EASTERN ASIA.

1501. CHAMEROPS FORTUNEI, *Hook.*; Ch. excelsa, *Mart.* (*non Thumb.*).—Hemp Palm. (Palms). Ornamental and industrial (mats, ropes, hats, and waterproof garments).

China and Himalaya, in its natural state, snowy valleys.—*Tche Kiang, Le Père A. David*, 1868.

Cultivated on the eastern coasts of China between 25° and 35° lat.; in the island of Chusan, 30° lat.—*Robert Fortune*. At Peking with protection during winter, and at Canton in gardens without protection.—*Le Père A. David*.

Introduced by Robert Fortune; sent out by the Royal Horticultural Society. In the north-eastern provinces of China. 1843–45, 1853, 1856.

Full-grown specimens presented by M. Crousse, horticulturist at Nancy. Seedlings presented by M. Gallé from seed obtained in the open air at Segrez (Seine et Oise) from plants which had lost in 1870–71 all their leaves, and produced seed in 1878. Leaf presented by M. Gallé, cut from a plant which had lived out of doors with protection during the winter of 1879–80.

When we add that the principal groups were marked in large diagrams, giving a view of the different portions of our continents subdivided into the different regions according to their latitudes and principal productions, and that each plant had its number corresponding to that in the catalogue, it will be seen how much pains were taken to make this portion of the Exhibition full of teaching to all who chose to profit by it. Nor was art forgotten. Vases and bronzes from Japan and China were exhibited to show how the native artists had used their own flowers and fruit to produce that wondrous beauty of form and colouring which has excited the wonder and admiration of artists in this country.

And now is it possible that such a plan could be carried out with any prospect of success in this country? Those who have, like myself, marked the difference between the manner in which exhibitions are conducted in this country and in France may well doubt if it could be so—i.e., Would it be possible to make our exhibitions instructive as well as pleasing to the general public? True, this was a geographical exhibition to which the botanical was simply an adjunct, but it is evidently the idea of M. Joly that this might be applied to horticultural exhibitions. But see how different is the manner of conducting such. There is a deliberation—nay, a solemnity, about the French method which is strangely at variance with their generally received character. The Jury take a whole day to deliberate, and the exhibitions being

open for some days, everything is carefully and minutely examined. With us all is rush—a rush for the exhibitors in the morning to get their exhibits ready; a rush for the judges, who have at most a couple of hours to get through their work; a rush for the visitors, who gallop round the exhibition, and then go forth to listen to the strains of music or to promenade; a rush to get home again at night—much enjoyment all the while, but at the same time an enjoyment that must be got through. And as we like to travel express and get to the end of our journey as fast as possible, so our French neighbours are contented, save on the English frequented lines, to travel deliberately, as if time were no object. This difference makes it doubtful whether the experiment is likely to be tried here; and yet if anywhere Manchester at their great Whitsuntide Show would seem to be the fittest place to try it in. There the Exhibition lasts several days; there thousands of visitors, and many of them from the artisan class, attend; and there is there an indefatigable Secretary who is used to everything of the kind, and whom no exertion seems to tire; and it might possibly be that an attempt of this kind would tend to give a character to our flower shows which would save them from the charge often made against them of being merely a pastime instead of a source of profit and instruction; and botany and horticulture are so inseparably connected that what would influence one would react on the other. The botanical collector coming upon some hitherto unknown treasure does not merely think of the specimen he may prepare for his herbarium, but also of the figure his newly discovered plant may make some day in the stoves and green-houses of England; while he who goes out to collect for such plants as may commercially be useful to his employers often brings home, too, a plant which, though unsuited for this purpose, may yet be very precious in the eyes of botanists. Horticulture has profited by the zeal of botanists and *vice versa*, and in like manner this new idea of our neighbours may equally serve the cause of both. Is it likely to have a trial?—D., *Deal*.

#### CULTIVATION OF GLORIOSA SUPERBA.

ALTHOUGH *Gloriosa superba* has long been grown in English gardens, having been introduced from the East Indies about 1690, it is not nearly so common as it deserves to be. Its culture is extremely simple, and during four or five months of summer a moderate-sized tuber under ordinary treatment will produce hundreds of blooms. It should be in all collections of stove plants, for its quaint appearance and vivid colours are usually highly appreciated; the flowers also remaining fresh a long time when cut, and for specimen glasses for the dinner table I have found it invaluable. The tubers under my charge were imported five years ago from Ceylon, and have since then increased in size and numbers considerably.

Now is a good time to start them into growth, and my mode of procedure is to place a tuber of 5 or 6 inches in length in a 10-inch pot. The compost I have found them to succeed in admirably is good turfy loam, leaf soil, and a little dung from an old spent Mushroom bed with a good proportion of sharp sand. The pots should be carefully drained, as the plants require a plentiful supply of water at their roots when growing freely. In potting I place a little sand under the tubers and bury them 2 inches below the surface. Very little water will be required until growth commences, which is generally about six weeks after potting, they then grow rapidly and must have a plentiful supply.

Gloriosas delight in a good brisk moist heat, such as is afforded by an ordinary stove. Being a climbing plant it will require a support to train it to, and any form of trellis that might be thought desirable will do. I prefer to train them up the rafters of the stove, as in that position they occupy less space, at the same time it affords them a lighter and more airy position—an essential point in their culture in obtaining brightly-coloured flowers. If grown in a dry atmosphere the plant is liable to the attacks of red spider; plenty of atmospheric moisture and good syringing overhead night and morning are the best preventives. When in active growth an application of weak guano water at their roots twice a week will be very beneficial. After flowering they will show signs of going to rest; then gradually withhold water, and when the leaves turn yellow place the pots on their sides and allow them to remain so until next season.—W. JORDAN.

CHRYSANTHEMUM ETHEL.—Among a considerable number of varieties cultivated in the Cambridge Botanic Garden, none have been so particularly remarked and admired as this. It is a Japanese form, not very double, but of the purest white, with the distinctive feature of unusually broad florets. It is valuable for its long-flowering character, being among the first to open, and

now, the end of January, still in bloom. Another also is still in flower, the name of which appears to be Mr. Deleany, a variety of bronze-red colour. Both these are valuable, and were presented to the Garden by Mr. Wm. Bull.—L.

#### VEGETABLE SUPPLY AND CONSUMPTION.

As a housekeeper I am delighted to see this subject being taken up, for it is one that is in urgent need of consideration. If the quantity grown is as great as your correspondents assert, how do they account for the almost prohibitory price? I feel sure vegetables would be eaten if easily procured, fresh, and at a reasonable cost. All people above the really poor consume as much as they can afford or obtain, but they are now dearer in proportion than meat or bread, but cannot take the place of either, and, except Potatoes, are not so satisfying. All servants delight in fruit and vegetables, but mistresses can seldom supply much beyond Potatoes at present prices, for a good dish of Cabbage or Carrots, &c., costs from 9d. to 1s. Middlemen may have something to do with this, but even where they are sold at the stores the price is not much less. It would surely be worth while to bring plenty of cheap fresh vegetables if they are grown within the reach of the miles of respectable houses, where as a rule now they are rarely used for daily consumption. I believe there is some combination amongst the large dealers at Covent Garden to keep up prices and to destroy or keep away all that is beyond the wants of the present green-grocers. It seems to me the only cure would be for some of the large growers to open a store in some central place, say Oxford Street or Regent Street, and sell to customers at wholesale prices or a little above. There is a large store for meat in Oxford Street which failed I believe last year, but it seems well suited for such a purpose and might be combined with the poultry which is now sold there. It really seems sad that quantities of excellent food is daily utterly wasted because it cannot be brought within reach of those who so much need it.—F. R., *West End*.

#### PORTRAITS OF NEW AND NOTABLE PLANTS.

CEREUS FENDLERI.—“This fine *Cereus* is a native of the great Cactus region of the United States, where, according to its author, Dr. Engelmann, it inhabits rocks in alluvial river bottoms from Santa Fé to the Canon of the Rio Grande below El Paso, and from fifty miles east of the Upper Peros westward to Zuni, and the Aztec mountains and the copper mines.”—(*Bot. Mag.*, t. 6533.)

PITCAIRNIA ZEIFOLIA. *Nat. ord.*, Bromeliaceæ.—“This is one of the small number of Pitcairnia from Central America, with broad petioled leaves, large subsessile flowers, large clasping bracts, and seeds conspicuously tailed at both ends, which make up the section *Lamproconus*, published as a genus by Lemaire. Its nearest ally is the New Granadan *P. Funkiana* of A. Dietrich, which was figured under the name of *P. macrocalyx* at tab. 4705 of the “Botanical Magazine.” The present plant, although it has been known for a quarter of a century, has not been figured previously. It was discovered by Warewicz in Guatemala, and we have a fine specimen in the Kew herbarium, gathered by Purdie in the province of Santa Martha in New Granada about 1845. The drawing was made from a plant sent by Dr. Regel, which flowered in the Palm house at Kew in December, 1879.”—(*Ibid.*, t. 6535.)

NYPHÆA TUBEROSA. *Nat. ord.*, Nymphæaceæ.—“*Nymphæa tuberosa* is a native of lakes and slow-running waters in the north-eastern United States, and may be the plant alluded to by Nuttall as the European *N. alba*, with which it agrees in being nearly scentless. It is described as having the leaves green or yellowish beneath, but in our cultivated specimens they were of a pale dirty purple. The rootstock prolongs indefinitely, but the leaf-bearing tip alone is vigorous, the old part decaying as the new elongates. The tubers, which are 1 to 4 inches long, when fully formed break away from the rootstock, and float about till they are stranded and germinate; they resemble those of the Jerusalem Artichoke, and as many as thirty have been counted on 6 inches of rootstock. In shallow water both leaves and flowers rise high above the surface; in deep water the ripening fruit is drawn to the very bottom by the spiral coiling of the peduncle. Cattle devour the leaves; as do deer, which leave the woods at night to feed on them. The Royal Gardens are indebted to the Botanic Garden of Harvard University, U.S., for tubers, which flowered in July and August.”—(*Ibid.*, t. 6536.)

STATICE TATARICA. *Nat. ord.*, Plumbaginææ.—“With the exception of the Thrift—which is generally consigned to do duty as ‘edgings,’ and a few showy greenhouse species—the genus *Statice* has found little favour of late with cultivators; yet it contains many plants of singular beauty and interest.

Of these the palm must be given to the Canary Island species, introduced by the late M. Bourgeau, which were once the ornaments of a house at Kew devoted to plants loving the dry climate of the south of Europe, but which have long since 'gone out of cultivation,' S. Holfordii, *Hort.*, remaining as almost the only representative of the group. Amongst the south-eastern European ones are many hardy kinds of remarkable beauty, such as the subject of the present plate, whose flowering corymbs (of one plant) form together rounded masses a yard in diameter of delicate sprays studded with ruby-coloured flowers, each set in a silvery calycine cup, than which a prettier floral object cannot well be conceived. It is a native of saline districts in the south-east of Europe, from Dalmatia and Hungary eastward through Bulgaria and S. Russia to the Crimea and Siberia east of the Ural Mountains. S. tatarica was introduced into England in 1731 by Philip Miller, and is described in the first edition of his Dictionary as Limonium 5; it is perfectly hardy, flowers in June and July, and remains long in bloom."—(*Ibid.*, t. 6537.)

LYSIONOTUS SERRATA. *Nat. ord.*, Gesneraceæ.—"The temperate and subtropical regions of the Himalaya Mountains, especially in the eastern division of the range, abound in beautiful species of Gesneraceæ, of which a considerable number have been cultivated at Kew, and some figured in this work; and it is not a little remarkable that this species, which is the most widely distributed and one of the most beautiful of them all, should have so long been a stranger to our gardens. Unfortunately these Gesneraceæ of India are all stove or greenhouse plants, and in the case of the latter the wintering of them requires great care, as they cannot be exposed to the long cold of the English winter, and if put by in a greenhouse they are apt to start into growth too early; many of them, however, and the present in particular, form fleshy rootstocks which will stand a good deal of drought, though none possess such tubers as the American Gesneras, and which render them so easy of culture and of transportation.

"Lysionotus serrata is a native of the subtropical and temperate regions of the Himalaya, from Kumaon in the north-west to Bhotan in the east, inhabiting damp forests at elevations of 5000 to 8000 feet in Sikkim, descending to 2500 in Kumaon; it is also abundant at 4000 feet in the Khasia mountains, and is found on the Karen hills in Burma; its favourite sites are mossy rocks, banks, and old tree-trunks. At Kew it fills a square pan with stems a foot high, and seems quite at home in a subtropical heat, flowering in July and August; and in its native mountains the peduncles are often a foot long, and bear clusters of forty to fifty flowers, of which many open at a time. The plant figured was raised from seed sent by Mr. Gammie, of the Forest Department, Darjeeling. The pale whitish stripe along the nerves of the leaf is not common in the wild state of the plant."—(*Ibid.*, t. 6538.)

#### ASPLENIUM CICUTARIUM.

AMONGST the most numerous occupants of our warm ferneries I think none better deserves the attention of cultivators than *A. cicutarium*. It appears to be a comparatively scarce plant. Why this should be so is not easy to understand, for it is without doubt one of the most elegant of all cultivated Ferns. It has a rather wide geographical range, being found in tropical America from Cuba and Mexico to Peru, Abyssinia, and the coast of Guiana. It is of easy culture, and should find a place in every collection of Ferns however small. Where plants are grown for dinner-table decoration this species should be grown in quantity, for it is very suitable for that purpose, being exceedingly light and graceful in habit. The fronds attain the length of between a foot and 18 inches, and from 4 to 6 inches broad, with ten to fifteen pinnæ on each side. The lower ones are 2 to 3 inches long and about an inch broad, cut down to the rachis into numerous ovate rhomboidal pinnules, which are about half an inch long and about a quarter of an inch broad, obliquely truncate on the lower side, and cut down to the rachis throughout into linear or oblong segments, which are once or twice cleft at the apex. The rachis is compressed and often winged; the fronds are a bright green colour. It grows very rapidly in a mixture of fibry loam,

peat, and sand, with good drainage and a liberal supply of water at the roots.—A FERN GROWER

#### RHODODENDRON JASMINIFLORUM.

THE beautiful race of hybrid Rhododendrons so admirably adapted for cultivation in a warm greenhouse or cool stove, which have been produced by crossing the above-named species with several others, renders it of considerable interest apart from its own intrinsic merit. But as a decorative plant it is only surpassed by some of its progeny, and it is consequently a great favourite wherever it is grown. When a plant of moderate size is bearing several trusses of its pure white fragrant flowers it is simply charming. Such a specimen recently attracted my attention at Messrs. Veitch's Chelsea nursery, where it was flowering in company with several of the handsome forms raised by Mr. Taylor, and among which the one bearing his name was especially noteworthy for the size of the flowerhead and the delicacy of the tint.

The accompanying cut (fig. 27) represents a truss of flowers of *R. jasminiflorum* about the average size, the form of the corolla

Fig. 27.—*Rhododendron jasminiflorum*.

being also well shown. The species is a native of Malacca, where it was found by Mr. T. Lobb, growing at an elevation of 5000 feet upon Mount Ophir, whence it was sent to Messrs. Veitch by that traveller thirty-two years ago. The species that have been chiefly employed with this in raising the various crosses are *R. javanicum*, *R. Lobbii*, and *R. Brookeanum*.—L. C.

THE FRENCH VINTAGE.—It appears that, notwithstanding the injury done to many vineyards during the exceptionally severe winter of 1879-80, the French wine crop for 1880 showed an increase of ninety million gallons over that of the previous year, the total of the vintage being nearly 675,000,000 gallons. In the districts which have not been materially affected by the phylloxera, such as the departments of the Aude and the Haute-Garonne, the vintage was above the average of the last ten years (1,170,000,000 gallons); but in the two departments of the Charente, where the best brandy is made, in the Lot-et-Garonne, and in several others, the ravages of the phylloxera have brought the total down to the lowest point which it has ever reached. During the last ten years the exports of wine from France have varied between 90,000,000 and 63,000,000 gallons; but it should be added that during the same period the imports have been steadily rising from 2,857,000 to 67,500,000 gallons. The departments which produced the largest quantities of wine last year were the Hérault (112,000,000 gallons), the Aude (101,000,000 gallons), the Cha-

rente Inférieure (42,000,000 gallons), the Pyrénées-Orientales (39,000,000 gallons), the Gironde (37,000,000 gallons), the Gers (28,000,000 gallons), the Haute-Garonne (23,000,000 gallons), the Tarn (22,000,000 gallons), the Vienne (20,000,000 gallons), the Charente (19,000,000 gallons), the Côte-d'Or (16,500,000 gallons), the Lot-et-Garonne (15,000,000 gallons), the Saône-et-Loire (14,500,000 gallons), and the Tarn-et-Garonne (9,000,000 gallons). The department which made the least wine was the Creuse (1,800), and there were ten which have no Vines at all, these latter being the departments in which the most cider is made. The total cider crop for the past year was 100,500,000 gallons, this being little more than a third of the average yield for the past ten years, the Apple crop having been a failure in nearly every part of France. Normandy and Brittany are the principal cider-making districts, the departments which stand at the head of the list being the Isle-et-Vilaine (23,000,000 gallons), the Mayenne (18,000,000 gallons), the Seine-Inférieure (13,500,000 gallons), the Calvados (10,500,000 gallons), the Morbihan (9,000,000 gallons), and the Manche (8,500,000 gallons).

#### HIPPEASTRUM PARDINUM.

THIS fine bulbous plant was introduced by Messrs. Veitch from Peru through their collector Mr. Pearce, and it received a first-class certificate in 1867 from the Royal Horticultural Society. It is very distinct, differing from most Amaryllises in the flower having a very short tube, and in the petals spreading out flat. They are cream-coloured, with small and crimson-red spots. The flowers are about 6 inches in diameter, the scape being 12 inches in height and bearing two flowers. It is evergreen. Bulbs in 6-inch pots are now flowering, having in most instances two scapes each, and bulbs in 5-inch pots have also been flowering since December. Plants in 7-inch pots have larger bulbs and throw stronger scapes, but there is little gained by much pot room for this class of plants. I have had it flower from September to April.

It does well in a cool stove, having a position near the glass with a plentiful supply of water during growth, and liquid manure occasionally, the soil being also kept moist even when the plant is at rest. Potting is best attended to between flowering and starting into growth, removing all the offsets, which if potted and grown-on will make flowering plants in two or three years. Turfy yellow loam is the most suitable compost, adding a little leaf soil and a sprinkling of sand. Good drainage is essential.—G. ABBEY.

Mr. T. LAXTON writes as follows relative to the EARLIEST OF ALL PEAS:—"In reply to the inquiry at p. 118 of the Journal, I may state that this Pea is not yet in commerce, but will be thoroughly tested again this year by competent authorities, and if it bears out the opinion I have formed of it, it will probably be distributed next season. It is dwarfier and more constant than Harbinger, and has proved itself at Girtford to be really what its name implies—the earliest of all Peas. It was raised by crossing Ringleader with the pollen of Little Gem, Harbinger being the produce of a cross between Ringleader (or Dillstonc's) and Alpha."

— THE following ROSE SHOW FIXTURES are announced—Royal Horticultural Society, June 28th; Farningham Rose Society, June 29th; Canterbury Rose Society, June 30th; National Rose Society, July 2nd; Reigate Rose Society, July 5th; National Rose Society, Sheffield, July 14th; Wirral Rose Society, July 16th; Sutton Coldfield, July 22nd.

— THE handsome specimen of a most distinct and stately Palm from the South Sea Islands, PRITCHARDIA GRANDIS, in the Anerley Nursery of the General Horticultural Company, produced its flowers last week for the first time in this country, and we are informed that a drawing has been taken for the "Botanical Magazine." The specimen is said to be the only one in England,

and it is certainly the finest, as it is one of the two plants originally possessed by Mr. W. Bull, the other having died. It was exhibited by that nurseryman at the June Show of the Royal Horticultural Society in 1873, when a first-class certificate was awarded for it, and a description appeared in the "Gardeners' Year Book" for the following year. The leaves are nearly orbicular, very regularly jagged or cut at the margin, and they are about a yard in diameter, on petioles of moderate length. The habit of the Palm is particularly noble, and smaller specimens would be very useful for the stove, as the regular fringed edge of the leaves imparts a most distinct appearance to the plant.

— IN a recent number of the "Pharmaceutical Journal" Dr. John Harley relates the particulars of experiments undertaken to prove that FOOLS' PARSLEY (*ÆTHUSA CYNAPIUM*) IS NOT POISONOUS. It appears as the result of these that this plant, which is commonly reputed to be very poisonous, so far from having an injurious effect upon human beings, may even be beneficially employed as a pot herb; at least Dr. Harley recommends it being used for that purpose, though he observes, "the *Æthusa Cynapium* of Sussex, Kent, Surrey, Essex, and Hertfordshire is not absolutely free from the noxious properties attributed to it."

— AN instance of the EXTENSIVE PLANTING OF TREES is recorded on the Pelham Pillar in Lincolnshire, relative to which we cite the following description from *Notes and Queries* of the 5th inst.—"The following is a copy of the inscription on Pelham's Pillar, situate in the parish of Cabourn near Caistor, Lincolnshire, said to be the highest part of the Earl of Yarborough's estate on the Lincolnshire wolds. The pillar is built of granite, and is about 150 feet in height. There is a room at the top, lighted by four large windows, from which may be seen the German Ocean and extensive views of the surrounding country, north, south, east, and west. The entrance door, which is towards the east, is flanked on either side by huge figures of a lion and lioness. The woods and plantations around add much to the sylvan beauty of the place.

"This Pillar was erected to commemorate the Planting of the Woods by Charles Anderson Pelham, Lord Yarborough, who commenced Planting in 1787, and between that year and 1823 planted on his Property 12,552,700 Trees. The foundation of this Pillar was laid in the year 1840 by his Son, and the building finished by his Grandson in 1849."

The number of trees thus planted yearly during the above period was 348,686.

— AT the recent annual meeting of the READING HORTICULTURAL SOCIETY, Mr. Benyon, the President, in the chair, it was stated that the Society had well maintained the objects for which it was started in 1854—viz., the advancement of horticulture in the town and neighbourhood, and of affording pleasure to a large portion of the public, as evidenced by the two exhibitions held during the year, the unusually large number of visitors and the great success of the shows, which were acknowledged to be the best ever held in Reading, although the prizes offered for competition have not been so large as the Committee could have wished. Only a small favourable balance was announced, owing to expenses incurred in repairing the erections in the abbey grounds. It was proposed that the President, Treasurer, and Committee, with the addition of Messrs. G. W. Palmer, Arthur Hill, E. Jesse, and J. Sydenham, do continue their services during the ensuing year, and that Mr. Geo. W. Webb and Mr. R. D. Catchpool be requested to continue to act as Secretaries, which was duly seconded and carried. It was also announced that classes for Rhododendrons and Pansies would be added to the schedule this year.

— WE clip the following from the *Wiltshire County Mirror* ON CULTIVATING RAILWAY SLOPES—"The South-Western Com-

pany are setting a good example in offering to let the waste land on the slopes of their line for cultivation, and it is hoped that other railway companies will do the same. By this means thousands of acres now unornamental and unprofitable will be turned to good account. In some places they might be made available for garden fruits, and under any circumstances might be utilised for the production of Potatoes and other garden or agricultural produce. It is already done on a very small scale in the neighbourhood of various stations; and there can be little doubt that small farmers, gardeners, and minor railway officials would only be too glad of the opportunity of cultivating these waste lands on favourable terms and to the benefit of all."

— WE have received the schedule of prizes offered by the MASSACHUSETTS HORTICULTURAL SOCIETY for the year 1881, from which we learn that the following amounts will be appropriated as prizes in the department named. For plants and flowers 1500 dols., fruit 950 dols., vegetables 500 dols., gardens and greenhouses 100 dols., or a total of 3050 dols. Seventeen prizes varying in value from 30 to 60 dols. will also be offered for new and meritorious seedling plants, fruits and vegetables. Seven exhibitions will be held during the year—namely, Azaleas and Roses, March the 17th; Pelargoniums, May the 7th; Rhododendrons, June the 4th; Roses and Strawberries, June the 23rd. Autumn Shows, September the 13th to 16th, and October the 1st; Chrysanthemums and Fruit, November the 9th.

— MR. H. C. STEWART, Treasurer to the North Street, Marylebone, Flower Show Committee, sends us a copy of his "HANDY BOOK ON WINDOW GARDENING" (Barrett & Son), a pamphlet of thirty-one pages, containing plain and fairly accurate directions for the management of such plants as cottagers usually grow. It is in three parts, the first being devoted to a consideration of the different soils employed in potting; the second deals with the chief operations—such as propagation, supply of water, and potting; and the third contains brief descriptions of plants suitable for windows.

— THE Annual General Meeting of the FARNINGHAM ROSE AND HORTICULTURAL SOCIETY was held at the Lion Hotel, Farningham, on February 7th, when the report for 1880, showing a balance of £36 4s. 5d., was unanimously adopted, and the officers for the present year elected. The date of the next Exhibition is fixed for June 29th.

— MR. W. ROBERTS writing respecting DAPHNE INDICA IN CORNWALL observes—"The climate of this county seems especially adapted for these lovely winter-flowering plants, so well do they flower and thrive. In the gardens of Sir John St. Aubyn, Bart., M.P., at Trevethoe, Lelant, near Hayle, I recently saw a very good specimen of *Daphne indica rubra* flowering out of doors, and the gardener, Mr. Courtice, informs me that he has gathered flowers from it during the present winter."

— MR. DANIEL HILL, Honorary Secretary of the HARROW HORTICULTURAL SOCIETY, informs us that at a recent meeting of the Committee of this Society the Summer Exhibition was fixed for Tuesday, July 5th, and the Autumn Exhibition for Tuesday, September 20th.

— *Nature* states that the Hamburg firm of C. Woermann has sent Mr. Hermann Soyaux to the French colony of Gaboon in order to try to cultivate the LIBERIAN COFFEE TREE at that place. Soyaux has now been at Gaboon for two years, and has there established the Scibonge farm, which is situated about a day's march inland from the Gaboon River, on the Awandu River, which flows in a north-easterly direction into the Bay of Corisco. He now employs some one hundred negroes. Many thousand Coffee trees have been imported from Liberia, and have been

planted, and experiments have also been made with sowing the beans, so that at the beginning of 1882 the first Coffee harvest is confidently expected. The Hamburg firm supports the undertaking in a most efficient manner by sending engines, implements, &c., and experiments are also pending to introduce and acclimatise horses and mules. Mr. Soyaux makes meteorological observations for the Leipsic Observatory, and natural history collections for the Hamburg Museum.

— A CORRESPONDENT states that in a hurried visit to the gardens at ASHBURNE HOUSE, SUNDERLAND, he noticed that *Chamaedorea graminifolia* was in bloom. The Orchids were exceedingly healthy. The fine conservatory was very bright with bloom; and fine plants of Azaleas Countess Eugène de Kerchove, Madame Van Houtte (splendid), and the mollis section were flowering. The above Mr. Cramont, the able gardener in charge, strongly recommends for forcing. *Rhododendron præcox* was also fine, and seems an excellent plant for midwinter flowering. *Erica melanthera* in 8-inch pots had growths over 18 inches long. But the best feature of all were a grand display of Cyclamens in 5-inch pots, seedlings of 1880, with over fifty flowers each. They had received most simple culture—grown in a Cucumber pit near to the glass, well shaded during summer, fully exposed during autumn to the sun's rays, and then placed in a comparatively cool pit.

— A BEAUTIFUL example of DENDROBIUM HILLI is now flowering in the Orchid House at Kew. It has three racemes 12 to 15 inches in length, and crowded with the delicate creamy yellow flowers. The plant was sent to Kew by Mr. Walter Hill of the Morton Bay Botanic Gardens.

— POTATO CULTURE.—A list of Potatoes representing about six hundred sorts in all, but melted down to about half that number by a process of severe selection, forms a dry but perhaps useful feature of the current number of the "Gardener's Magazine." It suggests the question, Who can want so many? It seems, however, that "Potato fanciers" make an amusement of growing all the sorts they can get hold of. Of these painstaking souls Mr. Shirley Hibberd is a guiding star, and the list he has presented in his paper reflects his light in every possible shade of colour. It is surely time we had some good Potatoes.

### THE HOLLYHOCK.

WHEREVER hardy flowers are grown florists' flowers ought to occupy a foremost place. In truth, as hardy flowers become better known there will be a great number of species discarded which are of no real value to the gardener; so that, as with stove and greenhouse plants, merely the finest will as a rule be grown, and foremost in these selections will always be those plants known as florists' flowers. The decorative value of these plants is also noteworthy. To the amateur florist, who, perhaps, grows only two or three species, that is not of much importance, but to the gardener who has to be a utilitarian it is quite the opposite. There is a point of importance as to the time when these notes are published, which will be always kept in view, and that is to study the time when the culture of a particular plant may be described to the greatest advantage of the readers. It will not be practicable to publish the notes on every flower just at the best time, but as nearly as possible that will be adhered to. For the above reason the Hollyhock has been chosen as the subject, as at this time it can be propagated perhaps as efficiently as at any other season, where there is at least a small stock.

At the commencement I must confess the Hollyhock has failed with me. I will explain why I had succeeded well enough with it, having a few hundreds of flowering plants and a large stock of summer-struck plants from eyes, when one September day I became aware of the unpleasant fact that the *Puccinia malvacearum* had attacked the whole of our stock, and in a very short time every plant was dead. I have not succeeded in forming a stock since. A short note appeared last summer in the Journal stating how I was trying to destroy this fungus, but I failed in obtaining a cutting or an eye without the disease, and had to cut the plants down twice to save them from destruction. The last time the

plants were cut was sufficiently early to enable them to make some growth before being lifted and potted for the winter. The young growths from these will be grafted on roots. Though these plants were purchased as being free from disease, one or two of them were slightly affected; still I had hoped to clean them before planting by removing infected leaves and parts of leaves. But the most peculiar fact in connection with these plants and the fungus was this: I cut every plant down beneath the surface of the soil and drew a little soil over the rootstock of each, and yet, no sooner were the plants in full growth again, than the fungus appeared as strongly as ever. Hollyhocks were grown in several districts last year free from disease, even where the Puccinia was in abundance on the common Mallow. I am having plants from three different localities where the Hollyhock succeeded last year, and hope I may be able to have these fine autumn flowers again in abundance.

At this season the only certain mode of propagation is by grafting the young growths on small pieces of root. I have tried them as cuttings, but it is a slow and uncertain method, and at this date it should not be attempted, as, even if the cuttings root, they would be very late. Root-grafting is a simple and sure method of producing plants. After cutting the growths off the Hollyhocks select as many pieces of roots as may be required, if with active fibres so much the better; then cut the base of the scion quite level across, cut its stem half through  $1\frac{1}{2}$  inch from the base, and cut this vertical section out; cut the piece of root in the same manner to fit closely, and tie with a strand of matting. The roots are better for having been washed, as pieces of soil on the cut surfaces cause trouble which is otherwise easily obviated. Though I recommend  $1\frac{1}{2}$  inch as a good length to cut for splicing, I have often made successful grafts with very small pieces of growths. These require a pin to be run through the rootstock and scion in addition to the matting. The best kind of matting is that from mats in use for protecting frames, as it decays quickly. The grafts must be potted rather deeply. If the pots are plunged in a mild bottom heat and precaution taken that the top heat is very moderate—not over  $50^{\circ}$ —a very speedy junction will be effected. After removing the plants from this frame place them where they can grow slowly, and see that they receive a shift into 6 or 7-inch pots directly the first pot is well filled with roots. Let the compost be a rich one of loam and dung. Do not be in too great a hurry to have the plants into their flowering quarters. By the middle of April all danger of check will be past in most seasons, though it may be equally safe to plant a fortnight earlier.

I do not know any plant which roots so deeply as the Hollyhock: deep cultivation is therefore necessary. In soil already rich I allow 6 inches in depth of manure over the surface of the ground. In addition a spadeful and a half of a compost of equal parts loam and dung, with a little soot and bones added, is placed on the spot each plant is to occupy. Under these conditions Hollyhocks grow uninterruptedly with us until the Puccinia stops them. No other disease troubles them here. Staking is of course a necessity; but I do not insert the permanent stakes at the time of planting, as most writers recommend. There is no necessity for placing a long pole at least 6 feet out of the ground into its position two months or more before it is required.

The summer cultivation is simple enough. In ordinary seasons the roots will find abundant nourishment without watering. In dry seasons watering will be a necessity; but the roots travel straight downwards, and water should therefore be given close to the plant without watering the ground in the spaces between. If you require spikes or flowers for exhibition the tops of the spikes must be pinched off in the first case to the height the flowers are expected to open, which is not very easy to determine; and in the second instance, to give the flowers which are retained the full benefit of the powers of the plant to perfect them, the blooms on the spikes must be thinned out as well, to give every bloom space to develop freely. The plants should be at least 4 feet from each other if in the beds, more if it can be spared; but the plants look better and do equally well in borders amongst other plants. As the blooms fade cut the stems down to within a few inches of the ground. If wanted for stock lift and pot the plants in November, and keep them in a cool house where they can grow slowly, and have growths large enough to propagate by root-grafting in the early part of February.

Cuttings are produced during summer from the base of the plant; these strike freely in cold frames, and even out of doors in a shaded position. The flowerstems may be cut into pieces like the eyes of the Grape Vine and inserted in frames, where they root and grow freely. When propagated from seed the autumn is the best time to sow; if sown in cold frames flowering plants are obtained the following year. I may say that the Hollyhock does perfectly well year after year on the same piece

of ground provided the soil is well manured and cultivated.—  
R. P. BROTHERSTON.

#### MR. JOHN SPENCER.

IN our issue of the 13th ult. we announced the death of this estimable man. To the brief notice of his life given on page 31 we have received what our friend "WILTSHIRE RECTOR" terms "a few additional words by a neighbour of the late John Spencer of Bowood." With this true "word picture" we give the accompanying portrait of Mr. Spencer, also true and life-like, and which we are sure will be acceptable to our readers. In our remarks on page 31 we stated that Mr. Spencer died on the 10th of January, 1881, but omitted to say he was born on the 27th of June, 1809.

PERMIT me, as a near neighbour of the late Mr. Spencer, to say a few words from a Wiltshire, and, may I add, a near personal view. In the Journal of January the 13th there was an extremely good account of our late friend, of which the writer speaks too modestly "as a hurriedly prepared sketch." All I can say is, that such a sketch has all the realisation of a complete picture, yet I would venture to place gently and lovingly my wreath also on the coffin of our friend.

Though neighbours, living within three miles of each other, we had never met until some fifteen years since. Mr. Spencer, a regular reader of this periodical, had noticed some articles by "WILTSHIRE RECTOR," and desiring to make the acquaintance of their writer, made inquiries at head quarters, and, as he told me, he found to his very great surprise that "W. R." was a clergyman in his, the extreme northern part of Wilts. I, too, had heard of Mr. Spencer as a man of science, a successful lecturer, a gardener of renown, the bringer-out of the Bowood Muscat Grape, and a man not only of literary power, but a great and successful man of business—a possessor of that order of trained intellect which is of the greatest value when its owner is placed in a position of high trust. That position Mr. Spencer had as steward to the great and remarkable Lord Lansdowne, and to his son and grandson; and he won more than the respect—the love of his noble employers. Mr. Spencer I met in the old office in Fleet Street, and afterwards again and again in Wiltshire. This Journal brought us together, and the day of our introduction I mark in memory "with a white stone."

John Spencer began life as a gardener, and to the last he had a gardener's heart. He delighted, so it seemed to me, to go back in talk and in thought to horticulture; he loved to admire again the beauty of a flower; and as we tasted fruit together had all a gardener's relish for a garden's production.

It was of course a grand day in his life when the great Marquis gave to him the key of the steward's office. I happen to know that Mr. Spencer undertook the duties of the stewardship with hesitation and fear: but on Lord Lansdowne's side there was no hesitation and no fear. He, an admirable judge of character, knew the man of his choice, and had full confidence in his powers. Twenty years of successful stewardship showed how well and truly Lord Lansdowne estimated the man and his powers.

Every steward of a nobleman has, of course, an exalted position, rays of his master's glory fall as it were upon him—he is "the great man's great man." This always follows, but I claim for John Spencer a position higher than this. When he was, say, at an agricultural dinner he was pointed out as "Spencer of Bowood," not merely as "the Steward at Bowood." He had made in men's minds an independent position apart from the office he held. His hand was grasped warmly by men of science, and rank, and station, not only in London, but even in this somewhat exclusive western county. Next to Paxton and "Capability" Brown he had been the gardener who had achieved the highest social position, and he had done it, not by favour nor by fortune, but by the force of his own brain, and character, and manners.

In person John Spencer was a fine, tall, broad-shouldered Englishman, brown-haired and ruddy, with a forehead high and wide and reaching well over the eyes. Having lost his forelock his fine forehead gained in intellectual look; eyes light-coloured and intelligent; nose fine and long; a mouth in which were both power and kindness, the latter I think predominating. I remember watching his face at a public dinner, he sitting at another table just within pleasant view, and I noticed how his face lighted up in conversation, and I recently saw an engraving of a likeness of him in a shop window which did him full justice. He was a man concerning whom a stranger would say, "Who's that?" and I am told by men of business that whenever he was among men of business his words always carried weight. In his own house he was a charming and chatty companion, a pleasant shower of

Bowood Park sights. He had a warm and gentle heart for the animal world, for his favourite dog, and for every bird that flew. Now he would show me some favourite seedling Pelargoniums, and as evening came on would pet his bantams on their perch. The powerful man with the kind mouth was as gentle to and as fond of his pets as a delicate woman.

Such was John Spencer—a successful man, an able man, and, best of all, a good man, who amid unbelieving men of science was, though a man of science, a devout Christian. A few years since—some two or three—he received his warning in the failure of his health, and had he then retired he might have been alive now and perhaps seen fourscore; but he held on too bravely and died

in harness, for, leaving his home in Wilts one cold day on business for London by the early train, the cold struck in and he never recovered. Would it had been otherwise. Nature gives an old man her warning. If it be obeyed he lives awhile; if it be disobeyed and he works on he soon dies, and hence relatives and friends have at too early a day to mourn the loss—the removal to the better world, of John Spencer of Bowood.—WILTSHIRE RECTOR.

P.S.—I append the following note from the *Derizes Gazette*—“Mr. Spencer came in 1836 to Bowood as head gardener. The gardens, vineries, and pleasure grounds are his monument. In 1861 he succeeded to the vacancy caused by the retirement of Mr

Fig. 28.—MR. JOHN SPENCER.

Phelps, and from his accession to the estate management dates the steady course of improvement which has of late years distinguished the Bowood estate. “I began there,” Mr. Spencer used to say, pointing to three small houses near the old Quemerford turnpike. He would have desired to live a few years longer to see the last bad farmhouse and the last rickety cottage. But this was not to be. This active and energetic man is now no more; but if in one sense his works do follow him, in another they remain to stimulate by their example and remind the living of the dead.”—W. R.

We have only to add that Mr Spencer was buried on Saturday the 25th ult., at Derry Hill, Wilts. He was followed to the grave by the following members of his family:—Mrs. Spencer, his

widow; Mr. Spencer Castle, his nephew; Mrs. F. H. Phillips, his niece; Mr. F. H. Phillips, the Rev. J. M. Hall, and Mrs. David Spencer. The Marquis of Lansdowne, Lord Edmond Fitzmaurice, M.P., the Mayor of Calne, and upwards of one hundred of his oldest friends and principal tenants of the Lansdowne estate personally attended. The service at the church was conducted by the Rev. W. H. Hitchcock, Rector of Derry Hill, and the Rev. Canon Duncan, Vicar of Calne.

AURICULAS AFTER THE LATE SEVERE WEATHER.—These commenced a vigorous growth the moment the late frost ceased. I am now referring to those on stands out of doors, on which

I was anxious to observe the effect of such extreme cold. The pots were frozen hard for at least a fortnight, and except a few specimens of green-edged—which I find much more tender as a class than any other—they now show no indication of having suffered. In a few pots that had been excessively watered before the frost, the expansion thereby caused swelled the soil above the rim, but after the thaw a gentle pressure put plant and soil back again without apparent injury. Plants indoors suffered slightly by having the leaf moisture withdrawn by the frost, which has the same effect as a hot sun or dry March wind on Auriculas. A cautious watering neutralised this. The flowering will, I anticipate, be ten days later this year.—W. J. M., *Clonmel*.

#### KITCHEN GARDEN.

OUTDOOR operations have been impeded by the weather, which at the time of writing is still unfavourable for preparing ground for Onion, Parsnip, and Carrot seed; but no unnecessary delay should be permitted, as the soil of gardens under proper cultivation is so friable as to admit of being worked very soon after the weather has become suitable. Onions, and indeed all root crops, succeed well after Celery, or on ground that has been well manured and deeply stirred. To prevent grubs attacking the plants a dressing of lime, soot, and salt in equal parts may be applied and pointed in at the rate of a peck per rod before sowing the seed, as the mixture is also a good fertiliser. Drills for Onions should be 12 inches asunder, those for Parsnips 15 to 18 inches, and the Early Horn section of Carrots about the same distance as the Onions. The ground for Onions should be rendered firm, treading it well before the drills are made and after the seed is covered. For Parsnips and Carrots the ground should only be moderately firm. Leek seed may be sown in rows 12 to 15 inches distance apart. In the north of England sowing the above may be advantageously deferred for another three weeks. Shallots and Garlic should be planted as soon as possible. If a sowing of Brussels Sprouts, Cauliflower, early varieties of Cabbage, Cabbage and Cos Lettuces have not been made in heat, sow at once on a warm border at the foot of a south wall, coating the seeds with red lead to prevent mice and birds taking the seeds, placing a few inches of fine soil as a bed for the seed, and cover them with similar soil. Lettuce wintered in seed beds, also autumn-sown Onions, can be transplanted into rich soil, filling up blanks in the permanent beds, firming the soil about the roots of those upheaved by frost, and hoe between the rows of these and similar crops. Make successional sowings of Peas and Broad Beans in the open quarters. These dipped in paraffin before sowing will be proof against the attacks of rats and mice.

*Forcing Department.*—Continue sowing French or Kidney Beans as fast as space permits; the most forward will require earthing up, and must be kept as near the glass as possible. Potatoes in pits or frames may be earthed up, warming the soil before using it. Where Seakale is forced on the ground a batch of crowns should be covered with pots or boxes, and surrounded and covered with about 3 feet thickness of fermenting materials. Turn over and supply new materials to fermenting beds where Asparagus roots have become exhausted, and introduce fresh roots. Pits with moveable lights are most suitable, so as to admit air freely above 50°, the temperature of the beds being from 70° to 80°. Large supplies of Mint are required in some places, which can only be maintained by the introduction of fresh roots at suitable intervals. Sow in pots or pans seed of Tomatoes, Capsicums, Basil, and Sweet Marjoram. The very early Celery will now be large enough to be pricked off in small pots singly, employing rich soil, and placing them in a warm pit as near to the glass as possible. Tomatoes, if strong enough, should be repotted as fast as is consistent with their growth. Cauliflowers and Lettuces in frames will require air on all favourable occasions.

#### FRUIT HOUSES.

*Peaches and Nectarines.*—In the house closed in November, and for

which fire heat was commenced early in December, attention must be given the trees in tying and regulating the shoots as they advance. Shoots retained on a level with or above the fruit should, unless required for extension, be stopped at the third leaf, and subsequent breaks to one joint. Remove growths not necessary for furnishing next year's bearing wood or for trees extending. Every shoot should have space for its full exposure to light and air. The fruit is swelling fast, therefore attend carefully to the borders, giving copious waterings when needed, and for weakly trees tepid liquid manure. Syringe the trees morning and afternoon, so that the foliage may be dry before night. Thin the fruits where too thickly placed, removing those at the back or under side of the trellis, retaining about one-third more than will be required for the crop. The temperature should now range from 60° to 65° at night and 70° to 75° in the day with sun heat. In the next succession house started at the beginning of January attention will be required in disbudding the trees, retaining one bud at the short base of the current year's bearing shoot, and another on a level with or above the fruit. Extensions and shoots upon them may be left 15 to 18 inches apart, which is sufficiently close for the bearing wood.

*Vines.*—Those in the house started early in December are in flower, and should be afforded a night temperature of 65°; a few degrees more when mild, and a few degrees less when the weather is severe. Artificial impregnation must be attended to, especially with Muscats and other shy-setting varieties. Commence thinning when the berries are set, and do not allow more lateral extension than can have due light and air. Afford liquid manure to the inside borders in a tepid state, and mulch with half-decayed manure. Damp available surfaces frequently. Very early Vines thinned and approaching the stoning period will require careful attention, ventilating early in the day, but allowing an advance to 80° or 85°, and close early. Afford liquid manure copiously, especially to Vines in pots, allowing a moderate extension of the laterals, particularly above the fruit. Vines started early in the year will need attention in tying down the shoots and disbudding, also stopping when the shoots have advanced so as to cover the available space with foliage that can have full exposure to light and air. The temperature should be advanced to 60° at night, 5° less on cold nights or mornings, 65° by day, advancing to 75° from sun heat, closing early, allowing a rise to 80°, with plenty of moisture in the house. Vines for affording ripe fruit in July and August should now be started. It will not be necessary to protect the outside border, but the inside should be well soaked with water or liquid manure at 85° to 90°. Damp the rods and other available surfaces two or three times a day, but allow them to become dry at least once every twenty-four hours. Maintain 50° to 55° by artificial means, and 65° with sun heat. If there is any danger of the rods breaking irregularly secure them in a horizontal position. In late houses the Grapes will ere this have been cut and bottled, but if not it must be attended to at once, pruning the Vines, dressing the cuts with styptic or patent knotting, cleansing the house, removing the inert surface soil, and applying fresh turfy loam, with about a twentieth part half-inch bones, and a similar quantity of charred refuse. Keep them as cool as possible, so as to afford a complete if only a short season of rest. Old Vines are often much improved by a dressing of lime, which may be given now at the rate of half a bushel per rod, pointing-in as deeply as the roots permit.

*Figs.*—Trees planted out and started early in the year will require attention in regulating the growth. The system usually followed is to obtain the first crop from the terminal shoots and spurs, which necessitates the removal annually at the winter pruning of nearly the whole of the shoots that have reached the limit of the trellis, also the spurs that have been stopped. This has a tendency to induce strong growth, which must be so regulated as to spread over the whole surface of the trellis, each shoot having the full benefit of the light. Keep the night temperature at 55° to 60°, and 65° by day from fire heat, commencing to ventilate a little at that temperature, allowing an advance with increased ventilation to 80°, closing the house with sun heat at 75°. Syringe the trees twice every day, and otherwise maintain a genial condition of the atmosphere. The

shoots issuing from the base of the fresh terminal growths should be stopped at the fourth or fifth leaf. The earliest-forced trees in pots must be regularly attended to with water, as neglect may cause the loss of the crop. Trees in pots started later should have the same treatment as advised for the early ones.

*Orchard House.*—The pruning of all trees that were not so treated in autumn or early winter should be attended to, cutting away any weakly growths, especially of the Peach and Nectarine, leaving the best situated and most promising growths at such distance that they will have free exposure to light and air. If the spurs are crowded it is advisable to thin them moderately, shortening any irregularity of growth to preserve the symmetry of the trees. The house should be thoroughly cleaned, and the trees when pruned be dressed with an insecticide and placed in position for the summer. Apricots and Pears should have a light position, and where there is thorough ventilation, especially when the trees are in bloom, as without this a crop of either Apricots or Pears under glass is uncertain. The Apricot when in flower should be kept dry, and there is then little danger of the blossom being injured by cold winds. Cherries should also have a light and airy position. Trees in pots when placed in their summer position should be perfectly level, and if it is desired to confine the roots to the pots each may be raised on three bricks. Borders containing trees will be found somewhat firm and dry, and if the surface be very close point it over to the depth of an inch or two with a fork before giving a thorough supply of water. Trees in pots require good supplies of water, repeated as necessary to render the soil thoroughly moist. Ventilate in accordance with the state of the weather, and when frost is not expected the ventilators may be kept open night and day.

*Melons.*—Bottom heat is essential to the successful cultivation of early Melons. Hot-water pipes are unquestionably the best, as they afford a regular and lasting heat, but very good results may be had from fermenting materials. Equal parts of stable litter and Oak or Beech leaves form a mild and durable bottom heat. They should be thrown into a heap about a fortnight before it is wished to make the bed; in a few days it will be seen whether there is sufficient moisture to insure fermentation, and if not turn it over and moisten as required. About two turnings will be necessary before making up the bed. A bed about 5 feet in height at the back and 4 feet in front will be requisite at this early season. In houses with hot-water pipes to afford bottom heat the pipes should be covered with brickbats and to about 6 inches over the pipes, and over these a layer of turves grass side downwards, and then rather heavy turfy loam with an admixture of old cowdung, about a sixth, placing in ridges or mounds a foot in depth and that width at the top, ramming it well down. Similar mounds will be required in pits or frames, and for these a bottom heat of 80° to 90° at the commencement, and for hot-water beds 80°, is suitable. Keep the young plants near the glass to insure short-jointed growth, stopping those for pits and frames at the second rough leaf, whilst those intended for trellises should not be stopped, but have the growth secured to a stick. In planting out place a little dry soot around each as a guard against slugs. A moist atmosphere will be necessary, and a temperature of 70° to 75° by day, falling about 5° at night. With sun heat allow an advance to 80° or 85°, and ventilate with great care. Sow for succession, and pot off seedlings.

*Cucumbers.*—Many of the directions concerning Melons are equally applicable to Cucumbers as regards bottom heat, but the soil need not be so heavy as for Melons. Preparations must be made for planting out young plants soon in heated pits, and seed may be sown for raising plants to be put out in frames as they become cleared of Potatoes. The weather has been harsh lately and necessitated sharp firing to maintain the proper temperature, which should not now be allowed to fall below 65° at night, 70° to 75° by day, and 80° to 85° with sun heat. Ventilation will require careful attention, closing early, damping the paths and the plants lightly at the same time. Encourage root-action by dressing the surface of the beds with fresh warm loam in a lumpy state, watering about twice a week, alternating with weak tepid liquid manure. Remove all bad leaves and exhausted growths, keep up a succession of young

fruitful growths, and stop one or two joints beyond the fruit according to the space. Afford weakly plants more extension of growth, and remove all flowers and fruit from them until in better condition. Avoid overcrowding and overcropping.

#### NOTES ON VILLA AND SUBURBAN GARDENING.

*Hotbeds.*—Prepare for making these for Cucumbers, Carrots, Potatoes, and propagating bedding and other plants. Where a single-light frame is available a hotbed should first be made, and it will then be of service for raising Cucumber plants, and also for seeds and cuttings of plants required early. Cucumber and Melon plants started in heated houses are apt to become infested with insects, which will cling to them when transferred to frames. A single-light frame prevents this, and also renders it unnecessary to make a large bed before it is wanted. Much depends upon the proper preparation of the heating material. Horse stable manure is most generally available, and this requires to be well shaken into a heap to ferment, turning it before the centre is dry, and allowing the heap to remain for another week or ten days, at which time much objectionable rankness will have passed off. If by any chance the manure should become dry it must be freely watered as it is turned. Oak, Chestnut, or Beech leaves mixed in equal quantities with the manure as the bed is being formed will moderate the heat.

Much of the manure is at first often little better than clean straw, and it is advisable to throw out the driest portion, as if used it gives off a rapid, rank, and fleeting heat. This litter may be utilised for covering the frames during the nights, and the hotbeds as the heat declines, or it may be wheeled into the cow yard and will there in a short time be converted into some of the best of heating material. Cowyard manure, although slow in effect, eventually gives a strong heat, much sweeter than that obtained from horse manure. Hotbeds at this time of year should be made about 4 feet high at the back and 3 feet high at the front. It is not advisable to tread the manure, but it should be made moderately firm with the fork.

#### QUANTITIES OF SEEDS REQUIRED FOR A SMALL GARDEN.

Doubtless the majority of the readers of this column purchase one of the advertised collections of seed, and certainly go the cheapest way to work. It does not follow that the cheapest is always the best way, and those who know how should select for themselves, cheap and good as the collections undoubtedly are. For instance, they often include very tall-growing Peas, which are valueless in innumerable cases where even short stakes are with difficulty procured. Peas may be grown with or without stakes, the former method being preferable. Suitable varieties for small gardens are William I., Dickson's First and Best, and Improved Sangster's No. 1 for the earliest crops; to succeed these—Alpha, Nelson's Vanguard, and Laxton's Supreme; these to be followed by Dr. McLean, G. F. Wilson, and James' Prolific; and for the latest sowings, Veitch's Perfection, Hairs' Dwarf Mammoth (also good for the second early crops), and Premier. The preference is given to the first name in each case, and about six pints in all may be procured. Good tall-growing Peas are Culverwell's Telegraph, Fortyfold, and Ne Plus Ultra.

Runner Beans may also be grown without stakes, and one pint of the old Scarlet will be sufficient; and of Kidney Beans half a pint each of Osborn's Forcing and Canadian Wonder, and one pint each of Early Longpod and Green Windsor Broad Beans. For the earliest supply of Beet a small packet of the Turnip-rooted may be ordered, 1 oz. of Dell's Crimson sufficing for the main crop. Carrots—1 oz. each of Early Horn and James' Intermediate, or 2 ozs. of Nantes Horn alone. Broccoli—one quarter ounce each of Purple Sprouting, Walcheren, Knight's Protecting, and Cattell's Eclipse; and small packets of Snow's Winter White, Osborn's Winter White, and Leamington. Cauliflowers—one quarter ounce Dwarf Erfurt Mammoth, and small packets of Eclipse and Veitch's Autumn Giant. White Celery—Cole's Crystal White. Red Celery—Leicester Red, a small packet of each. Cucumbers—a small packet each of Rollisson's Telegraph for frames, and Stockwood Ridge for outside. Melons—Victory of Bath, green-flesh, and Read's Hybrid, scarlet-flesh, are still two of the best for amateurs to grow. Cabbages—Quarter-ounce packets of East

Ham, Cocoa-nut and Rosette Colewort; Dwarf Green Curled Kale, Little Pixie, Early Ulm, and Drumhead Savoy, with selected Brussels Sprouts; and the same quantity of All the Year Round Cabbage Lettuce, Paris White Cos, and Black-seeded Bath Cos Lettuces, and green curled and broad-leaved Batavian Endives will suffice. Onions—1 oz. each of White Spanish, James' Keeping, and mixed Tripoli, the latter for autumn sowing. Parsley, half an ounce. Parsnips—1 oz. of the Student. Radishes—1 oz. each of Wood's Frame and mixed Turnip. Spinach—Half a pint each of Round or Summer, and Prickly or Winter. Turnips—1 oz. each of Snowball and American Red Stone, and if wanted very early a packet of Early Purple-top Munich. Tomatoes—a small packet of either Earley's Defiance or Hathaway's Excelsior, and Vick's Criterion or Conqueror for pots. Vegetable Marrow—small packet of the Long White. Of early Potatoes, which are most profitable, two pecks of either Mona's Pride or Rivers' Ashleaf, and one peck each of Snowflake and Schoolmaster. Mushroom spawn half a bushel, or more if several beds are to be formed.

#### SELECTION OF FLOWER SEEDS.

Of plants that may be raised from seed and grown in pots for the decoration of greenhouses and conservatories the following may be ordered:—Balsams, Tuberous-rooted Begonias, Browallia elata, Cineraria, Primula sinensis, Cyclamen persicum, Calceolaria, Gloxinias, Schizanthuses, Petunias, Pyramidal Mignonette, Cobæa scandens, Lophospermum scandens, Torenia Fournierii, Cockscombs, Coleus, Abutilons, Solanum capsicastrum, and Capsicum Princess of Wales. Of fine-foliage, subtropical, and bedding plants, the following are easily grown from seed:—Acacia lophantha, Amaranthus Henderii, Solanum marginatum, S. Warscewiczii, and S. robustum, Eucalytus globulus, Chamæpeuce diacantha, Cineraria maritima, Amaranthus melancholicus ruber, Cannas, Zea japonica, Ricinus Gibsonii, R. communis major, R. sanguineus, Perilla nankinensis, and Nicotiana grandiflora. For the flower garden the following are suitable:—Antirrhinums, Ageratums, Asters (the Victoria are very good), Calliopsis, Clarkias, Candytuft, Convolvulus major and minor, Delphinium formosum, Dianthus, Eschscholtzia crocea flore pleno, E. mandarin, Godetias, including Lady Albemarle, Hibiscuses, Lupins, Larkspurs, Linums, French and African Marigolds, Mignonette, dwarf Tropæolums, Pyrethrum Golden Feather, Poppies, Portulaccas, Tropeolums, Sweet Peas, Scabious, Stocks, Wallflowers, Sweet Williams, and Virginian Stocks. To all of the foregoing allusion will be made when the proper time arrives for sowing.

## THE BEE-KEEPER.

### EXAMINING STOCKS.

WHERE bees have been wintered in hives without division boards, so that they have had a large space to keep warm, it must be that the low temperature of the past month has very much reduced their stores. The small quantity of food bees consume if properly wintered is so remarkable that those who have kept themselves abreast of the times need have no fear but for others. It is highly important that if the temperature does not admit of a thorough examination, so that the condition of things may be certainly ascertained, barleysugar should be given at once under the quilt or between the combs of skeps, unless, indeed, the bee-keeper has evidence that such help is not needful. The question of wintering we seem now to have fairly mastered, and my results are so extremely good after the testing of the late frost, that I hope to give a full account of them in a week or two.—F. CHESHIRE.

### WOODEN v. STRAW HIVES.

NOW there is so much discussion about wooden and straw hives I wish to say a few words. I began bee-keeping with straw hives; the bees succeeded well, and I soon learned to do anything I wished with them without fear. I visited the bees very often, fed them, and kept them warm. On receiving the Journal every Thursday the bee department had my first attention; I obtained much pleasure and profit from its pages, especially

from Mr. Pettigrew's contributions. I read about wooden hives and their furniture, but I had never seen one. At length a kind bee-keeper invited me to see his apiary. There I saw the bar-frame hives, and the way they were employed was fully explained to me. The apiary comprised Stewartons, east Stewartons, and Woodburys, with Neighbour's and Pettigrew's straw skeps. The wooden hive pleased me so much that I obtained one, a Woodbury, well made with double walls; it was filled with foundation combs, and received a splendid lot of bees, which thrived well on the Limes and filled the bars in thirteen days. The season was then over with us. My next care was to make it strong for winter, so I drove the bees from two skeps and united them to it. As it was my intention to do away with the skep I made preparations in good time. Spring soon arrived, the wooden hive was placed on a clean board and the bees were fed until May. I invited a friend to see my bees; we opened the bar-frame which was good, but a skep by its side, 14 inches wide and 8 inches deep, was crammed full of bees ready to swarm the first week in May, while my Woodbury would be three weeks or a month later. The bees in it were less in numbers, ate much more food, did not gather so much honey, and the hive was very wet inside, while the straw hive was very dry. Both had young queens; the Woodbury queen was the finest I ever saw, but the straw skep was the best, and I advise cottagers to keep to it.

I desire to give a few remarks upon foundation combs. It is the greatest advantage the wooden hive has over the straw skep. My experience tells me it is unnecessary; give a skep as much sugar syrup to start it as you would foundation comb, let the expense be equal, and judge by the results. I confess I had straight combs in the bar-frame, which cannot always be obtained in the skep; but as to the manipulation, I would as soon have one as the other. I use the foundation in the sectional supers to have the comb straight and give a start. I run them in with a teaspoon; with a little practice it is better than the smelter, quite as clean, cheaper, and quicker. I never set large pieces in the supers as Mr. Pettigrew did. I was sorry to see such a weak point in his otherwise excellent practice. If he runs them in properly he will find it a great advantage. I have come to the conclusion that I shall use Pettigrew's straw hive and work sectional supers on the top. Cottagers that have not seen his book have yet the best practical book on bees to read. I have a friend who this year has from 40 to 50 lbs. of super honey in his Pettigrew hives besides one good swarm from them far superior to any of his wooden hives, which did not swarm all the season. This is the first time I have written about bees, but it may not be the last if the Editor thinks this letter worth a place in the Journal.—A LOVER OF BEES.

### CRUDE AND PERFECT HONEY.

IN the review of the "Handy Book of Bees" the soundness of the author's views or opinions on crude honey is questioned. Nay, the reviewer ventures to call them "a fad," and suggests their omission in a future edition, and wisely says that opinions will never be admitted as facts till they have been demonstrated to be so by irrefragable evidence. Well, what evidence would the reviewer like? What would he consider irrefragable? If my evidence and that of many other bee-keepers is worth anything, what the reviewer calls "prejudice" and "opinion" is something better and more satisfactory—viz., facts that cannot be gainsaid, as they have been "proven" again and again, and may be proven in five minutes in any apiary while bees are gathering honey. In this matter I have made no discovery. That bees collect crude honey from flowers and convert it into perfect honey in their hives was well known before I was born. Before I was many years old I became acquainted with this fact, just as I became acquainted with the fact that working bees are less in size than drones. Since that time I have seen, tasted, and handled both crude and perfect honey a thousand times. The difference in taste and appearance of crude and perfect honey is so different and distinct that I am astonished the reviewer has not seen the difference. Evidently my statement goes for nothing with him. Ocular demonstration, and probably nothing else, will convince him that perfect honey is manufactured by bees from the sweet syrup of flowers gathered by them. Very well. Let me suggest that at the close of a day of honey-gathering a bar of brood comb be removed from the centre of a hive and examined. The empty cells amongst the brood cells will be found half full of glittering honey. This is crude honey, and may be easily shaken into a plate or dish and tasted. Another comb may be taken out and examined and be found like the first with many cells half full of crude honey, but let the second comb be returned with the honey unextracted. If the combs be examined on the morning following it will be found that the crude honey has been removed from the centre of the hive to the extreme outside or ends of the combs. If your reviewer were to see these things he would surely ask himself this question—Why do the bees put the honey amongst the brood at first? And why not carry it to the store combs at once? If the

syrup or sweet juice of flowers remain as it is gathered, we may well ask these questions, and come to the conclusion that bees have yet to learn the economy of labour.

Let us take another consideration. If the gentleman who reviewed the "Handy Book of Bees" has had experience in supping, and has been observant in this work, he must have seen that the honey and combs in supers increase as fast at night when bees are at home as they do in the day when they are gathering honey in the fields. This being an unquestionable fact, it may be asked where the honey stored at night comes from. Intelligent reasoning, supported by the evidence of three senses—viz., seeing, tasting, and handling, supply the answer.

I have taken as much as 15 lbs. of crude honey from a hive and jarred it up, and thus kept it for a considerable space of time. It never became honey in the jars. It was ultimately given to a hive on which was a super partly filled. The bees of this hive took it rapidly and converted it into honey proper. The reader will naturally ask why so much crude honey was allowed to accumulate in this hive. The explanation is easy. The hive was a strong one, without brood at the time, and therefore had plenty of empty cells and field hands. A glut of honey came, and so much of it was gathered by the bees during sunshine that they were unable to convert it all into real honey at nights (and this is not an uncommon occurrence during times of great gatherings of honey). The bees were driven from this hive on the evening of the fourth day of the honey glut. If they had been permitted to remain in their hive for some time longer, or if bad weather had kept them from outdoor work for a day or two, the 15 lbs. of flower syrup would have been reswallowed and disgorged and thus made into honey proper. If your reviewer would feed two hungry bees with good honey, and catch other two returning from the fields loaded with crude honey, and dissect the four bees if his tenderness of heart would allow him to do so, and examine their contents, he would be converted on the spot to the views I have enunciated. Though I have no interest in the sale of the book which has been named and revised, and which belongs wholly to the publishers, I cordially thank the reviewer for his friendly and favourable notice of it.—A. PETTIGREW.

#### TRADE CATALOGUES RECEIVED.

H. Cannell & Sons, Swanley, Kent.—*Illustrated Floral Guide for 1881.*

James Yates, Stockport.—*Catalogue of Flower and Vegetable Seeds for 1881.*

W. W. Johnson & Son, 5, Bridge Street, Boston, Lincolnshire.—*Catalogue of Vegetable and Flower Seeds.*

Wm. Hugh Gower, Tooting, London.—*Catalogue of Flower and Vegetable Seeds (Illustrated).*

**Pruning Hollies** (*J. J., Cork*).—You may slightly prune the shrubs now, doing the work with a sharp knife, severing the growths close to the leaves remaining on each shoot that is shortened. September is also a good time for pruning the shrubs.

**Cutting Down Roses** (*Idem*).—If you have only "2 or 3 inches" of stem destitute of foliage they will not be unsightly during the summer, and to plant more than 2 or 3 inches deeper than at present would probably injure the Roses considerably. Cannot you cut some of them down? Fresh growths will be produced freely from the old wood if the plants are healthy, but may not flower so freely the first season. In cutting down, however, you must be careful not to prune below the "worked" part, or you may have a cluster of Manetti growths.

**Hyacinths Defective** (*James Carter & Co.*).—We have carefully examined the plants, and never dissected firmer, sounder, and more healthy bulbs. We consider the defects of the plants wholly due to some error in culture. Were the bulbs potted early enough? Have the plants been supplied with over-strong stimulants? Have they been placed in a warm house before the pots were filled with roots? We have probably indicated the cause of the failure, and think the plants have been overfed and overforced.

**Grafting Oranges** (*W. M., Doncaster*).—The following extract from Mr. F. W. Burbidge's work on the propagation of plants so well expresses what you require that we need add nothing to it:—"Like all other cultivated fruits Oranges are extremely variable in earliness, size, colour, and flavour, this being partly owing to their being propagated from seed, and partly owing to the sudden development of sports or bud-variation. Good varieties are readily propagated by grafting on the Lemon stock or on seedlings of the common kinds. Seedling Lemons are found to be more vigorous, to grow faster, and to make better stocks than Oranges. Seeds taken from imported fruit grow freely if sown in moist earth and placed in a greenhouse or vinery, and these may be splice, whip, or side grafted in a close case in heat at almost any time, preference being given to the early months of the year when vegetation is most active."

**Planting Seakale** (*J. Sands*).—The roots may be planted in rich deeply trenched ground immediately the weather and soil are favourable for the work being cleanly performed. The rows may be 18 inches apart, and the sets a foot

asunder in the rows. The terminal crowns should be removed, and growths will issue from dormant buds at the base. If the crowns are left they will only produce flowers, which exhaust the plants and retard the growth of the basal buds that must be depended upon for producing crowns to afford produce next year. The tops of the sets should be just beneath the surface of the soil.

**Early Prolific and Early Crimson Pine Strawberries** (*J. E., Aberystwith*).—They are not synonymous, as the annexed woodcuts and descriptions clearly show. *Early Prolific*.—Fruit large, and large medium. The woodcut depicts a fair medium size. In some soils it is decidedly larger. Colour bright glossy vermilion, becoming a little darker when very ripe; seeds slightly embedded; flesh white, firm, and juicy, with a delicious refreshing flavour peculiar to this variety alone. It is decidedly early. *Early Crimson Pine*.—Fruit handsome bright crimson colour; seeds rather prominent; flesh dullish white and sometimes pink, very juicy, with a rich piquant Pine flavour. The fruit is much like British Queen, observes similar shapes as it ripens, and has an equally rich Pine flavour, but colours up better all over the fruit. It has the advantage also of coming in some three weeks before that excellent variety. Figures and descriptions of other varieties of Dr. Roden's Strawberries will be found in our issues of September the 9th and 16th, 1875.

Fig. 29.—Early Prolific.

**Removing Asparagus** (*Rus in Urbe*).—We doubt if it would be profitable to remove the Asparagus as you propose, as plants ten years of age can seldom be transplanted well, and never if they are removed before growth commences, when the work needs to be done with extreme care, as if the growths an inch or so long are broken in transit or the roots dried by exposure success cannot be expected. Two-year-old plants are the best for removal and transplanting. Much labour is involved in taking up old plants to preserve their roots intact, and then even when great care is taken in transplanting—such as preserving the roots moist, and spreading them out their full length in the new position, working light soil amongst them, covering 4 inches deep, and watering them as needed—a great number often fail to grow, and the remainder do not become quickly established.

**Cauliflowers for Succession** (*Dorking*).—You may maintain a supply by sowing at intervals as recommended on page 118 last week, Early Dwarf Mammoth and Walcheren, with two additional sowings of Veitch's Autumn

Fig. 30.—Early Crimson Pine.

Giant in March and April. These, with good soil, culture, and shelter as needed, will produce heads from the end of May till January, and from January to May you may have Broccoli, the seed being sown from March till June.

**Cabbage Plants Clubbing** (*An Amateur*).—The clubbing to which you refer is known as ambury, a disease peculiar to the Cabbageworts, and is most common in light sandy soil. Cabbage plants are frequently infected with ambury in the seed bed, which infection appears in the form of a gall or wart on the stem near the roots. This wart contains a small white maggot, the larva of a little insect called the weevil. If on the gall and its tenant being removed the plant is again placed in the earth where it is to remain, unless it is again attacked the wound usually heals and the growth is little retarded; on the other hand, if the gall is left undisturbed, the maggot continues to feed upon the alburnum or young woody part of the stem until the period arrives for its passing into the other insect form, previously to which it gnaws its way out through the exterior bark. The disease is now almost beyond the power of remedies. Your soil would be much benefited by a heavy dressing of lime and salt; the former at the rate of eighty bushels per acre, the latter at the rate of 5 or 6 cwt., the whole being dug in as soon as weather permits and well mixed with the soil. The ambury may usually be avoided by frequent transplantings, for this enables the workman to remove the excrescences upon their first appearance, and renders the plants altogether more robust and ligneous, the plant in

its tender sappy stage of growth being most open to the insect's attacks. As a further precaution, the plants before being placed in the ground should be dipped up to the leaves in a puddle formed of half soot and half garden soil, which adheres to the stems and roots and renders them distasteful to the insects.

**Peach Tree Buds Dropping** (W. F. Reigate).—The system of forcing you appear to have adopted is a very satisfactory one, and should not be the cause of the buds falling from your tree. There are many minute causes which will result in Peach trees throwing off a number of their buds, which can scarcely be determined without a thorough knowledge of the treatment of the trees after they shed their foliage, and the condition of the roots and growth. Dryness at the roots during the resting period will cause the buds to fall soon after starting, and many failures result from this cause alone. Again, if the trees have been suddenly changed from the treatment they would receive while resting to that of closing the house to maintain a given temperature with insufficient air, that is sufficient to cause the buds to fall from some varieties, while others would not be affected by such a sudden change. The Royal George is much better adapted for early forcing than the Noblesse, and is not so likely to cast off its buds if kept a little too close as would be the case with the latter variety. In forcing the Noblesse in an early house more air should play about the tree from first starting, or the buds are almost sure to fall as soon as there is the slightest move perceptible. It is not really suitable for a very early house, and does much better in a cooler position. When forced early it must be very carefully and gradually brought forward with abundance of air night and day if success is to be looked for. If the wood has been crowded in the trees, or left too thickly so that sun and air could not penetrate to thoroughly ripen it, the buds are always liable to fall when the trees have been started early. The flow pipe being pressed into the bark of your tree is certainly prejudicial to its well-being, and may be the cause of the buds falling. If the tree has been planted the number of years you say, and has never been lifted or disturbed, the roots may have penetrated into bad soil, or if the border has become sour in any way the buds are almost sure to fall. It would be well to carefully lift the tree after its growth is made, and some time before the foliage falls, bringing the roots nearer the surface, and adding some fresh soil about them. It should be kept well syringed and shaded for a time after lifting to keep the foliage fresh until fresh roots are formed. It would not be wise under the circumstances to lift it now. Heavy cropping for a number of years is a sure cause of failure and proves in the long run a gigantic evil, and judging from the number of fruits you say has been taken from the tree is sufficient alone to cause the failure. What appears to be light cropping for a few years in the end often proves too heavy, and exhausts the energies of the trees until they force upon cultivators a season of rest—"free from the strain of fruit-bearing"—so as to recruit themselves.

**Vines for Planting** (A Reader, Apr).—Shorten the canes at once as you propose, and dress the wounds with styptic or painter's knotting to prevent bleeding. Keep them in a cool house so that they may start into growth gradually, and when the growths have fairly started, say half an inch long, turn the Vines out of the pots, removing all the soil from the roots, lay them out quite straight in the border, cover them 4 inches deep with soil, give them water at a temperature of 100°, and then mulch the surface of the border with manure. The soil in which they are planted should be fresh turfy loam, and if a fourth of wood ashes or charred refuse can be mixed with it, it will be an advantage. The stems of the Vines should not be buried much if any deeper than they are now in the pots.

**Names of Plants** (S. B.).—1, *Phaius grandifolius*; 2, *Seneio macroglossa*; 3, *Fittonia Pearcei*. (Inquirer).—The specimen with rose-coloured flowers is *Centropogon Lucyanus*; the other appears to be a garden variety of *Helleborus atrorubens*. (Amateur).—1, *Pteris eretica albo-lineata*; 2, insufficient, but probably *Pteris arguta*; 3, apparently a small specimen of *Phlebodium aureum*.

**Stewarton Hive Management** (J. K.).—You would increase breeding space by putting your second box (body box) under the full one, at the same time closing its door and allowing the bees to enter through the lower box only. The slides will all be withdrawn from the lower box, but short stops—i.e., small pieces of slide, will be inserted to prevent the escape of bees. Whenever it may be necessary to separate the boxes or remove supers a thin wire must first be passed between them to cut all comb attachments. Bees build comb to the bottom of sections when they can pass freely under them, but not in any other case, and this is a rule of universal application, therefore the body boxes would be united as you suspect. A book by the Rev. E. Bartrum on the management of the Stewarton is now in the press and will be shortly issued by Longman and Co.—F. C.

#### POULTRY AND PIGEON CHRONICLE.

#### THE COMPARATIVE ADVANTAGES OF FATTENING BULLOCKS AND SHEEP.

It has always appeared to us that farmers in general have held ideas upon this matter which were vague, and frequently not founded on calculation, so as to enable them to form a just estimate of the advantages of keeping sheep for fattening purposes in preference to bullocks, and *vice versa*. A friend once told us that since we had a discussion upon the subject he had seen many farmers, and had been surprised at the apparent difficulty most of them experienced in answering the question addressed to them in reference to it, and likewise at the wide range of the replies. The question was, "How many sheep do you consider equal in consuming powers to a bullock?" Some replied five, and other ten—a very wide difference to exist among practical men. We therefore undertake the task of giving the home farmer a series of calculations, which, although the subject is extremely intricate and complicated, we have based not only upon our own experience, but they are supported also by the able assistance of many practical agriculturists, and in consequence may be accepted as a close approximation to the truth. As evidences of the complicated and difficult task we have undertaken we propose only on the present occasion to draw comparisons between bullocks and fattening sheep during the winter months, and upon such food as usually forms the diet of these animals on the arable farms of different districts of the kingdom. The cost and feeding of bullocks and sheep of various ages and at different periods of the year would, indeed, be a large subject, and it is from that circumstance we desire to limit our observations and calculations on this occasion to the comparative advantages of fattening bullocks and sheep on arable farms only, chiefly because we intend on a future opportunity to take up the same subject, referring only to fattening on the grass and pasture farms. In order to carry out our intentions we shall confine our comparisons and calculations to the feeding of cattle and sheep in the winter months, because root-feeding at this period of the year is the basis of fattening for both these kinds of stock. We purpose limiting the period of fattening by taking the period of twenty weeks, say from the middle of October to the middle of March, so that the best time for winter feeding may be chosen for the purpose.

In commencing we introduce a few remarks upon ascertaining, if possible, the particular stock best adapted to arable farms in general, and which yield the most profit in consuming roots and other crops for the purpose of manuring the land. No doubt some farmers will consider that the keeping of stock seldom yields a profit in itself, and will view it chiefly as an agricultural operation, whereby we may dispose of certain vegetable products of the farm, which frequently cannot be sold in any other way than by the production of live stock, and also as a means whereby we may be enabled to manure our arable land. As the basis of our arguments relating to this interesting and important subject we will proceed to give a statement of our estimates of cost of feeding and the food consumed by both oxen and sheep in the manner which they are treated upon arable farms in general—namely, the oxen under cover and the sheep in the open field, and by taking it in this way it is no proposal of ours, or whether it is fair or unfair. It is sufficient for the practical statement which

we shall make that it is a custom of the management of stock on arable farms which has previously existed, and is still prevailing.

£0 5 7

We must now—in order that our debtor and creditor account, which involves somewhat intricate and complicated calculations, may be the better understood by the home farmer—give some practical explanations relating to the items in these estimates. Let us take first the selection of bullocks of either the Devon, Hereford, or Shorthorn breed at about three years old, and if purchased in October, when they are being sold off the grass land and pasture farms, of a condition just beneath the butcher's requirements, and to cost on the average of seasons £17 each when they enter the boxes, and selling out at £27 each. Taking secondly the sheep two-teeth wethers or tegs, of either Hampshire Downs, South Downs, or Cotswolds in good condition, to cost on the average of seasons 45s. each when they enter the field, and selling out at 65s. each. The foregoing account will require probably some explanations as to how the items are made out. Referring to the value of a ton of roots for consumption by bullocks we will suppose a field sown half with Mangolds and half with Swedes, the former producing 24 tons per acre, the latter 16 tons per acre; average crop 20 tons. The cost of this crop—including tillages, manure, rent, rates, tithes, &c.—we will estimate at £6 10s. per acre; thus the roots will cost 6s. 6d. per ton; pulling, storing, and preparing the Mangold, 25s. per acre; ditto the Swedes, 15s. per acre; average cost of preparing, &c., 20s. per acre, or 1s. per ton. But here we must observe that the comparison between the roots for bullock consumption and that for sheep must cease, and to proceed we will estimate the cost of carting the roots to the homestead, perhaps a quarter of mile distance, for on the outlying light or poor land the roots would be fed with sheep only. Carting home and storing Mangold at per acre, 35s.; carting home, &c., the Swedes, 25s. per acre; average cost of carting home and storing, 30s. per acre, or 1s. 6d. per ton. Charging the fodder, oat straw, at market value in the place at 30s. per ton is fair, because the straw may be sold off, the equivalent value being returned in purchased manures, which may raise the question as to the policy of selling or consuming by cattle. The litter straw we have only charged at 10s. per ton, because straw, which could not be sold, of an inferior description, will answer every purpose in the boxes. We estimate the carting and spreading dung returned to the land (a bullock making a ton of dung per month) at 3s. per head per week. We reckon interest on £8 for twenty weeks at ten per cent., being the amount of extra capital employed in the purchase of an ox over that of the four sheep, the former costing £17, the latter £9. The attendance is estimated at 8d. per bullock per week; one man to feed, litter, and attend to twenty-five bullocks. This item closes the bullock account on the debtor side.

On the credit side we have estimated the increased value at 10s. per week, for we have found in our business for a number of years that bullocks of various ages have on the average increased in value 10s. per week during the twenty weeks' feeding

on roots, &c., in the winter months. We have reckoned the value of the manure at 5s. 4d. per ton, and allowing each bullock to make a ton per month, this gives 1s. 4d. per week, and this we believe to be very near the truth; but whether it is, in fact, more or less, it does not affect our comparative calculations, because we have charged the same value of manure in the sheep account. As regards the sheep stock account, debtor side, the value of the root crop for consuming in the open field will be the same as for bullocks up to the point where they are pulled, prepared, and stored, which will give the value of 7s. 6d. per ton. We have charged the sheep with hay, because practically we cannot make fattening sheep eat straw without cutting it into chaff and mixing with superior food, which will lead into expense and waste. We have charged the hay at market price in the place, which is about the sum it costs to grow and secure it, and may therefore be considered a fair charge. On the credit side of the account we have reckoned the manure of the four sheep at the same as the ox, but it should be remembered that some of the manure is lost by exposure and heavy rains. We have calculated the sheep, whether two-teeth or tegs, to gain 1s. per week for twenty weeks' feeding, in accordance with the average result for a number of years on our own farm, as well as many others, and as a rule it will be found over the mark rather than under.

(To be continued.)

WORK ON THE HOME FARM.

*Horse Labour.*—This has been continued upon some hill farms and dry loamy vale land by fallow ploughing in those cases where uncompleted before the great snowstorm of January 18th, which by farmers will be remembered for a long time as the disastrous snowstorm of 1881. Ploughing and pressing should now be done of the Clover and Saintfoin leas for Oats, Peas, or Vetches. We, however, like drege best, for when Barley is mixed with the Oats the crop not only yields a better and heavier sample of grain but the plant is more likely to come with greater regularity, for upon lea ground the wireworms are frequently found to destroy some of the young plants; but we have noticed that they will very seldom eat off both Barley and Oat plants, as the Barley being of quicker growth often grows out of the way, whilst the Oats fall a prey to the wireworm to some extent. Upon the strong loams the first opportunity should be seized to sow the Beans, and either late Peas or winter Vetches may be mixed with them; for this plan not only diminishes the risk of blight, but after the second horse-hoeing the Peas or Vetches spread over the space between the rows of Beans, and keep down the growth of various weeds by shading the land.

*Hand Labour.*—Guano and any artificial manure which requires manipulating and preparing beforehand for use may now be broken down and passed through a quarter-inch wire riddle in readiness for use at the appointed time; this can be done in wet weather in the manure house under cover, so that neither men or women may lose time and pay during weather unfitted for outdoor labour. In preparing guano and such manure after being passed through the sieve it may be bagged up again, so as to be available when the period for its application arrives either for the Potato or Mangold crops, as well as for Lent corn or upon any land to be planted with Cabbages. Men may now be employed in preparing seed beds for the growth of such vegetables as Cabbages, Kohl Rabi, Broccoli, &c.; and if the plants are not grown under the care and superintendence of the gardener at the mansion it is best to prepare a bed or beds for the growth of seeds in some corner of a field or headland, in which the plants are to be set out. This will save time and labour at planting, and also allow of the plants being set as fast as they are pulled, and in some seasons this is very important. As soon as the land can be worked freely it should have a dressing of guano forked in, and the seed sown when the land is dry enough. The seed may, to facilitate the hoeing and pulling of the plants, be drilled with a hand garden drill at about 14 inches apart. Upon the fields or pieces of land where Cabbage plants were set in the autumn we fear that many plants have been destroyed by wood pigeons, larks, and rabbits if planted on the flat or level ground; for the late snow and frost will show the advantage of planting between the furrows of the land under stretch, for they will not only have felt the effect of frost less severely, but where covered with snow they will have been kept free from the attacks of enemies, as well as protected from the cutting winds which accompanied the snow.

The Wheat plant we find has been injured on the open districts where the land was left bare by the snow drifting before the wind. It is, however, too early to say whether damage of this kind will be fatal to the plant as a whole, for if one or two plants only are left in a square foot of ground, tillering upon good land may maintain a plant sufficient for the production of an average crop. We also understand that in some cases both Turnips and Swedes have been destroyed by the frost. Should this prove to be the case to any great extent it will be a very serious matter as regards the provision for stock in the spring, which shows that wherever the land and climate is adapted for the growth of Mangold that they should be grown to a much greater extent than heretofore; because after being securely stored they are the sheet anchor of stock farmers, and the

only safe provision for stock. The home farmer should call to mind how often we have advised the heaping and covering, commonly called pitting, of the Swede crop, not only to protect the roots against frost and rabbits, but also to prevent them from striking winter roots and throwing up early greens, which they will do during a mild winter, and very much injuring their quality or feeding value for stock. It has been our own system for many years to pit the whole of our roots, whether Swedes, Mangold, or Carrots, in the field when required by the sheep to be fed on the land, and this plan also facilitates the daily use of the roots, for whether frost or snow prevails one heap at a time is opened and passes with little trouble or waste through the Gardner's cutter. About four or six rods' produce—according to crop—furnishes roots enough for each conical round heap to be handy at making up and also at the opening for use, so that one or two heaps, according to the size of the flock, may be used daily enclosed by the fresh fold. As we have lately called the attention of the home farmer to the plans we advise for the feeding both ewes and lambs we need not repeat it here, but with such weather as has prevailed all the minutiae of the management we described will have been required to maintain the condition of the animals.

With respect to the stock in the yards and cattle courts the roots in store will have been handy and useful in furnishing both heifers or steers, as well as dairy cows in calf, with a generous supply during the late bad weather, and no doubt they will have passed through the winter thus far with satisfaction if a full supply of sweet straw or ordinary hay has been given. The fattening pigs which have received pulped Mangold or Carrots mixed with barleymeal, mixed in the proportion of one-third meal at first, gradually reducing until the last fortnight of feeding, when the roots may be omitted and meal only given to finish off the animals for the butcher. The breeding sows which are in farrow should have a small yard and hovel to run in, and be fed with roots in part, either Swedes or Carrots, and wash with a little meal in it twice a day; but we always like to contrive the sow's yard to be fenced with moveable iron hurdles and placed near the cart-horse stables, so that the long straw manure thrown out every day should furnish a bottom and bedding for the sows to eat their roots on, and in order also that the manure may not only be trodden down and preserved but further improved by the droppings of the pigs.

#### VARIETIES.

**THE BRIGHTON POULTRY SHOW.**—We regret to learn that the Committee of this excellently conducted Show are £130 out of pocket. The Secretary, Mr. T. K. Cucksey, Chichester, Sussex, appeals to successful exhibitors for subscriptions, and announces that, notwithstanding the monetary failure of the last Show, it is intended to hold another in October next. The Committee have kept all their promises to exhibitors in a most exemplary manner, and have, notwithstanding the loss, sent out the ornamental prize cards which they promised. We trust they will receive support from fanciers.

— **"PRACTICAL ARTIFICIAL INCUBATION,"** by Edward Brown (Cassell, Petter, Galpin & Co.).—We have received the second edition of this work, which we reviewed at length when it was first published. The new edition is based very much upon the lines of the former one, but Mr. Brown has added details of all the recent inventions and improvements both in incubators and rearing apparatus. It is the most complete work upon the subject yet published, and will well repay a careful perusal.

— **WOODSIDE, ABERDEEN, POULTRY SHOW.**—A correspondent obligingly sent us last week a report of this Show, but it arrived too late for insertion. It was the tenth annual Exhibition. Considering the very stormy weather that prevailed the display was a very creditable one. The entries, including poultry and Pigeons, amounted to about 400. Messrs. Campbell and Stewart judged the poultry.

— **THE COLORADO BEETLE.**—The Devonshire people have, we learn, been in a considerable state of excitement by reason of the arrival of this beetle. It appears that a Mr. Horton brought with him from Canada in December a number of these insects. Some witnesses say there were nearly thirty, and the introducer himself admits he had twenty. He says that he looked upon the beetles as a curiosity, and wished to show them to his friends. However that may be, most of them reached this country alive. Mr. Horton has been charged before the magistrates and fined £5, a penalty which has been indignantly condemned by the Devonians as altogether inadequate to the offence. Diligent search has been made for the insects, and it is believed they have all been destroyed. In 1874 a correspondent stated in our columns his opinion, "that if the pest were introduced into England it would be by some enthusiastic naturalist, who would get some

precious specimens over alive, and then expect a medal from the Entomological Society for his skill and perseverance." It will be seen now that a different "reward" awaits those who succeed in bringing over the dreaded beetle, and they richly deserve it.

— **FOOT-AND-MOUTH DISEASE.**—The order which prevents the holding of markets for store stock all over the country, or nearly so, and only permits sales of fat stock under severe restrictions, including slaughter within six days after exposure for sale, will cease to operate on March 1st next. It may be presumed that the extension of the provisions of the order for a longer period—say to the end of March—will be a matter of consideration with the Privy Council; and we may, without expressing our own opinion, suggest to stock-owners and others concerned that the views which the Privy Council may entertain may, in some degree at least, be influenced by the opinions of practical men. No time, therefore, should be lost in bringing these opinions under the notice of the Government. Chambers of agriculture and farmers' clubs might claim to speak with authority on the subject. On Monday evening in the House of Commons Mr. Marjoribanks asked the Vice-President of the Council whether, in view of the rapid spread of foot-and-mouth disease, he would consider the advisability of the total prohibition of the entry of all live stock from England and Scotland until May 1st next. Mr. Mundella said then, finding the disease was extending northwards and had reached Durham, an order has been passed which came into force on January 28th, by which any local authority in Scotland can prohibit the entry into their district of animals from any part of Great Britain. We received on Saturday last an official communication from the Town Clerk of Glasgow to the effect that the local authorities for that city have prohibited the entry of any animal from England or Wales between February 3rd and April 1st.—(*Agricultural Gazette*.)

— **AGRICULTURAL PROSPECTS.**—Prospects on clay lands have been drowned, both literally and figuratively, during the past week. In many districts, especially in the unlucky midlands, there was no prospect but water; the direction of the roadway and extent of the fields being marked out by trees and high hedgerows, whilst the course of the rivers was indicated by the bridges only. Where arable lands have been flooded again and again—in Nottinghamshire there have been seven distinct and extensive floods—it is impossible to form any idea of what farmers' reasonable prospects may be, but on clay lands generally it is useless to shut our eyes to the fact that prospects are very materially worse than they were a week ago. When the frost broke up the land was not in bad form for the time of year; but it is in very bad form now. It is impossible to say what may happen in the way of weather, but unless it should prove altogether favourable there is at present very little prospect of making good seed beds in March. Some of our correspondents speak of work being in arrears, and that has now become a very serious matter. Root crops outstanding at the time of the great storm and frost are now nearly worthless. As a matter of fact, the stock of roots in most cases now consists only of such as have been stacked. Where the young Wheats were exposed they now appear to have been hit very hard, but they will pull through, no doubt. Altogether, there has been, in our opinion, a very sharp fall in the prospects barometer during the past week.—(*Mark Lane Express*.)

### POULTRY AND PIGEONS

#### SPRING POULTRY NOTES.

EVERY season in the poultry yard has its especial cares, on the due observance of which success later on much depends. It may not be out of place to enumerate a few points to be thought of in the present month.

Young chickens should not be allowed to run out into frosted ground, least of all on to grass covered with hoar frost. Their feet become contracted, the twist in the toes grows with their growth, and often at the Crystal Palace or Birmingham we hear it said, "What a grand cockerel! he would have been first but for his twisted toes."

Ducks should now begin to lay regularly after the break-up of

the frost. It is a common thing to find several eggs one morning, and then no more for some days. This is almost a certain sign that they are dropped in the water. Ducks almost invariably lay early in the morning, so they should be shut into houses overnight and kept in till they are likely to have laid their eggs in the morning.

Turkeys also want watching as the laying season comes on. They wander about in search of a nest, often to immense distances, and far beyond their owner's domain. They may before they have laid be easily induced to take to a desirable nest, but when once one egg has been deposited in a place they are very pertinacious in returning to it, quite regardless of there never being a single egg left in it. We have in this way often had Turkey eggs stolen by people who had discovered the foolish hens' favourite laying place.—C.

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 84.)

#### FORMING A STRAIN.

HAVING arrived at the practical conclusion that in-breeding, though it may be sometimes productive of evil results, is a necessity, we now come to the consideration of the best method of establishing a strain. Every true fancier has for his object the attaining of perfection in the particular breed or variety which is the subject of his choice. He sets before himself an ideal which he desires if possible to attain, and the more difficult it is to attain that ideal the more exciting and interesting is the pursuit of it. The beginner, therefore, should, before attempting to breed or exhibit any variety, have fixed and clearly settled in his mind the standard points of the variety. These are, for the most part, well settled, and can be ascertained by a perusal of the various works upon the subject, and by a careful study of the winning birds at some leading shows.

It may seem at first sight to the outsider that the breeding of poultry or Pigeons is a mere child's play, unworthy of serious attention, but a practical acquaintance with the subject soon teaches the fancier that the attainment of absolute perfection in any variety is almost an impossibility. There are as a general rule so many points, all of which require to be bred for, that it is an extremely difficult matter to unite them all in perfection in one individual. It is for this reason that even the most successful exhibition birds are open to hostile criticism, and the different degree of weight attached by different judges to failure in the various points of a breed is the most fertile source of those variations in judging which so frequently puzzle a beginner. We will suppose, then, that the reader has determined which breed or variety he means to keep, and has obtained a fair knowledge of its leading points. Having reached this point there are the proverbial three courses at least open to him, and which of the three he chooses must depend upon his individual taste and circumstances. The first, and in one way the most simple course, and that which is most likely at once to produce a profitable return, is to go to a breeder and exhibitor of high standing and select from his yards a breeding pen of birds of the same strain. This, however, can hardly be called forming a strain; it is rather taking up the results of another man's labours and forming a sub-strain for the merit of which as a strain he is entitled to all the credit. There are these further objections to this course, that if the exhibitor from whom the purchase is made be one of high standing he will probably expect a very large price for really good birds, and will also expect to be paid for, in effect, mating up a yard for the purchaser and enabling him at once to breed birds of established strain. Two birds which are suitable for mating with each other, and which a fancier would willingly sell for, say, £10 each, he would generally be unwilling to sell together for £20. In fact, we know several leading fanciers who will not sell mated-up yards at any price. There are, of course, some who will honestly do so, and there are others who will pretend to do so, and then sell birds which they well know are badly suited for breeding with each other. A further difficulty presents itself in the fact that a sub-strain started in this way must have been largely in-bred in the hands of the original breeder, and the purchaser can hardly ascertain with certainty the extent to which this in-breeding has been carried, or the actual mutual relationship of the birds purchased by him.

Purchasing sittings of eggs from a well-known yard is merely another form of the method of beginning already referred to. It of course is not open to the same objections as to cost, but it is open to the latter objection as to uncertainty how far the original stock may have been in-bred, &c., and to the further objection that it is by no means an invariable rule amongst vendors of eggs to sell from their best stock. Some of the most celebrated fanciers

altogether decline to sell eggs for hatching; and indeed when we consider that a sitting of eggs honestly sold for, say, a guinea, may produce three or four birds each worth £20, and that the purchaser may in this way at once obtain the strain of the seller, this refusal to sell eggs is not to be wondered at.

The second course open to the beginner is the one which is really the most advantageous if circumstances allow of it. It is to purchase, cost what they may, a cockerel and from one to four pullets as nearly perfect in points as can be procured. The birds should, as far as practicable, be entirely unrelated to each other, and the number of pullets purchased should be in proportion to the number of breeding yards which the fancier is prepared to maintain. Glaring faults of any kind must be carefully eschewed, as by the method of breeding which we are about to recommend they would certainly be reproduced in the progeny. This process will, in regard to many breeds, be a most expensive one, and it is open to the further disadvantage that the purchaser must not expect, at least in the first year, to obtain any adequate return for his expenditure. It is true that as a general rule it is better not to breed from a cockerel mated with pullets, but in starting a strain the short life of the birds renders such a course almost indispensable. A cockerel and one pullet is sufficient to begin with; but we should recommend, with a view to the permanent maintenance of the strain, that at least two pullets should be purchased. As the method of breeding is equally applicable whatever the original number may be, and as in the case of Pigeons only a pair can be bred from, we shall proceed upon the footing that the start is made with a cockerel and one pullet, or a pair of Pigeons.

The third course open to the beginner is to purchase birds of fair quality at moderate prices, and by judicious breeding and artificial selection to work up to the standard. This is the course which we were through circumstances compelled at first to adopt, and although it is rather a tedious process, it is still a very interesting one. It does not, however, produce at first any adequate return for the time and trouble bestowed. It is, in regard to the established breeds, a going over again of ground which has been already well trodden; and we should therefore recommend such of our readers as cannot afford to purchase really good birds of the established breeds, rather to take up the newer and less known breeds in which the points have not been so firmly established, and to do for them what the leading breeders of the established breeds have already done for their favourites.

(To be continued.)

### SUCCESSFUL POULTRY KEEPING.

MR. WALKER has kindly furnished us with the following return of the number of eggs laid each week by "L. D.'s" White Dorkings. It will be remembered that from a stock of two hens and ten pullets to start with, "L. D." had last year 1984 eggs, which we set down as 165 eggs per hen. It appears, however, from Mr. Walker's letter with the returns that some of the pullets hatched early in the year commenced laying in the months of November and December. The return per hen is therefore not quite so high as we put it; but even so "L. D." has just cause to be satisfied with the laying qualities of the birds.

### EGGS IN WINTER.

YOU ask for experiences on the production of eggs in winter. I have for the past eight years kept Dark Brahmas, but in 1879 I

thought I would try a cross, so in October of that year I purchased a dark Dorking cockerel which I mated with eight of my Brahma hens. During the month of April, 1880, I set five hens with thirteen eggs each. The result was that in May I had forty-five chickens. In August I selected fourteen pullets uniform in colour, &c., and sold off the remainder. The earliest of the fourteen pullets commenced laying on November 14th. In November they laid 43 eggs; in December 210; in January 129, and in the present month they have laid up to date, February 12th, 77, thus making a total for the three months of 459. The weather in January was anything but favourable for the production of eggs. We had continued frost from the 8th until the 28th; the thermometer registered 30° of frost on two nights. The roosting house is a small roughly built house with sheltered yard for run. The food I use is barleymeal or sharps given warm in morning, scraps and bones broken up small for their midday meal, with Indian corn for their third meal. They have skim milk to drink when it can be spared. Some of my neighbours have fifty or sixty fowls, all mongrels, and have had no eggs all the winter. How is it?—JNO. CAMPBELL.

### TOY PIGEONS—THE SWALLOW.

THIS pretty variety in its present distinct form has, we believe, been produced within the last thirty-five years. We do not find it mentioned in "The Dovecote and Aviary," published in 1851; but Mr. B. P. Brent in his little book, which was written about 1855, from his large knowledge of German lofts gave an accurate account of it. He says, "They are generally called Swallows, which name they derive from their plumage, especially the Blue ones, much resembling that of the Tern, a small species of Gull, which is also called the Sea Swallow." We cannot, however, help thinking that its name must be due not so much to its plumage as to its flight, which is most peculiar, and exactly like that of the Tern. The form of the Swallow is Trumpeter-like, and it undoubtedly has some Trumpeter blood; indeed, we have seen Pigeons in old pictures somewhat between the modern Swallow and the Trumpeter. The Swallow is, however, a much smaller and lighter bird. Like the Trumpeter it has a hood or shell of inverted feathers at the back of the head, and has feathered feet and shanks.

Its plumage is of white and some one colour clearly defined, like the Turbit, though the markings of white and colour respectively are very different. The coloured parts are the whole of the head within the hood, which must itself be white, the wings and the foot-feathering. It is to be remarked in Mr. Brent's words, "Respecting the wings, they must be wholly coloured; but the scapular feathers that overlay the shoulders are white, giving the coloured wings a narrow appearance, which is regarded as a point of much importance;" also that "the feet or slippers are coloured only from the heel or hock-joint downwards, the trousers or feathers hanging down the legs or thighs being white."

The head of the Swallow, and its beak, is rather long and like the Dovehouse Pigeon, the upper mandible dark, and the lower light.

The coloured parts of Swallows are of various colours—red, yellow, black, and blue—the latter colour sometimes with black bars on the wings, and sometimes with plain blue wings, in which case the flight feathers are of a darker shade of blue. One of the chief beauties of the breed is that its colours are found of great soundness and richness; we have often passed on at the great shows from the Turbit classes to the Swallows, and have wished that the former could be found of as glossy black or as sound yellow as the latter. Of course the markings must be very clear and defined; and here we fear, especially in the case of the coloured head and white hood, the hand of the improver is sometimes busy. The foot-feathering should be as long and thick as possible. "Fairy Swallows" are of Swallow form but with different combinations of colour—e.g., some have plain white heads, some white wings with coloured flights, some spots on the forehead, but they are scarcely worth notice.

It is many years since we first saw a collection of Swallows at the Peristerion meeting in Great Queen Street, and were charmed with them. They were exhibited by the late Mr. Matthew Wicking. His cages were crammed with them, all good and uniform, and the sight was a beautiful one. Probably there were no individual birds quite up in exhibition points to the present lovely specimens shown by Mr. Bulley or Mr. Tedd. Subsequently Mr. Wicking was kind enough to present us, though personally unknown to him, with a bird to mate with one we procured from Germany, and we bred Swallows for several years, though not for show. They are excellent breeders, make good nests, and tend their young carefully. They are hardy and active on the wing and

thoroughly suited to a country place, where their variety of plumage and elegant flight can be seen in the open air.—C.

### OUR LETTER BOX.

**Eggs and Poultry Musty (J. C.).**—We have never known Maize to cause mustiness in eggs or poultry, and imagine that it is in your case caused rather by something wrong in the place where they are kept. Eggs will get a musty flavour from being kept in musty straw or hay, or sometimes from being kept in a damp place. The same remark would apply to dead poultry.

**Egg Tester (J. G.).**—Egg-testers can be had from any of the incubator makers. Messrs. Christy of 155, Fenchurch Street, supply a simple and effective one. Mr. Alfred Perry of Cogenhoe Farm, Northampton, also sells a rather more expensive article. We never find it necessary to use an egg-tester, as by closing the first finger and thumb round the egg lengthways, and then holding the egg between the eye and a strong light, the fertility or non-fertility can be easily ascertained. By giving the egg a slight turn with the fingers of the other hand the movements of the germ which floats at the top can be seen at a very early stage.

**Fowls with Cold (Idem).**—Separate the birds which are affected from the rest, and put them in a dry and rather warm place. Put a few drops of sulphuric acid and a few drops of nitric acid in the drinking water, adding a little sugar to make it palatable. Feed on soft food mixed warm and seasoned with a little cayenne pepper. Wash the nostrils with McDougall's fluid carbolate diluted with water, but take care it does not reach the eyes. If the birds be not better in a few days write again. Do you pay proper attention to the housing and cleanliness of your birds? We shall be pleased to have the accounts you speak of.

**Shell-less Eggs (D. Jackson).**—The soft eggs dropped by your birds intimate that their egg-organs are over-excited. The food you give them is much too stimulating—Indian Corn, Barley, and ground Oats. Omit the first-named entirely, and give the Barley and Oats on alternate days, and mashed Potatoes instead of one feeding of corn daily. Give them a daily supply of Lettuce leaves, and have a heap of bricklayers' limy rubbish that they can visit whenever they please.

**Poultry Farming (Hortus).**—We cannot recommend you in your circumstances to invest your capital in poultry farming. There are no doubt people in various parts of the country who earn a living by the rearing of poultry and Ducks for the market, but to deal with them successfully some actual experience is absolutely indispensable to success. The return in eggs varies so much in different birds, and in the same birds under different circumstances, that, except with the very best management and with birds selected and bred expressly with a view to laying purposes, success is very difficult of attainment. You might combine, say, the growth of Grapes with the rearing of early chickens in the vinery for market with profit. We did know of a case in which such an undertaking showed every indication of success, but unfortunately the death of the proprietor put an end to the experiment. Should you determine upon making the attempt we should think that nearness to a town or city in which you could dispose of eggs as fresh eggs at good prices would be of greater importance to you than proximity to a seaport where grain would be cheap. Grain damaged by salt water is frequently injurious to fowls, and we have always found it more advantageous to use good sound grain in preference to damaged. The best pure-laying breeds are Spanish, Minorcas, Andalusians, Leghorns, and Hamburgs, but the Leghorns and Hamburgs lay as a rule rather small eggs. You will, we think, find a good deal of information which would be useful to you in our article on "Eggs in Winter" in last week's number.

**Parrot Eating Feathers (Passaget).**—We think it very probable that the sulphur remedy mentioned by Col. Taylor on page 122 would be beneficial and is worthy of trial; judiciously given the sulphur could not do the bird any injury.

### REMARKS.

- 6th.—Very fine and dry, bright sunshine from sunrise to sunset.  
 7th.—Cold, with high gusty wind; snow in forenoon, which quickly disappeared; rain after 5 P.M.; heavy at 8.50 P.M.; lightning from 10.30 P.M. to 11.30 P.M.  
 8th.—Gale during the night; stormy day, heavy showers, and sunshine at intervals; fine evening, starlight.  
 9th.—Very fine with sunshine all the morning; overcast in afternoon, rain from 5.30 P.M.  
 10th.—Very stormy, high gusty wind; heavy showers in morning, sunshine at intervals; calm in evening and moonlight; rain at 10 P.M., and wind high again till midnight.  
 11th.—Cold, with slight showers of snow and sleet, and high gusty wind during the day; evening fine and calmer.  
 12th.—Very fine, bright, clear, and cold.  
 A squally week, with very great oscillation of the barometer, especially between the 11th and 12th. Much more sunshine than for some time past.—G. J. SYMONS.

## LOOKING AHEAD.

HERE is often a great waste of time, money, and material in gardens as elsewhere owing to the neglect of a timely systematic arrangement of plans. No one is worthy of the name of gardener unless he can look twelve months ahead, and, indeed, in some respects he must be able to see much further than that. It is true that "the best laid schemes of mice and men gang aft a-glee," and that some of us need the head of a Von Moltke to be ready for all emergencies; but there is little doubt that the actual committing of plans to paper is a very great help to a student of any kind, for even when such plans end in failure there is generally an opportunity of tracing the cause of the misfortune, and that often brings knowledge for future use which is not easily picked up in any other way. A very busy time both for heads and hands is fast approaching, and anything which can be done now to lessen the coming strain on the nervous system should be grappled with manfully; for although the imagination has to do more now than when the actual contingencies are before us, and it is consequently much harder work, yet there are fewer calls for brain work than there will be in two or three months time, and it will do us good to get rid of a little of the rust which has accumulated during the dull season.

Plans of flower-garden arrangements if not made at the proper time—i.e., during last August, should be completed immediately, with an estimate of the number of plants required of each sort, and these plans and estimates should be accessible to whoever has the responsibility of providing the stock of plants. For the kitchen garden, too, a rough plan should be drawn out every season, showing the proposed site for every spring crop, and when a second crop has to follow in the same year that should be shown too. There are many things to be considered when arranging vegetable crops, some of which are change of crop, suitable position for some important crops which will not do everywhere, condition of the soil as to richness, texture, and friability, convenience of certain positions for making additions to the soil, which are essential to some crops, &c.

Although gardeners generally acknowledge that the rotation of crops is sound in theory, we are often to a great extent obliged to ignore it in practice, and as failures in vegetable crops, excepting in such seasons as 1879, are almost unknown, we are not likely to alter much in this respect. Personally I believe the rules by which theorists would regulate rotations of crops are much too severe, and that when land is well cultivated in all other respects there is no great harm in growing

plants of the same natural order year after year on the same plot, excepting such plants as are allowed to produce seed, and those which are subject to some disease or insects likely to be preserved in the ground. I do not wish to underrate the good services chemists and physiologists have rendered in teaching us how plants are built up, and of what they consist; but as we find their facts of one day have sometimes almost turned to fables the next day, we may be excused for not relying too exclusively on theory. I hold that change of crop, excepting in the cases I have mentioned, is not so great a matter as finding a suitable position for certain important vegetables which are a little fastidious in their likings. For instance, I can show one corner which has had early Cauliflowers succeeded by late salading annually for the last dozen years, and possibly Cauliflowers may have been grown there for half a century before I saw it; still it always produced my best and earliest Cauliflowers, and no amount of theory will induce me to change it. Another plot generally has early Peas followed by Snow's Broccoli, thus going against even the remnant of the rotation theory, which I hold to be sound, but I cannot find a better position for either crop, and they generally succeed admirably, especially the Broccoli.

Many other instances could be brought forward where the ground produces the same sort of crop year after year in a most satisfactory manner, which would go far to prove that nothing is taken from the ground by the quick-growing green vegetables which cannot be restored immediately by the liberal application of good dung and an occasional dose of lime or charred refuse, and that when this is done Cabbages will do as well after Cabbages as they would after any other crop. But sufficient has been said to call attention to this part of the subject.

On the other hand, the act of producing and maturing seeds makes a very great call on the fertilising ingredients of a soil, possibly more so on some soils than others. When I have saved a little seed of any kind hitherto, I have afterwards been able to point out the place of its production to a foot either way for two or three years, but lime and burned clay have been liberally applied of late, and that may possibly make a difference in this respect. I am confident our farmers do not fully appreciate how much the production of seed takes out of the land; and were I to start farming, one of my first experiments would be to top the flower shoots some time during spring of the grass which was intended for hay, for which simple operation I should expect to be rewarded in the shape of a double crop. This might possibly be done by setting the ordinary long grass mowing machine up about 6 inches from the ground. Just compare the weight of grass we take off our lawns in the course of a year with that the farmer gets off a piece of ground the same size, and this, too, while he gives heavy dressings of manure, and we give little or nothing. I am aware that grass for haymaking must have more substance in it than the grass on our lawns possesses, and this I maintain it would have were it topped at the right time and right distance from the ground, and then be allowed to grow again till the flowerstems reached a certain stage.

During the last two seasons hay has taken more than usual out of the ground, because both hay seasons were wet and much of the grass was unavoidably left standing till the seed was quite ripe. I know of one patch which was left for hay in both these seasons. In 1879 it was cut very late, after

most of the seed had fallen, and although it had a liberal dressing which included lime, and the soil itself is a good substantial one, yet there was nothing at all worth cutting on it last year.—WM. TAYLOR.

### ROSES ON THEIR OWN ROOTS.

IN an article bearing on the above subject at page 125 "Y. B. A. Z." takes exception to a few remarks of mine with respect to the slow process of producing Roses from cuttings. Perhaps "Y. B. A. Z." would not have questioned my assertion if I had worded it thus—"To produce Roses 'in quantity' on their own roots is a very slow process." Your correspondent furnishes a very strong argument in favour of my assertion by the experiment he made in 1879, when he "inserted between four hundred and five hundred Rose cuttings, and the year following he had nearly fifty plants large enough for transplanting." If this was all "Y. B. A. Z." obtained from, say, 450 cuttings it is indeed a very slow process, and "Y. B. A. Z." need no longer "wonder it is not more adopted." In comparing the two methods of propagation your correspondent, respecting the Manetti stock, says, "Sometimes they are budded the year after planting, but this is not the ordinary plan." "Y. B. A. Z." is decidedly in error here, as it is a most unusual and unnecessary delay not to bud them the first year after planting, while I know of some who plant Manetti cuttings in nursery rows in the autumn and bud them the following summer.

Respecting "A ROSARIAN'S GARDENER'S" observation on the same page, I am very pleased to find an instance in favour of Maréchal Niel thriving on its own roots, albeit time is young with the plants at present, which undoubtedly received very special treatment in the way of heat, moisture, and feeding during the growing season; and although your correspondent may appear warranted in auguring favourably from their present appearance, they may nevertheless prove a mortifying failure.

I certainly cannot lay claim to having struck "hundreds of Maréchal Niel which in due time produced hundreds of flowers," and would most respectfully ask "A ROSARIAN'S GARDENER" what became of them, and how long they lasted. My own experience, however—which I do not look upon as infallible—has taught me the very opposite. I was furthermore confirmed in this a short time since when visiting a large establishment where flowers are grown for cutting expressly to supply a branch of the establishment at one of the most fashionable seaside resorts in the south. In looking through the Rose houses I chanced to remark to the foreman that out of numerous inquiries as well as from my own knowledge I had never found the Maréchal do well and prove satisfactory for any length of time on its own roots. He instantly drew my attention to a plant, the last one of a batch they had on their own roots, and he at the same time assured me they had never done any good. A case of the kind was never better exemplified, as there were worked plants of the same kind in the house in the most luxuriant health. They had proved highly satisfactory, and so far as appearance went they were likely to do so for a very long time to come, while the plant in question was in a state of advanced decrepitude.—OXONIAN.

REFERENCE has been made on pages 125 and 126 to the young plants of Maréchal Niel here, and I willingly give the details pursued in their cultivation. Before doing so, however, I must say I do not agree with "OXONIAN," on page 86, where he refers to the production of Roses on their own roots as a slow and tedious process. From my own experience I do not consider it a slow or tedious system; for example, take Gloire de Dijon, strike cuttings during February, grow the plants in pots for one season, and they will produce the following spring on an average twenty blooms each. Lamarque, Belle Lyonnaise, and Rêve d'Or strike as freely as the "old Glory," and all will make equally as much wood in a season, but the two former will not bloom so freely. Again, strike cuttings the same month of Catherine Mermet, Isabella Sprunt, Homère, Safrano, and others, and they will in one season make as good plants as those worked on the Manetti or Briar and sold in the autumn by the majority of nurserymen. I can go further—they will make stronger plants the following year than many of those worked upon any stock. I have invariably found that worked plants of many varieties of Teas do not grow with that vigour they do when on their own roots and are independent of the stock. The Manetti as a stock I consider useless except for the purpose of manufacturing Roses under the present system. How long will many Roses live upon it? Leave a portion of the stock above ground, and it quickly dies or makes but poor progress. The Maréchal will not do upon it. It may do well for one year, when it will have exhausted the stock and it

dies. In the majority of cases it will not live long enough for the Maréchal to throw out roots from the union and support itself. The Maréchal will thrive satisfactorily on the Briar for a few years, when it cankers at the union and dies. I have also seen it die when on the Briar when it has not cankered, but the majority die through cankering—the Briar not swelling in proportion to the Rose worked upon it. I believe there is ample proof in the country if collected to prove that the Briar is not a suitable stock for the Maréchal Niel, its life upon it is not long enough.

To return to the plants referred to here: they are now in 10-inch pots, and the Maréchal Niel has grown stronger than the Gloire de Dijon rooted at the same time and grown exactly under the same conditions. Three of the Maréchals scarcely vary more than 6 inches in the length of shoots, which are over 25 feet in length. They are now breaking into growth, and I counted on one plant thirty-three flower buds visible, and there are between sixty and seventy breaks in all at the present. The remaining, say thirty-three, are scarcely forward enough to see the flower buds yet, but without doubt many of them will flower. The smallest plant rooted at the same time has made over 15 feet of growth. Gloire de Dijon did not attain more than 15 feet, but branched and made a greater number of shoots.

Young shoots quite soft were selected for the cuttings of the Maréchal Niel about 2 inches in length, taken with a small heel from not extra strong shoots. The "Glories" were short pieces of the same length cut to a joint, no heel, quite green wood not nearly half ripened, and in this condition the majority of Roses strike well. Six-inch pots were prepared and well drained, filled with loam and sand, three parts of the latter to one of the former, to within an inch of the top, which was all sand. No foliage was taken from the cuttings, not even the bottom leaf. They were inserted as thickly as possible, well watered, and plunged in the propagating frame. The frame was not opened for several days until it was thought watering might be necessary. The admission of air is, I believe, the cause of many Rose cuttings damping off when young tender wood is employed. They quickly callused and the top growth of the Maréchals began, but no harm resulted, as some say is the case when growth takes place at the top before roots are formed. They rooted as quickly as Pelargoniums and nearly as freely. They had the aid of slight bottom heat, and the frame stood in a temperature of 65°. As soon as roots were formed the plants were potted singly in 3-inch pots and returned to the frame for a week or ten days. The growths that had started at the top were pinched and roots were made quickly. The plants were gradually hardened and placed under the shade of some Cucumbers for a few days. They remained in this temperature (65° at night) until they attained about a foot in length, which was in a very short time. Each was supplied with a stake 3 feet in length, and the plants placed in 6-inch pots, and in about ten days removed to a vinery in which a suitable temperature was maintained to gradually harden them for cooler treatment. In a short time the plants were removed to the Rose house and placed at one end of the side stages. The strongest were placed in 8-inch pots and given longer stakes. They soon became too large for the position they were in, and the roof was already too full of Roses trained under it. The greenhouse was selected as their future position, and to make room for them some less worthy objects were thrown away. When removing them towards the end of June they were 4 or 5 feet in length, some more. They were all placed in 10-inch pots to save disturbing them again, but they were not really ready for this shift, as the pots were not so full of roots as I should have wished before placing them in such large pots. A severe check ensued, and growth was brought to a complete standstill. At first I thought it had been occasioned through the operation of potting; but my foreman, to whom the work was entrusted, assured me that could not be the case, as he had done them all carefully himself. Being a trustworthy man his statement on that point was sufficient, and we looked in other directions for the cause, which we never found. To our surprise the whole started strongly from the base, some just above the soil, others below it. The former shoots grew but little more. Nothing in the end was lost by the check or small rest they enjoyed, for they made rapid progress and grew with such luxuriance as I never saw young Roses grow before. The Maréchals reached the top of the house before stopping, a distance of 24 feet from where the pots were standing, and three of them grew 2 feet too long for the house and had to hang down.

The soil used for potting was rich fibry loam, a seventh part of old Mushroom bed refuse, consisting of half leaves and horse droppings, and a 6-inch potful of bone dust was added with plenty of sand to keep the whole porous. No stimulants were given during the season, but plenty of water while growing. The plan's were liberally syringed to keep down spider, aphides, and

mildew with the softsoap mixture that has been detailed from time to time in the Journal.

Two or three of the Maréchal Niels will be planted out in May in an outside border—when the spring flowers are taken off—and the growths brought through to cover the roof inside. I have now a good plant in a pot on one of "OXONIAN'S" favourite stocks, which will be planted out at once inside; its roots will have the entire run of a Peach border 60 feet long, and top growth will be trained in an adjoining house. I may refer to these Roses again at some future day.

There is a magnificent plant of Maréchal Niel on its own roots at Hooton Hall, Cheshire, under Mr. Hanagan's care, with a beautiful clean stem many feet in length, as straight as a gun barrel and as thick as a man's wrist, from which, if I remember rightly, four hundred blooms were cut last year. This fine tree is several years old, and I do not know of one to equal it on any stock.—W. BARDNEY.

#### THE "RECTOR" AND HIS CRITICS.

WHEN either "WILTSHIRE RECTOR" or anyone else can write such a new year's address as the one in the opening pages of this year's Journal, and which startled out of their "retired" mode of living such writers as Mr. Wills, brought the great thinking powers of Mr. Iggulden into operation, and set a host of other writers of more or less note to work, it is evident there is "something in it," and that the vegetable supply is a question of wide and general importance. The "RECTOR" lays it down as a cardinal point in his address "that gardening" (I am quoting from memory, not having the Journal for 6th January by me) "should be extended into the domains of agriculture," and seems to desire to convey the idea that our notions of gardening as well as our gardens are too confined.

Most of the "RECTOR'S" critics have only looked at the matter from a mercantile point of view, and wish to point out that there are already too many extensive gardens devoted to the growth of vegetables for market, and seem to discredit the remark about the town population not being able to obtain a supply of vegetables. Viewing the matter even in this business light I have no doubt that the "RECTOR" is quite right, and that in many towns people do not and cannot get a sufficient supply of vegetable food. A case in point: Last summer Tomatoes could not be bought in Sunderland or Newcastle under 6d. per pound, yet a friend of mine who had a very large quantity of first-rate quality could not get as much for them at the shops in either of the towns named as paid for their carriage! Another: A market grower near Sunderland supplied a shop with Rhubarb at 1s. per bundle of thirty-six bunches; price at shop 1d. per bunch, "and nothing less!" In the latter months of last year Celery was selling in Sunderland at 3d. per head; at the same time thousands of heads were despatched to Manchester at about 1d. per head! All other vegetables are much in the same ratio. So far as this neighbourhood is concerned the "RECTOR'S" remarks certainly apply, as I have no doubt they do in other towns. There does not appear to me to be such a dearth of vegetables, but there is evidently something entirely wrong in the manner and means of their distribution, which remark appears to be borne out by the fact of so many of your correspondents giving direct and conclusive evidence that so much of their produce does not pay them to take to market.

I do not attempt to suggest a remedy. Someone much more conversant with the subject will have to take it up, if it is worth while. As I see it, the vegetable supply is one of the most important matters of our domestic economy at the present time. The "RECTOR" makes a laudable effort to induce the poorer people to partake of more vegetable, and consequently cheaper food; but practically in many places this is impossible, for many reasons. In the town near which I live it would be difficult for the ordinary working man to obtain many vegetables, owing to their high prices; and moreover, very few of the wives or daughters of our labouring classes, and even the artisan class, are able to cook a dish of vegetables; nay, they do not even know what many of them are. Beyond Potatoes and Cabbage, always plain boiled, or a few leaves of Lettuce soaked in bad vinegar, very few of the "women of the people" have any very distinct ideas about vegetarianism.

Then there are all the stupid prejudices inherent in the race to remove. Few Englishmen will forego their steak or chop, even if they are certain that they will be as much benefited by a savoury stew of Onions and bread, or a dish of Apples and rice, which do not cost quarter as much. When the excessive extravagance in the use of so much animal food can be fully impressed upon the masses, the proper uses and values of fruit and vegetables as articles of food thoroughly understood and appreciated, and above all the supply of them so regulated as to be as readily

purchased and at as uniform a rate as a pound of flesh or a three-penny loaf, then, and not till then, will the worthy "RECTOR'S" ideal "future of gardening" be attained. To attain this much-wished-for end we must have more of such writing and learning as that alluded to, not only in the *Cottage Gardener*, but in all papers that are read by the masses. Two years ago, after a careful trial of vegetable diet, I endeavoured to set forth its merits in a discussion then being carried on in a local contemporary. My experience in the matter was not at the time at all pleasant, but I have the satisfaction of knowing that since then some of my most earnest opponents are now confirmed vegetarians and teetotallers. Eagerness to assist the "RECTOR" in his good cause has impelled me to take part in the present discussion.—PETER FERGUSON, *Mere Knolls, Monkwearmouth.*

#### HOYA BELLA.

ONE of the most charming little plants for the stove is *Hoya bella*, an umbel and spray of which are shown in the annexed woodcut. It is a diminutive and delicate counterpart of the

Fig. 31.—*Hoya bella*.

well-known *Hoya carnosa*, and, like its equally pretty relative *H. Paxtoni*, is much better suited than the old species for a shelf near the glass in the stove, as they are both dwarf and compact in habit with small umbels of flowers. These two species have long been great favourites with me, and I find they are, when well grown, invariably admired. Similar treatment suits them both—namely, a compost of peat, sand, and finely broken charcoal, the pots being thoroughly drained. A warm position in the stove is required where the plants can be fully exposed to the light, or otherwise they are liable to become sickly and unsatisfactory.

*H. bella* was discovered by Mr. T. Lobb in the Taung Kola Mountain, Moulmein. From him Messrs. Veitch & Sons obtained it, and at their Exeter nurseries it first flowered in the summer of 1848. It has thus been in cultivation more than thirty years, and might be expected to be in almost every collection of plants; but such is by no means the case, for I know many gardens of

more than ordinary pretensions where it is not grown. This neglect of a beautiful plant is strange, for when its delicate wax-like white flowers with their rich purple central rays are fully expanded, the plant is unrivalled except by its near relative *H. Paxtoni*. The neat trusses of flowers are invaluable for cutting when something particularly choice is required.—L.

#### EARLY TOMATOES.

UNDER the above heading Mr. Muir, on page 108 of your last issue, had a very interesting article. He says that the present is a good time to sow the seed for an early crop of Tomatoes, and he is right if early and late crops are all that are required.

If Tomatoes are so highly esteemed as they are said to be, why not have them all the year round? They are easily grown, any ordinary rich soil will suit them, and with careful attention to tying, pinching, and watering there is no difficulty in growing them successfully.

We are cutting fruits from our early crops now, and have been doing so since the beginning of the year. For an early crop of Tomatoes I recommend plants raised from cuttings taken in August in preference to seedlings, as I find that cuttings fruit more freely. Their final shift may be either into 10-inch pots or into boxes of a suitable size. They will flower freely, and by the end of October plenty of fruit will be formed for a crop; and when the plants are introduced into a house where a temperature of from 50° to 60° can be maintained during the dull months of the year the fruits will swell rapidly, and by the beginning of January will give a plentiful supply of good Tomatoes.—J. M. K.

#### THE EFFECTS OF ELECTRICITY ON VEGETATION.

(Continued from page 128.)

**MILDEW.**—It has been pointed out that plants consist of two different conditions, one taking the stain and the other resisting it; the one taking the stain belonging to the root or supply system, the other to the oxygenated or product class. Procure a leaf spotted with mildew, and dip it for an instant into the dilute magenta stain, and all the mildewed part will become deeply dyed in opposition to the unaffected portions. This at once proclaims the fungoid growth to belong to the root section. Take a thin slice out of any part of a Mushroom, or any of the Toadstools, and it will take the stain very readily, the gills least so, but all showing the same tendency. But the Mushroom or the Toadstool is only one part of the fungus, representing the flowering or fruit portion of the true plants; the other, or more mischievous division, is the creeping root which usurps the nutrient fluid of the victim upon which it feeds. This root portion, or "spawn," is composed of single elongated cells attached to each other lengthwise in strings, and continually extending and creeping along amongst the cells, choking up the intercellular spaces and appropriating their nutriment. It is a noticeable point that these growths seldom or never penetrate the cells themselves, but are almost if not entirely confined to the intercellular spaces and divisional walls, as may be seen under the higher powers of the microscope in well-prepared specimens. Now this "mycelium," or spawn, may exist for an almost indefinite period without advancing to fructification, and it is only when the specially favourable conditions for this ultimatum are brought into existence that the Toadstools and Mushrooms appear. There is one peculiar feature pertaining to fungi that separates them completely from the general bulk of vegetation—they are altogether entirely destitute of chlorophyl grains—the green colouring matter of the leaves of Ferns and flowering plants, &c.; and by the absence of this, and there being no other substance corresponding with or replacing it, these organisms are thus demonstrated to be non-polar, or in other words, to be associated with, and to partake of the particular electric condition of the part to which they belong. In referring to the experiment with Cress seed (page 266, last vol.), those seeds which were around the positive, or oxygen-attracting electrode, were the first to germinate; but they very soon died and blackened as if burnt, which in fact they were. They also germinated heels upwards, and ultimately became infested with the mycelium of a fungus. With regard to this blackening process in the case of the seed, it was purely an electrolytic proceeding. Dip a match-stick or a piece of straw into concentrated sulphuric acid, and it will instantly become charred in a similar manner. The oxygen of the acid at once seizes upon the hydrogen of the albuminous compound, and so liberates the carbon in the state of charcoal. With the battery the oxygen is provided by the electrode. But then the air immediately in contact with and surrounding the seeds being rendered electro-negative, or reversed from its normal state

and made to correspond with that of the earth, the radicles or rootlets were also made to follow the same order, and to push their way into the negative as usual, which in this instance proves to be the air instead of the earth, and hence their inverted position. Now, as the electrolytic action will still be going on after the death of the seed, and not ceasing with this change, the albuminous material of the seed will also be undergoing further changes and necessarily be forced into some other form.

Around the negative electrode the seeds were longer in germinating, but when they did so they were well plumped out and exceedingly bright-skinned; they grew on healthily for some little time, or so long as the required nutriment contained within themselves was unexhausted; but when this supply ceased and there being no root-action to replenish the store, growth came to an end. These results fully demonstrate the dependance of the two conditions upon each other, one to prepare the food and the other to convert it into growth. Hence, had the two actions been simultaneously or alternately exerted upon the same seed, one would have furnished the supply and the other converted it into growth. But as the negative growing action was absent from the positive electrode we have the positive forcing the nutriment it goes on forming, into a special growth of another kind—the cellular threadlike mycelium of a "fungus."—W. K. BRIDGMAN, *Norwich*.

#### THE METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on Wednesday the 16th inst., at the Institution of Civil Engineers, Mr. G. J. Symons, F.R.S., President, in the chair. J. L. Bell, F.R.S., J. Bernays, A. W. Blyth, J. Church, F. W. Cory, S. Cutler, T. L. K. Edge, C. Horsley, W. J. Howard, C. Kelly, M.D., G. Lingwood, W. Macgeorge, Capt. J. P. Maclear, R.N., A. Rigg, and H. C. Stephens, were elected Fellows of this Society. The following papers were read:—"Relative Humidity," by Charles Greaves, M. Inst. C.E., F.G.S. The object of this paper was to show that the term "Relative Humidity" was frequently the cause of misunderstanding, and that it was desirable that some other tables with a more correct denomination should be used in order that reliable values of this factor in our climate should be recorded. "On the Frost of January, 1881, over the British Isles," by William Marriott, F.M.S. The author pointed out that the severe frost of the 7th to the 26th was remarkable for its unexpected appearance, its long continuance, and its sudden breaking up. The weather during the first week of January was comparatively mild, but frost set in over the north of Scotland on the 5th. The author then gave the lowest thermometrical readings from about three hundred stations in the United Kingdom for each day of the frost, which were plotted upon diagrams clearly showing the relative severity of the weather experienced in each district. The lowest readings were, 15° at Garstang on the 16th, 22° at Blackadder, 16° at Kelso, 15° at Stobo, 11° at Thirlestane Castle, and 10° at Melrose on the 17th. Reference was also made in detail to the rivers and lakes which had been frozen over, and to other incidents proving the remarkably low temperatures which had occurred. Some idea of the intensity of the frost may be gathered by the fact that in the south of Scotland the temperature fell below 10° on more than eleven occasions, below 20° on nineteen occasions, and was below 32° on twenty-five to twenty-nine occasions. In the London district readings below 10° occurred on two or three days, below 20° on ten days, and below 32° on twenty days. In Ireland temperatures below 10° were registered on six or seven occasions, below 20° on twelve or fourteen occasions, and below 32° on twenty-two to twenty-four occasions. No place in the British Isles was exempt from the frost; even at Scilly the temperature was below 32° on three days, the lowest being 29° on two occasions. The winter seaside health resorts afforded no protection from the frost; at Penzance the temperature fell below 32° on ten occasions, at Torquay on eleven occasions, and was below 20° on six occasions; at Ventnor it was below 32° on nineteen occasions, and below 20° on three occasions; and at Bournemouth it was below 32° on twenty-three and below 20° on ten occasions. The heavy falls of snow prevented the frost from penetrating far into the ground, but where the snow was cleared away the temperature of the soil fell considerably. A diagram was exhibited showing the mean temperature of January in the neighbourhood of London for each year from 1774 to 1881, from which it appeared that the low mean temperature of 31.6° for last month had only been surpassed on five occasions, and that the three years 1879-81 have been very cold, the mean for this period being only 32.2°; there is no instance during the past hundred years of any three consecutive Januarys having so low a mean temperature.

• **THE BEST LATE POTATO—IRELAND.**—The question is whether such a list of three hundred varieties as Mr. Shirley Hibberd publishes (referred to in *Journal* page 133), does not mystify instead of enlighten. To the general cultivator, would it not be more important to know which are the best earliest, intermediate, and late varieties? But then I may be asked, Have they not a tendency to degenerate? If the seed is not properly selected, and the

worst is planted, as sometimes happens, and on the same soil, there can be little doubt that the answer must be in the affirmative. I conducted experiments at the Government Training Agricultural College at Glasnevin about twenty years since, and except one or two there are few of the then varieties now in general cultivation. As a matter of fact there is a tendency to degenerate, but the degeneracy is mainly owing to want of selection. To all my inquiries in Ireland at present, and I have a short time since been through the four provinces, the best general crop Potato is the Champion.—W. J. M., *Clonmel*.

#### CULTURAL NOTES ON GLADIOLI.

MUCH has been written concerning the successful cultivation of Gladioli, but I venture to offer a few hints upon them, having grown them with success for some time. An open warm situation sheltered from high winds should be chosen. Apply manure liberally, and trench the ground about 2 feet deep in winter or early spring. I do not approve of the situation being changed every season; on the contrary, when you have been at the trouble of having the ground well manured, let the Gladioli remain there for a few seasons. To secure a continuous display of flowers during the autumn months plantings should be made from the beginning of March to the middle of May. The corms should be planted 1 foot apart and at least 6 inches deep, covering each with prepared light soil. In some parts of the country where the atmosphere is dull and soil cold in the months of March and April I advise potting the corms singly in 5 or 6-inch pots, employing a compost of rich loam, well-decomposed manure, and a little sand; place them in a greenhouse or cool frame, where they will be safe from frost; attend carefully to the supply of water and in ventilating, and by the end of May all danger will be past. The plants by that time will be about 6 inches high. See that they are well hardened off, and plant them out in the prepared ground. Those that are planted out in March and April in more favourable situations will be well forward. After the plants are about 6 inches high the ground should be covered with half-decayed manure or cocoa-nut fibre refuse. Apply water liberally during dry weather. Stake the plants carefully as they advance in growth, and as soon as the flowerspikes appear weak liquid manure may be advantageously given once or twice a week. Successful cultivation depends in a great measure upon liberal manuring, deep planting, and plenty of water during the growing season.

Gladioli are invaluable for conservatory or greenhouse decoration during the autumn months. For this purpose the corms should be potted about the middle of March in 6 and 7-inch pots, using a rich soil; protect from spring frosts; in May plunge the pots in an open, warm, sheltered situation; and be careful in supplying water, especially during dry weather. Stake the plants carefully as required. As soon as the flowerspikes appear a liberal supply of liquid manure should be given once or twice a week. When the flowers begin to show colour the plants should be removed to the greenhouse or conservatory.—W. MUIR.

#### PLANT APPLE TREES.

I NOTICED in his speech at the dinner of the Chippenham Agricultural Society Sir Gabriel Goldney stated that "he saw from the agricultural returns no less than a quarter of a million of acres of land had, during the past fourteen months, been turned into orchards and market gardens."

Permit me, as having paid some attention to the subject of fruits both theoretically and practically, to say a word on this subject, for I verily believe there is benefit to be derived from the cultivation of fruits, particularly of Apples; benefit to be reaped in a few years by the owner and tenant.

Go where one will American Apples are in fruit-shop windows—Red Baldwins show their rosy, and Newtown Pippins their olive green cheeks. I am told that each year more and more Apples from America are in the market. This surely need not be; for Apples, if of the right sorts, and the trees of the right age, are in average years one of the surest of crops. But more than half the Apple trees in England, save in the cider districts, want grubbing up; they are too old, they are "have beens," but their day is over. The miserable, gnarled, bent, blight-beset lichen-covered trees one sees in numbers of orchards have for years been only fit for firewood. Again I would say, Plant Apple trees on arable land; the standing crops preserve the young trees from mischievous boys, and the young roots are uninjured by entangling grass. Mind at the same time the plough does not go too near the said roots. The land can be regularly cropped until the trees grow of considerable size—a double gain,

as there will be two crops, and also the Apples cannot be so easily pilfered—then after some years lay down the land in grass. Another hint: Mind and plant, but not bury the trees. As to soils, the Apple certainly prefers a sandstone, while the Pear rejoices in a calcareous soil; still, any good loam will do. The situation should be to the south or south-west, and a protecting wood to the east and north is of value in preserving the blossoms from the spring frosts. As to purchasing trees, I would say, Buy of the large nurserymen only; they are sure to sell you trees true to name—this is very important, and they are able to sell at a reduction. It would pay landlords to be the purchasers. If my plan be judiciously followed there need not be in a dozen years a single Apple sent to us from America.

On the subject of Apple culture I have consulted one of the very first and highest authorities in England. His reply to me is as follows—"I think your suggestion of planting far more land with Apple trees is a very good one. I know there are thousands of acres in this country let at 30s. to 40s. an acre that would bring £5 after being planted ten or twelve years with fruit trees of good and suitable sorts. Of course the trees must be protected from the injury of cattle and such like damage. Below I give the names of some of the most useful and robust-growing kinds for profit, sorts applicable generally for eating, cooking and grinding, or any other purpose that the market for the time may prove most advantageous. I would never advise planting sorts that can only be used for cider, because the sale is so limited; and it is a well-established fact that the highest flavoured Apples make the richest cider—such as Golden Pippin, Golden Hervey (brandy Apple)—in short, all such as have enough malic acid, and this is readily tested; those that turn brown soon after being cut with a knife are always good for cider.

"The following are good and profitable kinds:—Lord Snffield, Keswick Codlin, Cellini, Dumelow's Seedling, Blenheim Pippin, Worcester Pearmain, Ecklinville Seedling, Golden Winter Pearmain, Beauty of Kent, Malster, Tower of Glammis, and Peasgood's Nonsuch."

Every word of the above I beg to endorse. I say, Plant these Apple trees and at once, for there is just time—plant carefully, almost on the soil, spread carefully the rootlets and tender fibres, do not roughly thrust the trees into holes, but use them tenderly and stake well, and sure profit will come.—WILTSHIRE RECTOR (in the *Devizes Gazette*).

#### EFFECTS OF THE FROST IN THE ISLE OF WIGHT.

"W. J. M." asks for information with regard to Veronicas, as to how they have withstood the severe frosts. There are several varieties of these shrubs grown in this neighbourhood in the Isle of Wight; in fact, Veronica Hendersoni is used in many gardens as a hedge planted in the soil by the side of walls, where the walls are used as retaining boundaries on sloping banks, which is often the case in the Undercliff gardens. I do not know whether all the forms, such as Hulkeana, decussata, salicifolia, and pinguifolia, are grown here, but in nearly every case the upper shoots and more succulent growths have suffered severely, especially where exposed to the cold winds which preceded the snow of the 18th of January, and also where the plants were not protected by the snow, which fell to more than the depth of 2 feet in this neighbourhood, and in fact all over the island on the 18th and 20th. As there was a strong south-easterly wind blowing at the time the snow fell, especially on the 18th, very deep drifts were formed, the remains of which are still to be found in some places about here (Ventnor) even now, more than four weeks after the fall. In nearly all cases the younger shoots of all the different species of Veronicas I have examined have been quite killed, and the older growth much damaged. One reason why the younger shoots have suffered so much was owing, I think, to the very open and unusually warm weather at the end of November and all December; in fact there was no frost of importance here till after the 10th of January. All the Veronicas, therefore, were still growing, and most of the varieties still in full bloom.

I am afraid many other varieties of the less hardy evergreens have also suffered much, as some of the kinds of Euonymus, especially the silver variegated variety. All the plants, too, of Eucalyptus globulus are killed, some of which at Bonchurch had survived several winters, and were from 20 to 25 feet high. There are several very fine trees of the Paulownia imperialis in Ventnor and Bonchurch which were very full of flower buds, the spikes in some instances from 7 to 10 inches long. The shoots are still quite upright and have not flagged, but the flower buds seemed so unusually forward at the beginning of the year, it is still rather a question how much they may have been injured, as in no instance could they be protected by snow; and those who, like myself, are

great admirers of the beautiful flowers of this tree, will be anxious to know whether the blooms will stand this late severe cold. In many places the flowers of the Laurustinus have been much injured, though the plants themselves seem to have withstood the cold very well. Plants of Photinia had in warmer places made too much young growth, and these younger leaves are much injured if not quite destroyed, and I fear in most cases they will not flower. Flowers, too, of the Berberis Darwinii were unusually forward, and where they were open are killed, but the plants themselves do not seem to have suffered, and young flower buds which were not too far advanced will still open when warmer weather comes. Escallonia macrantha has suffered much in the same way, though I fear in some cases more severely.

A great many of the houses and villas in Ventnor and the neighbourhood are covered with plants of Passiflora caerulea, which had an unusual amount of the orange-coloured egg-shaped fruit hanging from their trailing stems; in some of the more sheltered places there were flowers and buds still on these plants at Christmas time. These have also suffered severely, though it is to be hoped that they will all make fresh growth from the base. In one garden at St. Lawrence there were some very fine bushes of the Mediterranean Heath, the Bruyère, from the roots of which the so-called briar pipes so much in vogue among smokers are made. These plants were quite crushed down with the weight of snow, but the snow protected them from the frost, and though the flowers were injured the plants themselves will recover. The Bay trees, Aucubas, Arbutus, and Ilex all seem to have withstood the frost very fairly, though in some instances the boughs of the Ilex were broken from the weight of snow. The change of temperature was very sudden, as even early in January many of the bedding plants, such as Lobelias, Geraniums, and Calceolarias, were still partially blooming, and on the 3rd of January in a garden at Ryde I saw a Rhododendron in bloom and Camellias ready to open.—C. P. P.

#### ZONAL PELARGONIUMS FOR WINTER FLOWERING.

HAVING read in the Journal during the last few weeks of the good qualities of the double-flowering Pelargonium Guillon Mangilli for winter flowering, I should like to bring to the notice of the readers of the Journal a valuable single-flowering Zonal—viz., Charles Smith, raised, I think, by Mr. Pearson. The colour is a brilliant dark crimson, a colour that strikes the eye amongst all the others, and is most effective. I have tried a great many varieties, but I consider this one by far the best for winter or summer flowering. I have had some plants of it in flower from early spring up to the present time without intermission, and still blooms are coming. It has several good points—viz., hardiness, free flowering, immense trusses, brilliancy of colour, good substance, and compact growth. My greenhouse has been kept most gay up to the present time with it, and has been admired by all who have seen it. If I could only grow one sort it would most certainly be this. The gardeners round here admit they have never seen one to equal it for winter flowering, and anyone who has seen it need never be without flowers all through the year.—P. R., Wigan.

[We presume our correspondent means Charles Schwind, which was raised by Mr. Pearson and answers to the description given. It is very rich in colour and flowers profusely.—EDS.]

#### GLAZING WITHOUT PUTTY ABOVE THE GLASS.

IN reply to numerous correspondents asking for further information to that given at page 550 of your last volume, I hardly know what more can be said, only that an error of mine or the printer's occurred there, which is certainly misleading, as it reads that the "wood" is to be dressed off level with the glass, "putty" being the word intended. I have only to repeat that the rebate in the rafters and sashbars is prepared in the ordinary way—i.e., ploughed to a depth of from one-half to three-quarters of an inch, and a quarter to half an inch wide for the reception of the glass, according to its thickness, not differing in any respect from ordinary lights in the formation of the rebate; the only divergence from ordinary glazing is that no putty above the glass is used. The glass is to have a bed of putty to lie on, and, the square being well pressed down, a copper tack at each bottom corner will prevent the glass slipping down, and two above the glass a little higher than the bottom of the square will prevent it being blown out. The next square is then introduced with not more than half an inch of lap on the square below, and a tack on each side so as to receive the edge of the glass will prevent the square slipping down, and at the same time secure the upper part of the square below from being lifted. Tacks above the square as in the

lower one at about an inch from the bottom will secure it in position, and so on to the top of the sash. In pressing the glass down some putty will be squeezed above the level of the glass; this should be dressed off level with it and give the rebate above the glass a coat of paint so as to reach on to the glass, but not more than the width of rebate, the sharp edges of the upper part of which having previously been planed off; but this is not material. The roof will be perfectly watertight, and repairs are much more readily effected than with putty above the glass.

The advantages of the system are—not a quarter of the putty as in the old system is necessary, and as there is none on the outside to part from the wood or glass and let in the wet, whilst repairs are done in less than a quarter of the time, all that is necessary being to draw the tacks with the pincers, remove the bottom putty, renew it, and put in the new pane. As to its interfering with painting, there is the same rest for a ladder as with putty above the glass, and there is only woodwork to paint. The tacks may be three-quarter-inch tinned, or preferably copper, and are best with small heads, but sprigs answer very well. This mode of glazing is cheaper, easier, and every way better than with putty in any form above the glass.—G. ABBEY.

#### AN INTERNATIONAL ROSE ELECTION.

IN November, 1879, we published a list of questions from the President of the Agricultural and Horticultural Society of Wittstock, Germany (Frederich Schneider), to which he solicited replies with the object of reducing the four or five thousand Roses grown in gardens to a limited number of really valuable varieties that may be specially recommended for cultivation. To those questions 72 replies were submitted by horticultural societies, 155 by nurserymen, and 135 by amateurs in Germany, France, England, Belgium, Italy, America, &c. In the preface to the results of this election Herr Schneider states this is the only list in existence where the age of the varieties and the raisers' names are attached—an error that needs correction, as the plan has been adopted in several elections that have appeared in our columns. In the election in question a great number of Roses are named, but we only publish the number requested under each section.

##### RESULTS OF THE POLL.

Which are three most perfect Roses as regards construction and form, substance, shape, habit, and scent in the following colours?

HYBRID PERPETUAL AND BOURBON ROSES.—*Pure White*.—Boule de Neige, Baronne de Maynard, and Louise Darzens. *Tinted White, Blush, and Flesh Colour*.—Souvenir de la Malmaison Capitaine Christy, and Elisa Boëlle. *Pale Pink and Light Rose*.—La France, Madame la Baronne Adolphe de Rothschild, and Madame Marie Finger. *Bright Pink and Deep Rose*.—Paul Neyron, Victor Verdier, and John Hopper. *Carmine*.—Marie Baumann, Madame Victor Verdier, and Alfred Colomb. *Scarlet and Vermilion*.—Fisher Holmes, Souvenir de Spa, Duke of Wellington, and Sir Garnet Wolseley. *Purple and Crimson*.—Louis Van Houtte, Sénateur Vaisse (Fran. Fontaine), and Eugène Appert. *Dark Crimson, Brownish, and Blackish Maroon*.—Prince Camille de Rohan, Souvenir de William Wood, and Empereur de Maroc. *Violet*.—Pierre Notting, Reine des Violettes, and Gloire de Ducher. *Striped*.—Panachée d'Orleans, Panachée de Luxembourg, Perle des Panachées (Village Maid).

TEAS AND NOISETTES.—*Pure White or Slightly Tinted*.—Aimé Vibert, Marie Guillot, and Sombreuil. *Blush and Pink, Rose*.—Souvenir d'un Ami (Queen Victoria), Adam (President), and Madame de Vetry. *Tinted Pink and Rose*.—Homère, Madame Céline Noirey, and Madame Bérard. *Pale and Bright Yellow*.—Maréchal Niel, Perle de Lyon, and Perle des Jardins. *Yellow Tinted*.—Gloire de Dijon, Belle Lyonnaise, and Adrienne Christophle.

WHICH ARE THE THREE MOST BEAUTIFUL MOSS ROSES?—Souper et Notting, Cristata, and Rosa centifolia muscosa.

WHICH FIVE VARIETIES OF ROSES ARE THE GREATEST FAVOURITES AND THE MOST GENERALLY CULTIVATED IN THE DISTRICT OF THE CORRESPONDENT?—Gloire de Dijon, Souvenir de la Malmaison, Général Jacqueminot, La France, and Maréchal Niel.

WHICH FIVE ROSES DISTINGUISH THEMSELVES ESPECIALLY BY THEIR UNINTERRUPTED BLOOMING?—Gloire de Dijon, La France, Souvenir de la Malmaison, La Reine de l'Île-Bourbon, and Madame Alfred de Rougemont. *Through Superior Scent*.—Maréchal Niel, La France, Gloire de Dijon, Rosa centifolia, Pierre Notting. *Through their Hardiness and Insensibility Against Frost*.—Général Jacqueminot, Jules Margottin, Triomphe de l'Exposition, Rose de la Reine (Reine du Midi), and Baronne Prevost.

WHICH FIVE HYBRID PERPETUALS ARE THE FREEST AND MOST ABUNDANT BLOOMERS FOR THE SUMMER?—La France, Jules Margottin, Louise Odier (Madame de Stella), Souvenir de la Malmaison, and Général Jacqueminot. *The Freest and Most Abundant Bloomers for the Autumn*?—La France, Aimé Vibert, Gloire de Dijon, Général Jacqueminot, Prince Camille de Rohan, Pierre Notting, and Victor Verdier.

WHICH ARE THE TEN BEST ROSES FOR FORCING?—Jules Mar-

gottin, Louise Odier (Madame de Stella), Triomphe de l'Exposition, Rose de la Reine (Reine du Midi), Mistress Bosanquet, Hermosa (Madame Neumann Melanie Lemarié), Gloire de Dijon, Souvenir de la Malmaison, John Hopper, and La France.

WHICH FIVE VARIETIES ARE BEST ADAPTED FOR CULTIVATION IN THE ROOM?—Hermosa (Madame Neumann, Melanie Lemarié), Gloire de Dijon, Mistress Bosanquet, Cramoisi supérieur, and Grossherzogin Mathilde.

WHICH ARE THE THREE MOST BEAUTIFUL PILLAR ROSES?—Queen of the Prairies, Baltimore Belle, Gloire de Dijon, and Climbing Jules Margottin.

Which Ten Novelties from 1873 to 1878 are of such Remarkable Beauty that their Cultivation and Distribution can be Recommended without the Slightest Hesitation?—Capitaine Christy, Madame Marie Finger, Perle de Lyon, Abel Carrière, Eugène Fürst, Jean Liabaud, Perle des Jardins, Duchesse de Vallombrosa, Star of Waltham, and Madame Lambard.

### ADIE'S LAWN EDGE-CLIPPER.

VARIOUS implements have been devised from time to time for reducing the labour involved in the tedious process of clipping the grass edges of lawns and verges, but none of them that we have tried approaches in practical utility the one we now submit to our readers.

The machine may be described as a pair of self-acting edging shears of the old construction adapted to the new style of operating. A cylindrical roller having an axle working in a journal attached to the tang of the lower blade runs on the grass, and, by

Fig. 32.—Adie's Lawn Edge-Clipper.

means of a three-armed cam attached to the other end of its axle, lifts the top blade of the shears by pressing on a tooth attached to its tang end, and as the cam passes the tooth the top blade is shut with a slam by means of a spring, cutting the grass instantaneously, and clearing the way for the forward run of the machine preparatory to the next cut. As the rate of cutting is regulated by the rate of propulsion any speed may be attained, ten times faster than by the old shears being easily obtainable. In use it needs a pressure of 2 or 3 lbs. downwards, the under blade being held with its point from a quarter to half an inch under the turf edge, and the back of the blade itself pressed on the earth edging, the cut being thus close, and the edge smoothed by the blade passing along it.

Mr. Adie, amongst a large number of scientific and other patents (twenty to twenty-five), was the fortunate inventor of the very popular horse clipper, now reaching over the million manufactured in fourteen years, and to which invention, like so many English patentees, he only established his right by a double suit in the House of Lords.

This edge-clipper we have tried, and know not which to admire most—its simplicity or efficiency. It is as great an advance on the old shears as the lawn mower was over the scythe, and we suspect will eventually find its way into all pleasure grounds and gardens where lawns are more or less extensive. The roller is 5 inches in diameter and 4 inches wide, the blades of the shears being 6 inches long. The shaft is about 4 feet in length.

FUTURE OF GARDENING.—“WILTSHIRE RECTOR'S” remarks on “The Future of Gardening” were interesting to horticulturists, as has been proved from the number of contributions that have

since appeared relating to the subject. I am confident there is a great future for gardening. Many of your readers have condemned farmers for vegetable growing, stating that the supply exceeds the demand; that may be so, especially in mild winters. A far more promising crop is fruit, of which there is very rarely an overabundance. I think farmers could probably grow a great many varieties of fruit trees. Cornish growers very rarely have a superabundance of vegetables or fruit.—W. ROBERTS, *Penzance*.

### STRAWBERRY FARMING.

(Continued from page 106.)

Cultivation.—I may again remark that the methods of cultivation I describe are not those generally practised among the growers in this quarter, where there is certainly much careless work. Whole fields may be seen where the plants have had all due attention for one season, but thereafter have been neglected, the consequence being that the native weeds and grasses have so usurped the soil that they have annually to be mown down with the scythe. I describe only those methods that are followed by the most successful cultivators.

As soon as the young plants are fairly rooted and begin to grow the surface should be lightly stirred with the hoe, and this should be repeated during the season as often as weeds are observed. Thorough attention to cleanliness during the first season will save much trouble the following years. When runners begin to appear, or at least before they are rooted, they should all be cut off. Children do this very quickly with sharp knives or scissors. This process may have to be repeated at intervals during the season. The resources of the plants are thus concentrated, and their vigour enables them to form strong fruit buds in anticipation of next season's fruit. At the time the first runners are cut all fruit blooms of spring-set plants should also be removed, as it is better to forego the chance of a meagre and uncertain return the first year to ensure a bountiful crop the second. After the last hoeing for the season and just as winter is approaching the matter of mulching is to be considered. We recommend it in all cases as a protection against that alternate freezing and thawing, so detrimental to plants in the longer days at the beginning and end of winter. Whether it is necessary also for the purpose of further enriching the soil will depend on the liberality with which it was treated before setting the plants. Generally, however, we consider that as the young plants have not yet to any great extent exhausted the manure applied at planting, some mulch of less manurial value may be applied for the first winter. Spent bark, fibre refuse, or decayed leaves may be employed, being sprinkled to the depth of an inch or so along the crowns of the plants; or if none of these is available a little of the soil may be drawn over them at the last hoeing. For succeeding years, however, nothing is so good as a compost of the decayed remains of the previous season's weeds, turf, &c., that has been reduced by mixing with lime and afterwards mixed half and half with fresh stable manure allowed to heat thoroughly in order to kill all seeds, and turned several times in course of the autumn. This compost should be carted along the rows and spread directly from the cart. The drill-harrow or grubber should afterwards be run between the rows to slacken the soil and leave all neat for winter.

After the danger from heavy frosts is over in early spring the hoe should be again at work, care being taken to remove the mulch that may lie directly on the crowns of the plants. Unless weeds are very persistent no more care should be required until the appearance of the new runners, which should be cut as before. The more faithfully this is attended to the greater will be the crop, for it so happens that the runners and fruitstems are thrown out about the same time, and the unchecked growth of the former is much against the setting of a large crop of fruit.

By this time the grower ought to have his mind made up as to how he proposes to market the crop. If it is intended for table use provision must be made for keeping the fruit clean; but if for preserving factories no special attention to this is required, as the berries can be washed, and are not objected to on this account. I usually lay rye straw between the rows and close to the plants, and though this is rather expensive—viz., from 50s. to 60s. per acre, I consider it a profitable investment. In wet weather it keeps the fruit clean and is comfortable for the gatherers; and in dry weather it preserves the soil cool and moist, keeps down weeds, is of some manurial value, and after being raked off in autumn is still of use in the stable or piggery. Where straw is not obtainable forest leaves, spent tan, or fibre refuse may do equally well, though I have not tried these.

Reserving remarks on gathering and marketing the fruit for a future paper, as also on the question of artificial manures, and special measures for protection against the enemies of the Straw-

berry, I shall resume the routine of work for the rest of the season. As soon as the fruit is gathered the runners that may meanwhile have been thrown out should all be cut. This is most satisfactorily done among old plants by means of a common reaping hook or sickle-shaped knife set in a handle about 2 feet long. Many use a revolving cutter made from an old circular saw and fastened to the side of a light plough, but this is not a satisfactory system; it only cuts those runners that are not in the line of the plants, and, especially in stony ground, soon becomes so blunted that it rather tears than cuts, and consequently tends to disturb the old plants. All loose straw, runners, and weeds should now be carted off and a more thorough cleaning commenced. As the ground is now trodden hard from traffic in gathering, &c., it must be thoroughly loosened between the rows either by hand labour with the digging fork or by means of the paring plough or grubber passed both ways. In the former case though more expensive, the whole work may be finished at one operation, the weeds from several rows being thrown together into one and wheeled off as they accumulate. In the latter case the common hoe, or better still the American steel-toothed hoe, must be used to finish the work. The soil should be gradually worked towards rather than away from the plants, so as to give the new roots now forming a better chance. A fresh mulch and a final turn of the harrow finishes the work for the season. In succeeding years the routine of work should be similar to that just described. The winter season may be profitably occupied in collecting material suitable for compost, such as turf, road scrapings, leaves, runners, &c., to be reduced by means of lime and worked up with manure as before described. Where clearing has been neglected in autumn it is better left till spring. In conclusion I may add that all experience in this quarter favours deep cultivation. I have just opened a gravel pit in a plot of Elton Pine plants, and find a mass of the root fibres round its sides that have penetrated to the depth of from 24 to 27 inches, half of that into the gravel; and as these roots seem to have taken a nearly perpendicular direction, there is far less risk of damaging them by deep digging between the rows than is generally imagined.—WILLIAM RAITT, *Blairgowrie*.

## NOTES AND GLEANINGS.

JUST on the eve of going to press we have received two small but excellent works on gardening—"CARTERS' PRACTICAL GARDENER," and "ROSES IN POTS," by Mr. William Paul, both of which demand fuller reference than we can give now. Mr. Paul's book is the fifth edition of a work that all cultivators of Roses in pots should possess. Messrs. Carters' issue is an entirely new work, new both as regards writers and many of the subjects. We can only say at present that it far surpasses all former editions in appearance, size, and quality, and that all those who purchased the old work and were satisfied with it may safely purchase the new; while those gardeners and amateurs who do not possess "Carters' Practical Gardener" need not hesitate to add it to their libraries, for its subjects are varied and its teachings reliable.

— WE learn that the specimen of *PRITCHARDIA GRANDIS* referred to last week is not the only one in this country, as Messrs. Veitch have young plants, and others are included in some English botanic gardens. It appears a case of young plants was sent to England a short time since, from which the stock has been derived. There is thus a probability of this handsome Palm coming into cultivation, though the number of plants must necessarily be extremely limited at present.

— AS will have been seen by an advertisement in our last issue, Mr. W. Iggulden has prepared a *MANUAL ON THE TOMATO*, giving cultural directions for maintaining a continuous supply of fruit. The work contains chapters on early, successional, and late crops; culture in frames and in the open air; growing the fruit for exhibition and market purposes; with instructions for amateurs, an estimate of varieties, and a list of

uses to which Tomatoes may be applied. The work is thus comprehensive; while the information, being a record of the practice of one of the most successful Tomato cultivators of the day, is thoroughly sound. The author has evidently endeavoured to "tell all he knows" on the subject, even at the risk of approaching prolixity. All who are desirous of having sound information on Tomato culture in a space of seventy pages cannot do better than obtain this Manual; and if they adopt intelligently the practice detailed they will achieve success in the culture of a fruit which is so rapidly rising in public estimation.

— THE "Journal of Applied Science" has the following note upon FRUIT TREES IN BOHEMIA—"According to recently published statistics the number of fruit trees in Bohemia of all sorts, but chiefly Apples, appears to be 14,000,000. Of these 10,000,000 are in gardens, 1,600,000 in waste lands, and about 2,000,000 on the sides of the public roads. The number of young trees annually planted is about 1,500,000. Between 6,000 and 7,000 miles of road are planted with fruit trees, mostly of the best sorts, and the revenue therefrom is very large. The fruit is largely exported to the north of Germany and Russia."

— THE members of the LIVERPOOL HORTICULTURAL ASSOCIATION are to be congratulated on the condition of a Society which, although only two years old, appears to be established on a substantial basis. With such distinguished patrons as the Earls of Derby, Sefton, and Dalhousie, with the Mayor as President and an influential list of Vice-Presidents, with nearly three hundred honorary members and a still greater number of ordinary members, including nearly all the gardeners of the district, with a practical working Committee, the prospects of the Society are bright, and with unity of effort and the support that an excellent organisation demands the objects sought will be attained. These are, as stated in the report, to promote public interest in, and the practice of scientific horticulture in Liverpool and the district, and afford the members opportunities of becoming mutually acquainted, and of profiting by each other's knowledge and experience by the reading of papers on the subjects which interest them, and holding exhibitions to enable them to compare the results of their knowledge and skill with those of the members of other societies and of gardeners from other districts. The income of the Society last year was £1118 16s. 3d.; and although, in consequence of inclement weather, a loss of nearly £80 was incurred at the autumn show, yet there is a balance of income in favour of the Society of £234 8s. 10d., which is a considerable increase on that of the previous year, and indicates judicious management on the part of the officials.

— A PARAGRAPH was sent to us last week which we published on page 132, directing attention to Mr. Shirley Hibberd's *SYNOPTICAL LIST OF VARIETIES OF POTATOES*. The list, which is the result of "severe selection" includes 313 varieties. Such a list will perplex at least as much as it will aid the majority of Potato cultivators, and our friend may well have another "melting down" day, for it is conceivable that not half the above number of varieties are needed either by growers of Potatoes for exhibition or culinary purposes. Short classified lists of Potatoes in the different sections would be useful, and especially so would an accurate list of synonyms. We think a "severely selected" list should only include varieties of merit, yet the first named in the selection in question (*Acme*) is described as a "coarse and worthless American variety," and several others are referred to in similar terms. No doubt this is useful information, but why include such varieties at all? We hope Mr. Hibberd will pursue the subject of selection and elimination further, for we agree with him that "it is surely time we had some good Potatoes," and we shall arrive at this desideratum the sooner by excluding all the bad ones. The Potato exhibitions have done much good

in promoting superior culture, but they have also stimulated the production of varieties of no practical use. If a new Grape, Pear, Melon, or Cucumber is not fit to eat it is not worthy of culture, however good the appearance may be, and the same rule we presume should apply to Potatoes.

— WE have received a schedule of the MANCHESTER NATIONAL SUMMER EXHIBITION, which is announced to be held from the 3rd to the 10th of June of the present year. Fifty-one classes are enumerated in two sections, thirty-two being devoted to amateurs and nineteen to nurserymen. Liberal prizes are offered for fruit, flowers, and plants, Orchids being particularly well provided for, as no less than eight classes are devoted to them. One special class is noteworthy; Henry Shaw, Esq., of Buxton, offers the first two prizes, value £10 and £5, and the Society gives the third prize of £3 for six specimen Orchids—single plants—"made up" specimens being excluded.

— RELATIVE to exhibiting plants at the meetings of the ROYAL HORTICULTURAL SOCIETY, South Kensington, the Rev. George Henslow requests us to publish the following letter that he has sent to many nurserymen and exhibitors:—

"I have noticed that certain plants—the particular merits of which may not be always apparent at first sight—are not unfrequently exhibited at South Kensington and brought before the Floral Committee, the members of which consequently feel some difficulty in judging of their merits for want of fuller information about them than can be obtained by mere inspection at the table. It has occurred to me that it might be an assistance to both exhibitor and the Committee if you would communicate to me in writing, a day or two before the Exhibition, such details of any particular plants as you may desire to be specially brought to the notice of the Floral Committee. I should be most happy, in my capacity as 'Demonstrator,' to describe such particulars to the members as you might furnish me with. By adopting this plan I think the Committee would be better able to judge of the merits of any such plants. I also wish to say that if you should happen to meet with any herb, shrub, or tree which exhibits remarkable growths, diseases, sports, &c., or, in fact, anything whatever that may strike you as peculiar, I shall be extremely obliged if you would kindly forward the same, addressed to me as 'Secretary of the Scientific Committee, care of Mr. J. D. Dick,' with the addition of any notes or observations which you may think fit to make. I shall have great pleasure in bringing the same before the notice of the Scientific Committee."

It would certainly be of great advantage if a request so reasonable were, as far as possible, complied with by all exhibitors.

— WE understand that our correspondent Mr. A. Pettigrew has disposed of the PRIORY VINEYARD, Sale, Cheshire, to Messrs. F. W. & H. Stansfield of Pontefract. Mr. Pettigrew intends residing in Scotland for a short time with the object of recruiting his health, and he proposes taking his bees with him.

— MR. PETER HENDERSON, writing in the "American Gardener's Monthly," has the following remarks upon ENGLISH HORTICULTURISTS:—"It has been stated that one reason why vegetables sell higher in London than in New York is that rents are higher, and quotes £7 (35 dollars) per acre as being paid for gardens supplying the London market. The price paid as rent per acre for the gardens that grow for New York markets will, I think, average higher. In Hudson Co., N. J., the average is probably 40 dollars per acre. Some of them nearest the city pay twice that, and that, too, in quite a number of cases only from year to year, as the grounds are held as too valuable to give a lease; and yet not a few of them have made good-sized fortunes, even when selling in a market averaging 25 per cent. less than that of London, while the price paid for labour was 50 per cent. more. By far the most successful market gardeners in this vicinity are Englishmen; but Englishmen whose necessities on coming here forced them to adopt common sense methods; Englishmen who were shrewd enough to take a better idea than that they had previously had from any man, whether black or white; Englishmen who were far too sensible to let their conceit stand in the way of their interests. Englishmen, also, in the vicinity of New York in the flower department of horticulture have reason to be proud of their eminence. A majority of those managing the roseries at Madison, N. J., where Roses are perhaps better handled than in any part of this country or Europe, are

Englishmen. The proprietors of the best collection of plants for commercial purposes are all Englishmen. Our largest grower of winter flowers is an Englishman—one who a few years ago, on his return from a European trip, was so impressed with the slow methods in use there, that he said that, had he been a younger man, he would want no better field for business than London after his ten years of American experience."

— Two interesting papers on THE COFFEE LEAF DISEASE were read at the meeting of the Linnean Society on the 3rd inst., the one treating of its ravages in India, the other its nature and spread in South America. In the first Mr. Wm. Bidie, in a letter to Mr. J. Cameron of Bangalore, refers to the Coorg country, situated in the Western Ghats, where European enterprise in Coffee has been wholly developed within the last twenty-five years, and no disease was observed till four or five years ago. The author mentions that the disease appears to have been imported from Ceylon by way of Chickmoorloor, a district of Mysore, sixty miles distant from Coorg. It seems worst in impoverished exposed fields, and least where there is shade and rich soil. A small red insect has been noticed feeding over leaves covered with the pest, but what the insect's relation is to the disease as yet remains undetermined. Plants grown from Ceylon seed suffer most, while those trees of Coorg origin and growth are least affected. A system of "renovation-pitting" has been successfully tried, a pit being dug at short intervals wherein, after judicious pruning, all the affected leaves are buried, and this precaution seems to check the spread of the disease, particularly among the Coorg Coffee trees. In the second communication Dr. M. C. Cooke describes and summarises all the data extant up to the present time of the progress of Coffee disease in South America. Plantations in Venezuela, Costa Rica, Bogota, Caracas, and Jamaica have been affected. He discourses on the nature of the blight, and is of opinion that the disease is a complicated one, being himself as yet unprepared to affirm that either the Septoria, the Sphaerella, or the Stilbum, three so-called different kinds of fungi, or all together, is the true cause of the disease. At the same time he thinks it possible that none of these forms of fungus are autonomous, and that all may be related to each other as forms or conditions of the same fungus, of which Sphaerella is the highest and most perfect manifestation.—(*Nature*.)

— MR. J. S. WOODWARD recommends in the *New York Tribune* the following wash as a sure preventive of SHEEP BARKING FRUIT TREES. Take soap, the dirtier and stronger the better, and make a very strong suds; dissolve one-fourth pound whale-oil soap in every six gallons, and into this stir sheep manure until it is as thick as good whitewash, with a brush or old stub of broom, and with this mixture wash the trees as high as the sheep can reach, and no sheep will come near enough to rub against them for at least two months, the time depending upon the amount of rain. We keep the mixture handy and repeat the application as often as necessary, usually not more than twice in a summer. Sheep running among fruit trees should have plenty of good fresh water; it is thirst that first induces them to gnaw the bark, but after they have once got a taste they eat because they like the bark. The above mixture will effectually keep them away, and besides is a very good application for the health of the trees, keeping the bark smooth and fine, and killing any insects that it comes in contact with.

#### PARAFFIN TUBS.

As I have seen these recommended for large plants that have outgrown their pot room, could any of your numerous readers that have used such inform me what operation the tubs have gone through preparatory to using them? as I apprehend that, if used as bought, the oil in the wood would kill the young roots of such plants as Tree Ferns and Palms. Would a thorough scalding with

boiling water so cleanse them as to render them fit for use? The subject may be of a little importance to some gardeners, as these tubs may often be bought cheaply, and one of them if sawn in halves would do for two plants.

Whilst writing about tubs I may state that spirit tubs, at all events those that have contained rum, are very destructive to the roots without previous scalding with boiling water. Some twelve years ago, when under gardener, I was directed by my employer to put a fine young plant of *Cyathea princeps* into a small tub about 2 feet in diameter, and about the same in depth. The tub had contained rum, and was not scalded before using it; the consequence was that when the roots reached the sides the young pinnules on the fronds drooped and turned brown, the older ones soon assumed the same appearance, and the plant appeared to be dying. It was placed on the ground, and two men with a four-tined steel fork each raised it bodily out, it was then found that the extremities of the roots that had reached the sides of the tub were all dead. The tub was then well scalded, some of the soil was picked away carefully from the ball to enable the plant to be returned to its former position and then filled up. It soon recovered and never showed the same symptoms as before, but grew rapidly in a shaded stove, and made a fine specimen. This *Cyathea* is one of the most handsome Tree Ferns, and is especially suitable for a large house.

I have a large paraffin tub that has been in use four or five years. It has had boiling water in it a great many times, and has often been used for washing flower pots, but even now after four or five years of such use, small quantities of oil may be occasionally seen floating on the water.—A. HARDING.

#### ANGRÆCUMS.

A WIDE range of floral variation is one of the striking characteristics of the great Orchid family, and yet many of the genera are clearly marked and easily distinguished even by non-botanical observers. Some genera, however, contain species differing very greatly among themselves in the form and colour of the perianth, though in other structural characters they are closely allied. Among the first-named the *Angræcums* may be included, for they bear a strong family likeness in general appearance and colour, yet with sufficient diversity in the size of the flowers and in the form of the inflorescence to render them all more or less attractive. With the exception of a few species they cannot, however, be ranked among the really useful Orchids which everyone may grow—not from any great difficulties attending their culture, or from deficiency of interest, but because where the object is to provide a brilliant display in the Orchid house there are many others better suited for the purpose easily procurable, and requiring less heat than the majority of species constituting the genus under consideration. A marked uniformity of colour prevails in the *Angræcums*; from pure white to creamy yellow is the extreme range of tints, and the charming elegance of some species with delicate flowers, long slender spurs, and gracefully arching racemes, or the stateliness of the strong-growing forms with large flowers, can scarcely compensate for what appears to some as a defect. Possibly this is the reason we seldom find a good collection of the species in one garden, though a large number of forms are included in the genus, and many have been introduced to cultivation. In some of the largest collections there is not a dozen species, though the nurserymen of this country offer about twenty, and probably nearly thirty are now represented, some being extremely rare. It is seldom, however, that a collection of Orchids, even of moderate size, is without at least one or two representatives of the genus, and many more might be advantageously grown wherever there is sufficient accommodation for them.

The genus *Angræcum* was established in 1822 by Aubert du Petit Thouars, to include certain species of epiphytal Orchids found in East and West Tropical Africa, Madagascar, and the adjacent islands, and in a work published by that botanist several of the species now in cultivation were described. It was then believed that the geographical range of the genus was very limited, but species have since been found in Japan and the West Indies. Their headquarters are Western Tropical Africa, from Sierra Leone to the River Gaboon, the opposite side of the great continent about Zanzibar, in Madagascar, the Comoro Islands, Bourbon, and Mauritius. They are essentially heat and moisture-loving Orchids, and with the exception of the Japanese *Angræcum falcatum* they need the warmest compartment of the structure devoted to such plants. Being epiphytal in habit the majority require to be grown in baskets or on blocks of wood; but those of vigorous habit, such as *A. eburneum* and *A. sesquipedale*, are usually grown in pots with abundance of potsherds as

drainage, 'good fibrous peat and sphagnum, or the latter alone, that moss [also being employed when the small forms are grown in baskets or on blocks. As with all Orchids of similar habit and from similar climates, abundance of water is required during growth, and a less amount when at rest; in other respects they may be treated like most of their allies. A few descriptive notes upon the best of the species may be of interest, and will serve to indicate the chief characteristics of the genus.

*A. sesquipedale*.—One of the most remarkable Orchids known, and having the largest flowers in the order, it is also unquestionably the most handsome in its genus. Such qualities entitle it to some consideration, and several points in its history are also invested with peculiar interest. It is, perhaps, the best known of the *Angræcums*, for it is found in the majority of moderately large collections of Orchids; and very deservedly is it so popular, for the vigorous habit of the plant, the dark green distichous leaves, and the great ivory white flowers render it worthy the attention of all growers. In the ordinary type of the species the flowers are about 6 to 8 inches in diameter, the spreading sepals and petals imparting a star-like appearance to them, and the spurs are from 10 inches to 1 foot in length. Messrs. Veitch have a grand variety, which is, I believe, named *superbum*. It is greatly superior to the ordinary form both in the size of the flowers and the purity of the white. In both the flowers are borne on a moderately short peduncle, and are arranged in a racemose manner but widely spreading. They are produced during the winter months, and last in good condition for several weeks, the sweet Lily-like fragrance which the blooms possess rendering them additionally attractive, and a single specimen upon the stages of an Orchid house will fill the whole structure with perfume.

This species was one of those known to Du Petit Thouars in 1822, but it was about thirty-four years later when living plants were first brought to England by the Rev. W. Ellis, who found it in 1854 growing on the branches of trees on the margins of forests in the low and hot districts of Madagascar. A few years later a plant produced flowers at that traveller's residence, Hoddesden, when the plant attracted much attention owing to the peculiarity of its structure. Since that time it has been generally distributed; and on December the 10th, 1861, Messrs. Veitch & Sons exhibited a specimen at a meeting of the Royal Horticultural Society, when a first-class certificate was awarded for it. As regards the structure of this Orchid the chief peculiarity is the extremely long spur, which, though rarely exceeding a foot in length in cultivation, is said to attain 1½ foot in its native habitats, and from that character the specific name is derived. This unusual length is supposed to be an adaptation in connection with the fertilisation, and in Mr. C. Darwin's work on Orchids he lucidly described the mode by which this can be accomplished. He considered from an elaborate examination of the structure that only large insects with probosces long enough to reach to the bottom of the spur where the nectar is secreted could effect the fertilisation, and he thence concluded that some kind of insect, probably moths, existed with probosces large enough for the purpose, though at that time one was not known to possess the organ of such a size. A species of *Sphinx* has been subsequently found in Brazil with a proboscis nearly a foot long, so that the probability of similar species existing in Madagascar is increased, but I am not aware that one has yet been found there. Mr. Darwin's observations have thus received a partial confirmation, and no doubt will at some time be proved to be quite correct.

*A. eburneum*.—This is another of the strong-growing species, but not so remarkable as the one just described, though from its free-flowering habit it is one of useful *Angræcums*, especially as the flowers are produced at a time when the Orchid house is comparatively dull—namely, from December to February. Grown in pots as already mentioned excellent results are obtained, and during the last few months several unusually fine specimens in some of the chief London nurseries, Kew, and elsewhere have been noted in the Journal. The plant is of robust habit with long leaves arranged in a similar manner to those of *A. sesquipedale*, and it bears numerous erect spikes or racemes of large flowers, of which the roundish pure white lip forms the most conspicuous portion, the sepals and petals being narrow and of a greenish tint. Two varieties are known—one named *virens*, which has smaller and less handsome flowers than the species, but is rather more graceful in habit. Another, named *superbum*, is decidedly superior to the type in the size of the flowers, and is said to be one of the introductions of the Rev. W. Ellis. Of this variety a remarkably handsome specimen was grown a few years ago at Farnham Castle by Mr. Lawrence, and I recently noticed a very good example in Mr. B. S. Williams' nursery at Holloway.

The species is native of Madagascar, where it was found by

Mr. Forbes a few years previous to 1830. It was also found in the Isle of Bourbon by another traveller. Specimens were introduced to the Horticultural Society's Gardens, where one flowered in November, 1831, from which a figure was prepared for the "Botanical Register," where it is stated that it was believed the

specimen was the only one in the country. Twenty years later a much better figure was published in the "Botanical Magazine," prepared from a plant at Kew which had been received from Mr. Clowes.

*A. citratum*.—This is very distinct in habit from *A. sesquipedale*

Fig. 33.—ANGRÆCUM CITRATUM.

and *A. eburneum*, but in gracefulness and beauty it is scarcely surpassed in the genus. The accompanying engraving admirably represents a plant growing in Messrs. J. Veitch & Sons' nursery, Chelsea, and proves how well the small Angraecums, like most other epiphytal Orchids, thrive in the small shallow pots so successfully employed in that establishment. The plant flowers freely, producing elegant pendulous racemes frequently a foot in length, with closely packed small creamy white or pale yellow flowers, which are nearly an inch in diameter, with spurs about  $1\frac{1}{2}$  inch long. The colour is very delicate, and it is to that the term "*citratum*" refers, and not to the possession of any marked fragrance as some have supposed. It is a charming little Orchid, and when suspended from the roof of an Orchid house its arching racemes are seen to the best advantage in contrast with the deep green foliage of the plant, and the rich colour of some *Dendrobies*, the glowing little *Sophranitis*, and the showy *Ada aurantiaca*, most of which were noticeable near the species figured, the two former succeeding equally well in the small pans or pots mentioned.

Though *A. citratum* has not been many years in cultivation it was known to Du Petit Thouars, who described it in the work already referred to. It is a native of Madagascar, whence Messrs. Veitch obtained it nearly twenty years ago, and in their nursery it first flowered in March, 1865. In the following year a specimen was exhibited at Kensington by the same firm in a class for new Orchids shown in flower for the first time, when a prize was awarded for it. In 1867 a very good coloured engraving of it appeared in the "Botanical Magazine," and on February the 18th, 1874, the Floral Committee of the Royal Horticultural Society

awarded Messrs. Veitch a first-class certificate for the plant. It unquestionably merits a place wherever elegant Orchids are appreciated.—L. CASTLE.

(To be continued.)

**DIMORPHIC FLOWERS IN HOUSTONIA.**—In an extract from the Proceedings of the Academy of Natural Sciences of Philadelphia Mr. Thomas Meehan has these remarks — "Flowers dimorphic in their sexual character are well known.

Generally there is little difference in the corolla between the short-styled and long-styled flowers, but in *Houstonia cærulea* the long-styled form is accompanied by a thick tube, while the tube in the short-styled form is not more than half the diameter of the other. In this species of *Houstonia* the anthers are placed on a ledge which is at the base of the tube in the long-styled form. In the short-styled form the anthers are brought to the mouth of the corolla without any lengthening of filaments, but by the bringing-up of this ledge on which the anthers are placed. The position of the anthers at the mouth or at the base of the tube, was in fact decided by the modification of the form of the corolla

tube. In a recent examination of *Houstonia serpyllifolia* on the top of Roan Mountain in North Carolina, precisely the same characters were found. On the same mountain *Houstonia purpurea* abounds, and also has a similar sexual dimorphism, but in this case the elevation of the anthers is due to the lengthening of the stamens, and the form of the corolla tube is the same in both sexual forms. The number of plants representing each sexual form is about equal. Both forms seemed to be equally fertile. In regard to cross-fertilisation the long-styled would be in the best position for receiving pollen from foreign flowers, but the short-styled one would more readily receive its own. As cross and self-fertilisation had an equal advantage he would infer that the dimorphism had little reference to fertilisation as a final cause."

#### HARDY FRUIT GARDEN.

For standard Apple and Pear trees that have attained sufficient size and age to bear fruit, but fail to do so, the present is a good time to head them down preparatory to grafting with other and approved varieties. Some kinds of Apples and Pears, particularly the latter, are liable to afford fruit of inferior quality, or the trees to be subject to disease in some localities, whilst in others they are satisfactory both in quantity and quality of the fruit. Scions of the required variety may now be taken, and the ends placed in the ground in a shaded situation to retard the action of the sap until it is well up in the stocks. Select vigorous well-ripened shoots of last year's growth for scions. Recently planted standard and other trees should be securely staked, and be well mulched with partially decayed stable manure. Bush fruits are now in that condition as regards the buds, particularly Gooseberries; and bullfinches must be watched for, or a pair will soon do a great amount of injury. Where shooting them is objected to the bushes may be dressed with diluted Fir tree oil or nicotine soap, which must be repeated after heavy rains. Pruning and nailing-in Morello Cherries and other trees on north walls must be attended to, cutting out any shoots devoid of bearing wood, so that last year's shoots can be trained in their full length. Cherries, Plums, Peaches, and Nectarines, being subject to the attacks of aphides, &c., should be dressed with an insecticide. We find nothing better than a mixture of 1 lb. soft soap to a gallon of water, half a gallon of tobacco juice, half a gill of spirits of turpentine, and a little sulphur to thicken it. It should be applied with a brush, and is equally efficacious against scale on Pear and Apple trees, also for American blight, in which case omit the sulphur.

#### FRUIT HOUSES.

*Cherry House.*—The flowers will now be rapidly expanding. Continue ventilating at 50°, and do not exceed 55° by artificial means in the daytime, and 40° to 45° at night. Cease syringing the trees, and maintain a genial atmosphere by damping. Artificial impregnation must be attended to on bright sunny days. See that there is no deficiency of moisture in the borders, and if necessary afford a liberal supply of water at a temperature of 65°. Trees in pots will require water more frequently, and must not be neglected in that respect. Although it is not advisable to fumigate when the trees are in blossom, it must, however, be resorted to if aphides appear.

*Peaches and Nectarines.*—Thinning the fruit will also soon require attention where too thickly set, removing the smallest first and all those on the under side of the branches, unless there be not sufficient on the upper side for a crop. Syringe the trees twice a day after the fruit is set, and advance the temperature to 55° at night, 60° to 65° in the daytime, ventilating from 65°, and allowing an advance to 70° or 75° with sun heat and a free circulation of air. Assist weakly trees with liquid manure not lower in temperature than the air of the house, and see that outside borders have the protection of leaves and litter to prevent chill. In the house started at the beginning of the present month the flowers are now showing colour, and the syringings must be discontinued when they expand, damping the house, floors, and borders

twice a day. See that the inside border is not dry, and if necessary supply water at a temperature of 70° to 75°, assisting weakly trees with liquid manure. Where there is a superabundance of flowers draw the hand on the under side of the shoots downwards. If Peach aphides infect the shoots fumigate on two or three consecutive evenings before the flowers expand. When in flower 50° at night and 55° by day artificially, advancing to 65° from sun heat, are suitable temperatures, ventilating freely whenever the weather is favourable, and avoiding a close vitiated atmosphere. Complete the pruning, dressing, and training of the trees in late houses, as well as cleansing the houses, ventilating freely to retard the flowering, unless the demand be continuous, when it may be necessary to start another house at the commencement of next month; in which case the house should now be closed, employing fire heat only to exclude frost. The inside border must be thoroughly moist.

*Strawberries in Pots.*—Batches of plants should be introduced at such intervals as will maintain an uninterrupted succession. The plants started in December have fruit well advanced for ripening, and should be supplied with liquid manure until the fruit changes colour. As soon as indications of ripening are evident the supply of water should be less plentiful, and the atmosphere must be drier to insure flavour in the fruit. Those plants started early in the year are in flower, and should have a somewhat dry atmosphere and as free ventilation as possible. Dust over the blossoms with a camel's hair brush or feather to liberate the pollen, keeping them in a temperature of 55° at night, and 60° to 65° artificially by day, with an advance of 5° to 10° with sun heat. When the fruit is swelling freely secure a temperature of 60° to 65° at night, and 70° to 75° by day, and 80° to 85° from sun heat. Supply liquid manure abundantly. When the fruits are fairly set remove those not likely to swell to a good size, and such as are likely to be deformed. Plants on shelves in Peach houses and vineries will have to conform more or less to the legitimate occupants, but the flowers of the Strawberries should be damped as little as possible, and a little extra ventilation afforded so as to secure a good set. Vicomtesse Hericart de Thury is not succeeding so well in the early crops as last year, but La Grosse Sucrée and Pioneer are fine. Those should be continued introduced to shelves in vineries or Peach houses about to be started, with President, James Veitch, Sir Charles Napier, British Queen, Dr. Hogg, and Cockscomb, the three last being very much superior in flavour to the others, and should be allowed to advance very gradually.

#### FLOWER GARDEN.

Shrubberies are often very much neglected in thinning. Common and Portugal Laurels bear cutting well, and may be formed by judicious pruning into fine pyramid or round-headed bushes, and Yews may be cut into any form desired. The majority of deciduous and evergreen shrubs also stand as much cutting as is necessary to keep them within reasonable limits. The ground amongst shrubs should be only lightly pointed over, and even this is undesirable where quantities of Snowdrops, Crocuses, Scillas, Daffodils, Primroses, Violets, and Anemones are planted amongst them. Dielytras, herbaceous Pæonies, &c., with Lilliums in the more open spaces have a fine effect. All that is necessary is to remove coarse weeds and grasses, and to give a top-dressing of decayed refuse occasionally.

Wistarias, Roses, Clematis, and all climbing plants should be pruned and have the growth re-arranged or regulated, cutting out the weakest and oldest growth, retaining for tying or nailing-in the strongest and best-ripened wood. Roses that make long strong growths, as Cloth of Gold, Climbing Devoniensis, Maréchal Niel, &c., should not be spurred in, but have the old growths well thinned out and the best ripened shoots trained in their full length, except any unripe points, which may be cut away. Proceed with the re-arrangement of herbaceous borders. Phloxes will be starting and should have the shoots well thinned, leaving the strong; but if the plants are old take up, divide, and replant them in well-manured ground. Cuttings of choice kinds now inserted and grown on will afford fine heads of flowers, and are very effective grown in pots for decorative purposes. Delphiniums and Pyrethrums that are growing should be closely watched, as slugs are very fond of them. Give a dusting of quicklime. Ground intended to be planted with Dahlias, Holly-

hocks, Violas, Calceolarias, and other plants requiring rich deep soil, should be prepared by trenching and working in a liberal quantity of manure. Edgings of Cerastium and other hardy plants may now be taken up and relaid.

Pelargoniums should be potted and afforded gentle heat for a short time; they will soon become established and make fine plants. Asters, Ten-week Stocks, Phlox Drummondii, Dwarf Scabions, and other half-hardy annuals may now be sown in pans of light rich soil in gentle heat, keeping them near the glass after the plants appear, ventilating freely on all favourable occasions. Push forward the propagation of bedding plants whenever cuttings are to be obtained. Verbenas and Lobelias when struck should be planted out in pits or frames.

## THE BEE-KEEPER.

### CRUDE HONEY.

NOBODY doubts that there is such a thing as "crude," as distinct from perfect honey, if it be meant that the honey which is sealed up by bees and is stored up for winter use differs greatly in most seasons, and at different times in the same season, from that which they bring in daily and hour by hour from our fields and woods. We do not, therefore, question a great deal that Mr. Pettigrew says upon this subject. We know well all the "facts" that he has advanced. Bees do put honey among the brood at first. They do not always carry it to the store combs at once. The supers do undoubtedly increase in weight by night as well as by day. All this is among the A B C of our knowledge about honey gathering and storing. The answer to Mr. Pettigrew's questions in your last issue is simple enough. Bees, being among the most intelligent of insects, know how to husband their time and arrange their hours of labour so as to utilise to the utmost every available minute that is given them; consequently, as they know the brevity of the honey-producing hours, they wisely give their chief attention to the collecting of it when it is to be had, and as naturally they put it into the cells which happen to be most conveniently at hand and nearest to the one entrance of the hive. Then they rush forth again to collect more, and repeat the operation till the shades of evening or exhaustion of the outdoor supplies gives them liberty to attend to the proper storage of the honey harvest so hurriedly gathered in. Now comes the night-work, which is often as laborious as that by day. The honey is carried drop by drop to the suitable receptacles which have been prepared for it in the store combs of the hive wherever these may be, in supers or elsewhere. We are also perfectly aware that a great change often takes place in the quality of the honey itself—often we say, for the change depends very much upon the varying quality of the honey which is being brought in from the fields. Sometimes, especially in wet or moist seasons, when there is little sun, the honey is thin and watery; at other times, and particularly last summer, it is brought in as "perfect" a sample as the best affords in other years. But, perhaps ordinarily, the change is very considerable which takes place during the time the crude honey is brought in, while it remains in the open cells, and during the time of transfer before it is sealed up.

Where we differ from Mr. Pettigrew is as to his way of accounting for this change. He talks of the bees "converting" the crude syrup into honey, and he asks us to believe that in the process of transfer there takes place a "manufacture of perfect honey;" and by this he means, not a mere change of appearance or improvement in quality, but a radical conversion of one substance into another. The former is fact; the latter we maintain is, if not fiction, at least "not proven." Mr. Pettigrew has not yet furnished us with any evidence of this alleged fact. Nor do we see how in the nature of things it can possibly be proved; for such a fact would simply mean that bees have a fund or store of saccharine matter in their stomachs, which, like the "doctor" with which, as is alleged, wine merchants improve their poorer wines, bees supply the defect of quality in the sweet syrup they collect from the flowers, and manufacture "the perfect honey" of which Mr. Pettigrew speaks.

Well, but how do we account for the change? We reply that it seems to be the most easily accountable thing in the world. We are fully convinced that evaporation is the chief and perhaps the sole factor in the business, although it is of course possible that the bees may themselves reject a good deal of the honey they have too hurriedly collected (not that we hold such an opinion) during the excitement of the period of glut, and there may be

(probably there is) some chemical change perpetually going on owing to the high temperature of the hive, which affects the consistency of the honey and even its quality. But this is very different from Mr. Pettigrew's contention.

We maintain that the great heat of the hive is quite sufficient to account for the change we speak of, whether it be chemically or otherwise affected by it. The evaporation which goes on in a temperature often approaching to 100° Fahrenheit must be enormous. Hence the watery element in the crude honey is largely diminished in a very short time, while the saccharine matter is left greatly predominant. We are satisfied with the reasonableness of this explanation, which has often been given in these pages by close observers of the honey bee.—THE WRITER OF THE REVIEW OF "HANDY BOOK ON BEES."

### ANNUAL MEETING OF THE BRITISH BEE-KEEPERS' ASSOCIATION.

THE annual meeting of this useful Society took place at the National Chamber of Trade, 446, Strand, on the 16th inst. In the absence of the President, the Baroness Burdett-Coutts, Mr. T. W. Cowan occupied the chair. An admirably drawn-up report, which has been previously circulated, was taken as read, put from the chair, and unanimously adopted. Votes of thanks to the retiring officers and Committee, proposed by Mr. Littleboy and seconded by Bishop Tozer, and to the Council of the Royal Society for the Prevention of Cruelty to Animals, proposed by Mr. Cheshire and seconded by the Rev. G. Raynor, followed.

After the election, which was in every case a re-election of officers, the result of the voting for the Committee was declared. Mr. T. W. Cowan, 195; Rev. G. Raynor, 188; Mr. F. R. Cheshire, 181; Rev. E. Bartrum, 180; Mr. J. Hooker, 175; Dr. L. Beale, 172; Mr. C. Abbott, 143; Mr. Whealer, 98; and Mr. Jonas, 96. The last two are new members. The Secretary now sketched some plans of operation in connection with agricultural and horticultural societies, which will in itself prevent the Committee of 1881 from being idle. Some small changes were made in the rules, the most important being an alteration of the date from which subscriptions shall commence, this being formerly May 1st, but now made January 1st. Upon this matter the decision was not by any means unanimous. Mr. Lyon proposed to the Committee the offering of prizes for improved methods of packing honey; and the Rev. E. Sisson suggested that amateur classes should be created, as the amateur had no chance with the professional bee-keeper and hive-maker, and that amateur hive-making should be encouraged by special prizes. Mr. Cheshire remarked that careful observation had convinced him that in honey classes the amateur has nothing to fear from the professional bee-keeper and hive-maker, who was almost always in matters of honey conspicuous by his failure, but that he thought the suggestion with regard to hives was a very good one.

After tea and coffee the quarterly conversazione took place, when Mr. Lyon read a paper on

#### CHEAP BAR-FRAME HIVES FOR COTTAGERS' USE.

Bishop Tozer, who was voted to the chair, introduced Mr. Lyon with some gracious remarks upon the pleasure he felt at being present. Mr. Lyon first drew attention to the difficulty of introducing the frame hive on account of its cost, referring to a list of a Scotch firm in which the lowest price quoted is 5s. for a complete hive containing eight frames Woodbury size with a roof; adding that the customers of hive-makers are with rare exceptions clergymen, gentlemen of means, well-to-do tradesmen, and others who can well afford an outlay of a few shillings for each hive, but that the price even when reduced as much as competition can reduce it is for the poor cottager prohibitive. He suggested bought boxes as a remedy, remarking, "As we cannot with the means and tools at our disposal make our boxes, we must look about for some which have already served the purpose for which they were made, and can therefore be sold for less than the cost of making. The very essence of the bar-frame system is the complete interchangeability of the frames. Every frame in every hive in our apiary should be interchangeable with every other frame. It is therefore necessary in the selection of our boxes that they should be always without difficulty obtainable of uniform size and shape.

"In looking about for suitable boxes I have tried wine cases, brandy cases, and milk cases, all of which are too shallow. Milk cases, however, make very good super covers or roofs. The cases in which preserved meat is imported are very good and strong, but unfortunately each packer uses a slightly different shape. The only boxes I have found to be always uniform are lobster boxes—i.e., boxes in which preserved lobster in tins has been imported. These boxes are 18½ long, 12¼ wide, and 9 deep, well made of good wood planed outside, 1 inch thick at the ends and full half an inch at the side; they have a lid and a bottom, and cost 3d. or 4d. each. Of all the various shapes and sizes of hives which have been introduced the Woodbury having ten frames each 13½ inches by 8½ inside measure, giving 1147½ superficial inches of comb when filled, has been found the most suitable for general use. The lobster box will carry twelve frames, each 11¼ by 8½ inside measure, which gives exactly 1147½ super inches of comb, the same as the Woodbury. Comparing the

size another way I turn to our Manual, page 18, and find a hive containing 2000 cubic inches mentioned as a desirable size. The lobster box contains 2039 cubic inches. There is another advantage which is not to be overlooked—viz., that the frames being only  $11\frac{1}{2}$  inches inside measure will be filled from side to side by any comb from an averaged sized skep except the outside ones, which, as they are nearly always store combs, are seldom transferred without piecing. I have here a hive or body box made from one of these boxes. The alighting board is made out of a piece of the lid, and so is the batten across the bottom. The strips at the ends are from waste in cutting the frames. As we cannot afford to pay for labour we must show our friend how to make his frames with little trouble and tolerable certainty that he cannot go wrong. We now require a tool which is not likely to be found in his possession—viz., a “cutting gauge,” cost 10d., and a bradawl, 2d. I have here a piece of best pine wood, it is “five-cut”—i.e., five cuts, giving six boards out of a plank 3 inches by 9. A plank costs in London 4s., and each cut 3d., making 5s. 3d. for 72 feet, or say 1d. per foot of five-cut board; perhaps it may cost a little more in the country, but not, I should suppose, more than  $1\frac{1}{2}$ d. per foot. Being unwilling to turn this room into a carpenter's shop I have cut it off to the proper length—viz., the width of the body box outside. I lay it on the hive and with a pencil mark along both sides thus,\* and then mark off a quarter inch inside this line on each end. I now set my gauge to  $1\frac{1}{2}$  inch bare and cut off slips from my pine thus.† There is a reason for using pine—viz., it is free from knots and crooked grain, which would throw out the gauge. I now with my knife cut a notch at each end at the mark,‡ and set my gauge at a quarter inch. I cut out the two pieces,§ thus leaving the ends of the full width to form a shoulder, and our top bar is made. I now take another piece of pine already cut off half an inch less than the depth of the box, and setting my gauge to the width of the top bar I cut off strips to form the side pieces. The pieces§ which came out of the top bar will form the bottom rail. Before nailing together, however, we must provide for the preservation of the quarter-inch space §§; this I do by making a hole with my bradawl diagonally outwards from the marks (which show the width of the inside of the hive) through the top bar, and when nailed together driving a French nail through the hole into each of the side pieces. Here is a frame completed. You will observe that there is very little scope for propolis, as there is no step or rebate on the under side, and no part of the shoulder projects inside the wall of the hive. The quilt or covering for the frames may be any old material; a few darns and patches will not affect its usefulness, and for additional warmth in winter a bag of chaff or of bruised and dried ferns will do. I have bought at a rag-shop a lot of old carpet at 1d. per lb. which answered capitally. The division board is made of part of one of the lids, the roof is formed of another lobster box with fillets cut from the lid nailed round to keep out the weather.

Fig. 34.—A, B, The points at which the notches are made by the knife. The part between A and B is removed by the cutting gauge, and so the top bar of the frame is formed. The shoulders are left of about true size, but the length of the bar has been much reduced for the sake of convenience.

“The hive is now complete with the exception of the supers. As to these I think it best not to attempt too much at first. Let us get bar-frame hives adopted if we can. Let us show the cottager how he can obtain a bar-frame hive at less than the cost of his favourite skep, and when the long time the former lasts is considered it will be far cheaper and he will be willing to adopt it. You notice that I place the door at one end and the frames across the hive, so that the greater part of the honey will be stored at the back with a fair chance of its being uncontaminated by brood, and with the certainty of its being taken without destroying the bees—a vast step in advance. I will now reckon the cost. We have two boxes at 3d., or say 4d. each, 8d.; one (5-cut) pine board cost 1s., but it makes frames for two hives; cost for one hive, 6d.; nails, pitch, and paper not more than 4d.; total, 1s. 6d. Then the cutting gauge will cost 10d., but this is plant. I reckon nothing for materials for quilt, as any old clothes which would be burnt or thrown away will do; nor do I reckon anything for the stand, as this must be provided for a skep (indeed a skep requires a floorboard, and our 1s. 6d. hive has one). Four stakes driven into the ground make a fair stand. This small sum of 1s. 6d. need not be expended all at once; one week a box may be bought, another the board, another a second box, and so on as the cottager can spare a few pence.”

NOTE.—Regard to space has forced us to excise some of the less essential portions of this paper, while the lengthy and interesting discussion which followed will appear in a future issue.

\* The mark was made on the under side of the board and against the top edge of the body box.

† The gauge was made to cut into the stuff from each face when the slip  $1\frac{1}{2}$  inch wide was broken off.

‡ The pencil mark previously made.

§ The pieces between A and B (fig. 34).

§§ The quarter-inch space between the side of the hive and the side of the frame, essential to prevent the bees fixing by propolis.

## TRADE CATALOGUES RECEIVED.

King & Co., Avenue Road, Woodford, E.—*List of Vegetable and Flower Seeds.*

A. J. Main & Co., Queen Victoria Street, London.—*Illustrated Catalogue of Iron Roofing and Shedding.*

**Books (A Reader).**—Concise cultural notes on the plants you name, and many others, are included in our “Greenhouse Manual,” which you can have from this office post free, price 10d. Reliable articles on some of the plants you mention are contained in Carters’ “Practical Gardener,” the price of which you will find in our advertising columns. You cannot err by obtaining both of these books.

**Vegetable Trials (D. McD.).**—No systematic reports of the trials of Brussels Sprouts and Parsnips at Chiswick have been published, but you will find a note on the vegetables grown there in 1880 on page 461 of our last volume. If we can obtain information on the other question you have asked it shall be published.

**Showing Peas (J. S.).**—You have permitted an extraordinary length of time to elapse before asking to correct what you deem a mistake. We shall be glad to have some particulars of the variety you mention, and to know your name and address, which you have failed to send, and your letter shall have our attention.

**Stephanotis Unhealthy (C. S.).**—Your plant has sustained a severe check by the excessive cold of the winter, the temperature you name having been often  $10^{\circ}$  too low for maintaining the plant in a fresh healthy state. You have done quite right by endeavouring to stimulate root-action, and if you provide a warm genial temperature to promote fresh growth the plant may recover its lost vigour. We are unable to suggest any other means for its renovation.

**Blood Manure (Idem).**—We know of no better mode than that given in the receipt to which you refer; but probably the quantity of acid may require to be increased. The blood should stand for a time, and only the coagulated portion be used. When prepared it may be used the same as guano, sprinkling it on the surface of the soil between the crops at the rate of an ounce or a little more to the square yard.

**Insects under Nut Trees (F. J.).**—These are mites belonging to the family Collembola, apparently *Smyntus fuscus*. Feeding upon decaying wood or the fungi which suddenly appear in damp weather, these insects congregate in vast numbers, and are sometimes called “ground fleas.” In this instance the species would probably do no harm, but some of the Collembola attack young plants in frames, such as the Cucumber, being usually carried in with manure.

**Pruning Holly Hedge (S. M. M.).**—Your hedge may be cut into the form desired at the present time. The knife is a much better implement than the shears for this work, but the process is necessarily much slower. When the shears are employed the leaves are severed, and the hedge has then an unsightly appearance for a long time. The leaves of Hollies and Laurels should never be cut, but the growths that are not required should be removed with a knife, the leaves that are left being uninjured. Early September is also a good time for trimming evergreen hedges. The tan may be spread thickly under the Gooseberry bushes when the buds commence swelling, or just before the leaves expand.

**Glazing Without Outside Putty (Several Correspondents).**—All the letters on this subject were forwarded to the writer who advocated the practice in our last volume, and his reply to them is published on another page of our present issue. When this mode of glazing is properly carried out we know it is good, as the roof is rendered perfectly watertight, and less cost is incurred in painting and repairs than when top putty is used. We know from experience that more labour is involved in stripping off old putty when the wet gets under it, and adding fresh, than in painting the roof.

**Fowls in Garden (J. Miller).**—Your proper mode of procedure is to give the owner of the birds a written notice that you will hold him responsible for the damage they do in your garden, and if he does not adopt means to keep them in his own enclosure you can eventually sue him in the County Court, and recover the amount of the loss you have sustained by the birds eating your Currants. You cannot legally destroy or injure the fowls.

**Cats Disfiguring Flower Beds (E. T. H.).**—We do not know a mode of preventing cats scratching in flower beds, but if the surface of the soil is kept wet it has less attractions for the animals. Some people in towns strew pepper on the flower beds where cats abound, and others sprinkle the soil lightly now and then with paraffin. If any of our readers can suggest a remedy for the evil in question we will readily publish it.

**Winter-flowering Plants for the Greenhouse (E. C.).**—The plants you mention are all useful for the purpose, especially the Libonias, which may be grown in large quantities. There is no difficulty in maintaining a good display of flowers in a greenhouse during winter if another structure is at command for advancing the plants in, but without that the list is necessarily limited. To forward in heat you may have a variety of bulbs, such as Hyacinths, Tulips, and Narcissuses, with early varieties of Azaleas, Lilac, *Orobis vernus*, *Justicia speciosa*, *Kalmia glauca* and *K. latifolia*, some *Rhododendrons*, especially the handsome hybrid Countess of Haddington. Plants that are indispensable for the greenhouse at such a time of year, and which come in early without any forcing, are *Helleborus niger*, which may be grown in pots or baskets, *Erica hyemalis*, *E. Wilmoreana*, *E. melanthera*, *Azalea amoena*, *Acacia platyptera*, *A. longifolia*, *Spartanilla africana*, *Primulas*, *Cincarias*, *Cyclamens*, and *Zonal Pelargoniums*.

**Plants to Flower in August (G. W. A.).**—To have the plants in flower at the particular date you mention they must be kept moderately dry and cool, giving careful attention in insuring thorough ripening of the wood before resting, and supplying abundance of water after starting them. The plants may be

started about the following times:—Allamanda Hendersoni in early April, Bougainvillea glabra and Clerodendron Thomsonae at the commencement of June, Stephanotis floribunda in May, and Rondeletia speciosa in April. Much care will be needed to have them all in good condition at the exact period you name, as some will probably start more quickly than the others, and you must then exercise your discretion in retarding them.

**Trees Injured by Rabbits** (*A Lady*).—Perhaps the simplest plan you can adopt is to secure some thick plasters of clay and fresh cow dung round the stems of the trees, and if the bark is not very much injured the wounds will heal. Old canvas will do for wrapping round the stems, and if this is dressed with tar or paraffin the rabbits will not touch it. Tar should not be applied to the stems of the trees, as so used it is often injurious. Liquid grafting wax is also a very useful application for covering wounds. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly the alcohol is prevented from evaporating. Take of rosin, 1 lb.; beef tallow, 1 oz.; spirits of turpentine, 1 tablespoonful; alcohol (95 per cent.), 6 ozs. Place the rosin over a slow fire, when melted take it off and add the beef tallow, stirring it constantly; let it cool down somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot much will be lost by rapid evaporation; if, on the contrary, it is too cool it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If in course of time it becomes too thick the addition of some alcohol will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling or hot water to accomplish this.

**The Auvergne Pea** (*W. B. Notts*).—The Auvergne Pea was introduced from France some years ago by the Royal Horticultural Society, but although it very far surpassed every other variety of White Pea then in cultivation, it never became widely known or generally cultivated. It is a most characteristic variety, and always easily distinguishable by its long and curved pod. The plant is of a moderately strong habit of growth, producing a single stem from 4 to 5 feet high, according to the soil in which it is grown, and bears from twelve to fifteen pods on each. The pods are sometimes produced in pairs; when fully grown they are 4½ inches long, and over half an inch broad, tapering towards the point and very much curved as shown in fig. 35; they contain from nine to twelve peas, which are very closely compressed, and are the size of the Early Frames. Even the small pods contain as many as from seven to nine peas in each. The ripe seed is white. It is a second early Pea, useful and productive, and it succeeds better in a dry soil and season than any variety we have grown. It much resembles Dickson's Favourite, but the plant is stronger than that variety, and a few days later. The Auvergne is synonymous with the White Scimitar and White Sabre, under which names it was grown many years ago.

Fig. 35.

**Seedling Azaleas** (*G. Russell*).—The flowers you sent are very beautiful and appear to be intermediate between the parents named—i.e., amœna, pollen parent, La Victoire, seed parent; and if the habit is, as you say, that of the former, the cross is a decided acquisition. Some of the flowers resemble La Victoire in colour, while in form they are like amœna but larger; in others the characters seem reversed. The hose-in-hose flowers are especially notable for their symmetry of form and distinct colour, which seems to possess a peculiar shade of purple, suffusing the salmon-pink hue that chiefly prevails. You have certainly been fortunate in obtaining this cross, which is quite in the way of those forms obtained by Mr. Carmichael a few years ago.

**Vegetables in India** (*X.*).—The remarks to which you refer occurred in the preface to the eighteenth volume of the *Cottage Gardener* in 1857, where it was stated that at one of the exhibitions of the Calcutta Horticultural Society the following vegetables were

exhibited:—Celery, Cabbage (Red Drumhead and Savoy), Spinach, Turnips, French Beans, Endive, Carrots, Lettuces, Red Beet, Artichokes, Potatoes, Tomatoes, Peas, Cauliflowers, and Watercresses, all of which it is added "would not have shamed a market gardener at Fulham."

**Amaryllis Culture** (*Tyro, Essex*).—The plants require abundant moisture and nourishment when growing, but after the foliage has attained its full size they require no more water than just sufficient to prevent the leaves flagging. Perfect drainage must be secured. Strong hazel or yellow loam free from iron, with a little sharp sand, is all they need in the way of soil. Leaf soil and other vegetable matter, which slowly decompose, are to be avoided. Too much heat when growing is injurious, as it causes drawn foliage and weakens the bulbs. They require as much heat when at rest as when growing; and though this may appear to some the reverse of good management, it is only what they receive in their native habitats. The roots remain on the bulbs throughout the year; taking them out of the pots when at rest, therefore, robs the bulbs of that which Nature has provided to collect food for the support of the scape of flowers. Deep, narrow pots, 8 inches in depth, and double the diameter of the bulb, are the best description to grow them in. Frequent potting and plenty of pot room is their bane, and potting a plant of this kind because the pot is full of roots will prevent its flowering. The pot never can be too full of roots, as the bulbs flower all the better for being cramped; and so long as the drainage is perfect and the soil sweet, it is immaterial how long the plants are kept in the same soil and pots, if only the offsets are removed and potted, thus preventing their exhausting the parent. Examine the pots at once, and see that the drainage is all right. Having made it perfect replace the ball in the pot, adding a little soil upon the drainage if the plant or bulb be too low,

and gently stir the surface of the soil around it; if any fresh soil be added it should be dry, and the bulb will be none the worse if it be covered to the neck. Some of the tender kinds decay; unless the bulbs are thus covered they are apt to decay at the base. In looking to the drainage and stirring the surface care should be taken not to injure a single root nor break the ball, for that is robbing the plant of so much absorbent surface, and is a direct way of weakening the bulbs. Place the pots on a shelf about 1 foot or from that to 18 inches from the glass, and if the temperature range from 55° to 60° it could not be better. The situation should be light and free from drip. No water must be given until the leaves appear, for the concentrated juices of the bulb are sufficient without the aid of water, when they must be slightly watered, gradually increasing the quantity as the leaves and scapes elongate. When the scape has risen 6 inches give a plentiful supply of water, and let every alternate watering be weak liquid manure, or, what is more safe for an amateur, 1 oz. of Peruvian guano dissolved in a gallon of rain water, and with this water the plant every other day, and the intervening day with pure water. All waterings to be applied a few degrees over rather than a few below the temperature of the house; enough to be given to run through the pot, and if it does not do this without having to stand on the surface, or is a long time in doing so, the soil is either dust-dry or sodden, or the drainage is choked. Examination being made, the defect, whatever it be, must be remedied at once. The leaves should not under any circumstances be suffered to flag at this stage, and the atmosphere must be kept moist by syringing night and morning every available evaporating surface with water of the same temperature as the house. Air should be given on all favourable opportunities, but cold currents must be studiously avoided.

**Names of Fruits** (*George Picker*).—No. 1, Golden Nonpareil; 2, Golden Pearmain; 3, Norfolk Bearer; 4, Winter Peach. (*J. Bakewell*).—1, Cannot be identified; 2, Boston Russet. (*R. Masters*).—1, D'Arcy Spice, called also Spring Ribston and Baddow Pippin; 2, cannot be identified. (*A. A. G.*).—We are unable to name your Apple; the specimen appears imperfect. Many Apples that have been sent have been so much injured by frost as to quite change or destroy their flavour, thus depriving us of one important test in identification.

#### COVENT GARDEN MARKET.—FEBRUARY 23.

TRADE keeps quiet, our market being bare with the exception of imported goods, large quantities of Canadian Apples still reaching us, but in unsatisfactory condition.

#### POULTRY AND PIGEON CHRONICLE.

#### THE COMPARATIVE ADVANTAGES OF FATTENING BULLOCKS AND SHEEP.

(Continued from page 141.)

PREVIOUS to our entering into any minute investigation of the cost and results of our method of feeding and fattening cattle and sheep we had always entertained the opinion, but it was not general at that time amongst farmers, that sheep stock barely paid for their keep, and that after we had charged the roots, &c., at feeding value we had only the manure left as compensation. We also supposed that the bullock-feeding was worse than sheep-feeding, because of the extra cost in the cartage of roots and manure returned to the land, and so it would prove no doubt were it not that the system of feeding exhibited by these com-

parisons had been carried out. The chief point to which we wish to call attention is the diminished quantity of cake used, and the fact of feeding with straw instead of hay; for instance, give 2 lbs. more cake per day, and a fair allowance of hay to each bullock, and the item now standing as profit would be lost without advantage in return. We contend that 4 lbs. of best linseed cake per day is as much as the stomach of the animal can assimilate and convert into meat advantageously, for we have found that hay clogs the stomach, as we have never known a straw-fed bullock refuse either roots or cake, which they frequently do with hay feeding. An objection is sometimes raised to bullock-feeding by stating that the land requires the tread of the sheep and the whole root crop consumed upon it, and this is true upon light and poor soils; but upon the mixed or dry friable loamy soils in good condition one-third at least of the root crop can be spared for bullock-feeding, the remaining two-thirds being fed off by sheep on the land with oilcake, or corn and hay. This will leave such soils quite rich enough to produce a full crop of Lent corn, and the roots removed for consumption by bullocks in their boxes will convert large quantities of straw into rich manure to be applied to other parts of the farm.

We wish here to draw a contrast between the effects of sheep manuring and box-made dung. It is well known to practical farmers that sheep in the winter months do not always manure the land regularly. For shelter in bad weather they often huddle together under hedges or on the lee side of the hurdles, and therefore drop their dung in excess in those parts, whereas other parts get little or none. Not so, however, with the box manure, for it can be applied at the discretion of the farmer upon those fields or parts of fields in such proportions as may be necessary. These observations do not apply with full force to stall feeding, because there is usually more or less waste of manure, arising from its exposure to drought or wet weather, and frequently by undue and excessive fermentation in the heap; but in box-made manure, when it is properly managed, there will be no loss, for when earth is placed at the bottom of the boxes the liquid manure is absorbed, and the accumulating mass of dung is always in a fit state for removal and application to the land, and can be allowed to remain in the box until required for use without loss. We wish also to observe that feeding sheep in the open field is often attended with losses consequent upon their exposure, &c., and we have also experienced severe losses from inflammatory disorders, also diarrhoea and epidemic lameness, foot rot, &c. On the other hand, we consider neat cattle kept under cover subject to but little loss generally. Although pleuropneumonia has in some instances prevailed, it is quite an exceptional disease, particularly among box-fed animals, and during our own experience we have scarcely ever lost a fattening bullock. It may probably be asked how boxes are to be obtained for cattle feeding upon farms in general. We reply, Take the barns as we have done for the purpose, let them be partitioned at a small expense with larch poles, and they will prove better accommodation than any buildings usually erected for the purpose of box-feeding. For further information upon accommodation for cattle we refer the home farmer to articles in this Journal under date of the 16th, 23rd, and 30th of September last.

Now threshing by steam prevails the corn and straw is better in stack than in barn, and nearly all the farms in the arable land districts have barns; they are therefore provided with the space for box-feeding a good number of fat bullocks. Mr. Lawes's experiments, as given in vol. xxii. of the "Journal of the Royal Agricultural Society," strongly support our experience, and upon which our calculations have been made—namely, that his bullocks show about the same gain or increased value, 16 lbs. of beef being the average increase per week, and yet it includes some animals which did not thrive, their gain being much below the average. Still we cannot ask the home farmer to expect results equal to our own or Mr. Lawes's, unless the animals are of good breed and forward in flesh at the time of purchase; besides, it is always necessary when a bullock does not thrive to sell it for what it will fetch, the first sacrifice being always the least. If we were asked how we would proceed with a poor bullock, we should feed it for three months at a cost of not more than 5s. per week. We should, however, much prefer taking an animal in high condition and pay a price accordingly. There are, in fact, many of our farming operations which should depend upon statements like those brought forward here. For instance, the straw grown on the farms is often greatly neglected, and is never made into good manure where sheep only are kept to consume the root crops. Again, bullocks could not usurp the place of sheep entirely upon the farms where a full quantity of roots were grown, because there would not be straw enough produced to feed and litter them, and the same result would obtain in case of house-feeding the whole

stock, supposing the food to be divided between bullocks and sheep, each being under cover.

We shall now refer to the evidence afforded by eminent practical men showing that sheep, either as a stock flock on the hill farms or grazing and fattening flock on the vale farms, are kept at a loss, in accordance with our own statement of the feeding of dry sheep, either tegs or wethers. Taking the result of keeping a breeding stock flock first. We must notice a paper furnished to the "Journal of the Bath and West of England Society" by Mr. E. P. Squarey, on "The Hill Farming of Wiltshire and Hampshire in 1861." In this we find a most elaborate and practical statement of the result of sheep-farming, illustrated by a farm of 800 acres, managed, according to the custom of the chalk hill districts, by a debtor and creditor account of the sheep stock for a year, which shows a loss upon the transaction of £111, without charging wear and tear of hurdles, &c., and cost of superintendence. We must also give the result estimated by a number of practical members of one of the most important farmers' clubs in the kingdom of the feeding and fattening of two hundred Hants Down ewes and their lambs, together with one hundred tegs, all fed for the butcher upon a vale arable farm. A minute and detailed debtor and creditor account exhibits a loss on the transaction of £62. There are no more and important accounts to be found than those we have brought forward; but it must be borne in mind it is without any reference to the value of the manure left on the land, for that would vary greatly according to circumstances, and as that is not part of our subject now it will be dealt with at a future time. In referring to the experiments relating to the comparative consumption of bullocks and sheep the most valuable we can find was carried out at the Duke of Bedford's some years ago. The average weight of the sheep experimented upon was 147 lbs., the animals belonging to various breeds. The bullocks, which were all well-bred animals (Herefords and Devons) weighed on an average 1415 lbs., being a proportion of nine-and-a-half to one in weight. The sheep consumed 6½ lbs. of oilcake each per week, and the oxen 43 lbs., thus the average quantity consumed by an ox and sheep respectively was in the proportion of about one to four. Now this experiment, as well as others we could furnish if necessary, most completely accords with the food as estimated in our debtor and creditor account as given in the first part of this article.

After having stated thus much to prove that abundance of evidence exists to justify all our estimates we must, however, be prepared to expect some diversity of opinion, for some farmers may say that 1 lb. of oilcake per day is too much for a sheep. We, however, are not disposed to quarrel about it, for we can only state our own experience and that of many other farmers that if half a pound of cake per day only was given the increased value of the animals at the end of twenty weeks' feeding would be only 15s., whilst with 1 lb. of cake it would be 20s. We have also noticed a variety of experiments of feeding cattle and sheep under the like conditions by many good farmers. But under our subject they are treated differently—the oxen under cover, the sheep in the open field; but it should be remembered that it is no suggestion of ours, but it represents a general practice upon arable farms in nearly every district, and we have simply taken the facts as we found them. In our statement the cases between the ox and the sheep are as wide as the poles asunder, the cattle being fed under the best possible conditions, and the sheep under the worst. In estimating the casualties to which both classes of animals are exposed as single and individual lives the losses of sheep we reckon as eight to one compared with oxen. Now these facts, the result of great experience, furnish strong arguments in favour of bullock-feeding as compared with sheep. We have, however, not thought it desirable to estimate their money value, as it would only serve to render a difficult subject still more intricate and complicated. After all the statements we have made we make no doubt but many farmers who have viewed these matters from various standpoints will be induced to calculate in their own way and in their own case, and thus fulfil our object in introducing it in the peculiar manner shown by our heading of the subject; and we make no doubt that business and practical men will agree with us that it may be desirable to feed bullocks under cover with one-third of the roots grown, and sheep with the remainder in the open field upon soils in general.

#### WORK ON THE HOME FARM.

*Horse Labour.*—A very important period of the year has now arrived for horse labour, and this or steam culture may now be applied with great advantage in various ways, but none more important than cultivating the land in readiness for sowing Lent corn where roots have been fed off by sheep. We wish, however, to call special attention to the cultivation of gravel or sandy soils, because, if properly scarified so as to break up the entire surface with regularity, it is by

no means necessary to plough the land, although it is a common custom to do so. We find that by scarifying a tilth sufficient to bury the seed by drilling is obtained, and the land is not so much affected by a dry season. When the land is scarified the weed seeds which vegetated on the surface during the growth of the root crop were destroyed; and as we only deal with the surface soil, very few weeds will appear to the injury of either the Lent corn or the Clover. The grass lands may now be rolled and laid up for a crop to be mown for hay, the sooner the better, before the land becomes too dry. As we must sow Beans and Peas it is well to be prepared with the seed beforehand, otherwise the best seedtime may be lost; besides, if the seed has to be purchased, the sort or quality of seed required cannot always be obtained at a moment's notice.

Stable management of farm horses has not only been referred to occasionally under the work of the farm, but was the subject of a special article in this Journal on January 10th and 17th, 1878. As, however, we have many new readers we again call attention to the necessity of attending to the health of horses. This is, however, unfortunately, almost an impossibility as the stables exist at present on many farms, for we find the floors of the stalls covered with large stones of various sizes and laid most unevenly; this is, of course, very bad for the animals, although littered with straw. In fact, knowing the pain they suffer in lying down, they do not often attempt to take the rest which they naturally require at night. This can readily be altered by a plan we adopted in our stables, one that was followed by many of our best farmers years ago, and which we recommend with confidence—viz., to take up the old rough stones and excavate the earth about 18 inches in depth; we then refill the space with dry screened loamy soil rammed down firmly, upon which the animals are allowed to stand, the dung being removed daily as usual. After a few days this earth becomes quite firm and clean for the horses to stand upon, but still absorbs all the urine. By this means a pure atmosphere in the stable is obtained at all times, until the earth becomes saturated and begins to give off the fumes that are so offensive and detrimental in ordinary stables. The earth will require changing twice a year—at about four months in the summer when the animals eat green fodder, and at eight months after they have lived principally upon dry food during the winter. Since we have adopted this plan we have generally had healthy horses free from blindness, broken wind, greasy heels, and other complaints incidental to ordinary stables, where the floors are rough and sodden straw accumulates between them, rendering the air foul. With earth floors horses living in pure air will be capable of work several years longer, thus saving the animal loss for the time, which amounts to from £3 to £4 per annum per horse. We shall refer to this subject again shortly.

*Hand Labour.*—Forking out Grass, Docks, &c., from the root crops before feeding off with sheep should now be continued. As the seasons have lately been unfavourable, many instances of land not quite clean are still frequently met with. Men will now be required on those farms where draining is needed, for the first drying winds which occur will show very plainly the parts of fields which are too wet for profitable culture: the dry land will retain a white appearance, and the wet portions a dark colour. It will then be easy to set out the work by spars and stakes, so that in case it cannot all be done immediately it may be resumed when convenient. We are, of course, alluding to under a fallow or cultivated surface, because it is only under such circumstances that the variations of colour of the land can be distinctly seen. The injury done to Swedish Turnips where the bulbs have been left in the land during the severe weather in January has been general, varying only in degree—the ripest and most matured crops having suffered the most, and the latest-sown the least, because the latter were in a growing state when the frost set in. The frost, however, was so severe before the snow came, that the latter afforded no protection in many cases. The loss, therefore, of a considerable portion of the Swede crop must be seriously felt before the grass is ready in the spring, for the water meadows, although the grass in them is not so forward as in some seasons, will prove very valuable. This is also one of those seasons which go to prove that Mangold is the most to be valued of all our root crops; for when properly secured and preserved they are good food for all kinds of stock during every month in the year. For many years it was our practice to use them all the year; in fact we grew only Carrots and Mangold with a few Cabbages, and have often begun feeding our sheep stock with Mangold of the same year's growth in the months of September and October in the open field. The Mangolds in heap should now be looked over and examined. If any bulbs should be frosted or rotten from other causes the affected ones should be removed, in order that the decay, although partial now, may not become general, and affecting the whole further on in the season. After defective roots are taken away they may be used for what they are worth, and the heaps made up into form again and rethatched, to be preserved for use during the spring and summer months. In many cases on the hill farms the loss of the Swede crop will render necessary a considerable outlay for corn or cake to maintain the usual stock. Now this is one of many sacrifices which have to be made in keeping a breeding flock of sheep, and which upon the average of seasons greatly reduces any profit which the breeding of sheep may sometimes promise. In the early frost of 1859, if we recollect rightly, when the Mangolds were damaged in all parts of the kingdom by the frost which happened in the second week of October whilst the

roots were in the ground, various modes of using them for feeding cattle were resorted to, to make them palatable, such as giving bean and barley meal, also maize meal, and we found the decayed or partially decayed roots were not injurious to the stock, although having less feeding value.

## ADVANTAGES OF A HOME FARM.

### DAIRY COWS.

Cows and the dairy take a place of considerable importance upon the home farm, a regular and abundant supply of milk, cream, and butter being indispensable. With a herd of cows restricted to a number calculated to afford only a moderate surplus over the quantity of its produce required for the ordinary daily wants of a household, this is occasionally found to be a matter of difficulty, for disappointments and failures are certain to occur in every herd however carefully selected and bred; and what is most vexatious is the well-known fact that the best cows fail soonest—best, in the sense it is here used, meaning a deep milker, quiet and kindly, with which we have no trouble till indications of failing powers and debility appear in the guise of a tendency to barrenness and excessive leanness. Then, too, there is an uncertainty about heifers, of which one or two should be brought into the herd every year. At the present time I have four heifers in calf, and shall consider myself fortunate if out of that number two prove really valuable cows. Occasional losses also occur, and it is well, therefore, that rules as to number should be somewhat elastic. It is better to have butter to sell than to have to buy it, as it is precisely in midwinter, when it is most expensive, that the supply is apt to run short. This is especially true in reference to select herds of pedigree cows restricted to one particular breed. Fond as I have reason to be of the hardy little Kerrys, yet it must be acknowledged that a mixed herd has been found to answer best, most of the cows yielding rich milk in a comparatively moderate quantity, and the remainder being deep milkers with milk of only medium richness, but nevertheless admirably adapted to maintain a supply for table and culinary purposes. Take for example the yield of an ordinary Jersey or Alderney, which may fairly be stated as ten quarts daily, and it is at once seen to be the reverse of economical to depend upon such cows for the forty or fifty quarts of new milk required every day in a large establishment. For this purpose I prefer milky Shorthorns, or Shorthorns crossed with a good strain of Channel Island cattle. Deep milkers generally impart the same valuable property to their progeny. I have three heifers, two to come into the herd this year and one next year, all descendants of a famous old cow which yielded milk abundantly, and was so well known that when she began to fail from old age and had to be withdrawn from the herd, there was no difficulty in disposing of her at a comparatively high price. The oldest of her descendants is an equally deep milker, and is at the present time in full profit, having had her third calf recently.

An important fact to remember is that the quality and quantity of milk depends in a considerable degree upon a cow's food. Underfed cows never succeed. The milk is poor and thin, and diminishes in quantity very soon after calving. The calves, too, are undersized and weakly, and the cow is usually a mere "bag of bones" for the greater part of the year. Now, without plenty of good food there cannot be a well-sustained yield of milk. It is an excellent rule never to put a cow in its stall for milking without giving it a feed of bran, even at midsummer. It is an inexpensive kind of food, all cows like it, and it is invigorating and nourishing. I always use it in winter; and when the cows are first turned out of the yard upon grass I have tried the effect of withholding it, and speedily perceived a falling-off in the quantity of the milk. This could not be caused by a scarcity of grass, for grazing does not begin till it is plentiful. No greater mistake can be made than to place cows upon a bare pasture either early or late in the year; and yet how frequently it is done! and the poor half-starved animals are walking and munching the whole of the day to very little purpose. Let the milking begin at 6 A.M., and the cows be out on the pasture soon after seven, and if it is in the condition it ought to be they will have procured enough food and be ruminating by ten, or soon after. When grass runs short in autumn take them altogether into a warm well-littered yard, with a large deep open shed on one side of it with a hay rack. Some cows are more tender than others, keeping much in the shed, others feeding from the central rack in the yard, and almost all going into the shed during rain. But if there is only a cow house, out of which they are shut during the day, and no open shed, they are apt to suffer from heavy rain and cutting blasts of wind which sweep round buildings into yards with much force.

—EDWARD LUCKHURST.

## VARIETIES.

**THE MECCHI FUND.**—The following letter has been received by Mr. Samuel Morley, M.P., in reply to an application addressed by him to Mr. Gladstone in the interest of the "Mechi Fund":—"I shall be prepared to recommend a grant of £200 from the Royal Bounty Fund for the benefit of Mrs. Mechi. I have learned with satisfaction that the subscription which you mention has been undertaken on her behalf, and I wish it success, as an acknowledgment of Mr. Mechi's great and long-continued services to British agriculture. —W. E. GLADSTONE."

— **SUTTONS' FARMERS' YEAR BOOK.**—This annual which, besides giving instructions for the cultivation of some of the principal root and forage crops, contains a concise calendar of farming operations with special and excellent articles on the vermin of the farm, and the chemistry of farm crops, which may be read with advantage by those engaged in agricultural pursuits.

— **THE FORMATION OF PERMANENT PASTURES.**—This pamphlet of Messrs. Webb & Sons, of Wordsley, Stourbridge, contains practical instructions on the drainage of land, preparation of the soil, seeds and sowing, with notes on the after culture and management of pastures, and a list of forage plants suitable for various soils.

— **CEREALS IN INDIA.**—Some experiments have been made at the Cawnpore Experimental Farm during 1879-80 on the cultivation of imported English and American Wheats and Barleys. The result seems to point to the conclusion that the time available for the growth of cereals in India is too short to allow of English and American varieties being grown with success, unless possibly the seed is sown in September and runs a risk of being damaged by excessive heat. Experimental sowings were made of three kinds of English and three kinds of American Wheat, as well as of three kinds of Barley. All nine sowings were complete failures. The seeds in most cases germinated freely, and the plants spread out into stools in a manner very different to the habit of country Wheat. But all crops grow extremely slowly, and were still green when native Wheat had finished ripening. In consequence the hot winds of March completely shrivelled up whatever grain had been formed, and no crop worth the name was gathered.—(*Nature*.)

— **WORK FOR WOMEN.**—There is nothing connected with poultry raising, whether for exhibition or for market, that a woman cannot do better than most men, and I would advise all women who from choice or necessity desire to enter the ranks of the producers, and who possess the facilities for poultry raising, to turn their attention to this agreeable pursuit. Mrs. Harrison has warned women not to expect to find a "bonanza" in bee-keeping, and I can assure them that poultry keeping is no "royal road to wealth," but I know that any woman who possesses a fair share of energy and brains, and who can devote a part of her time to the work, can make it fairly remunerative. Will farmers and farmers' wives think of what I have said? and if they will put their thoughts into words for the benefit of our readers so much the better.—FANNY FIELD (in *Prairie Farmer*).

— **BIRMINGHAM AGRICULTURAL EXHIBITION SOCIETY—PRESENTATION TO MR. LYTHALL.**—At the last meeting of the Council of this Society, held at the Queen's Hotel, a conversation took place with reference to the necessity of postponing the Shorthorn Show, which had been fixed for March 9th and 10th, on account of the prevalence of foot-and-mouth disease in the country. Ultimately a resolution was passed, on the motion of the Chairman, seconded by Mr. Holliday, postponing the Show till April 27th and 28th. The Council fixed the Cattle Show for November 26th, 28th, 29th, 30th, and December 1st. The Chairman, on behalf of the Council, presented Mr. Lythall, in recognition of his services as Secretary for a period of twenty-one years, with a richly chased and engraved "antique" pattern silver tea and coffee service; silver-mounted oak coffee tray, with shield and ebony handles, with pierced decoration; a richly ornamented silver biscuit box, a handsome timepiece, and a pair of bronze vases to correspond. The articles, which were supplied by Messrs. Mapplebeck & Lowe, bore the following inscription:—"Presented by the Birmingham Agricultural Exhibition Society to

Mr. J. B. Lythall, in recognition of his valuable services as Secretary for a period of twenty-one years. January, 1881." In making the presentation, the Chairman said it would be in the recollection of the Council that in January last a sub-committee recommended that Mr. Lythall's salary be increased by £100 per annum, and that in consideration of his twenty-one years' service the sum of £100 should be appropriated for the purchase of a piece of plate. The recommendations of the sub-committee were adopted by the Council. Mr. Lythall, instead of selecting one piece of plate, selected a number of articles of a useful as well as of an ornamental character. He thought Mr. Lythall had exercised great discretion in the selection he had made, and, on behalf of the Council, he had very great pleasure in making the presentation to him. The presentation was not solicited on Mr. Lythall's part; it emanated entirely from the Council itself. Mr. Lythall, in returning thanks, said it was particularly gratifying to him to find that his endeavours to perform his duties during a period of twenty-one years had met with their approval. He took the opportunity of thanking those gentlemen who had acted as stewards and taken an active part in the management of the shows for the kind assistance and support which they had given him during the whole of that period. For the very handsome present which the Council had given him he returned his most sincere thanks, and he assured them it would be highly esteemed by himself and his family.

## FOWLS EATING FEATHERS.

I READ with great interest Col. Taylor's "Poultry Experiences" on page 122. I was exceedingly pleased to see that he alluded to that pernicious habit—feather-eating, and I have no doubt, like myself, many readers of your esteemed Journal will feel grateful to your correspondent for the remedy he has recommended. I have been perplexed with my fowls for the last two years owing to their feather-eating propensities. I have been trying the flowers of sulphur, but I am at a loss to know how much to use. I have thirteen fowls; would two or three tablespoonfuls be too much for the above number? and should it be given on successive days, say once a day, or at intervals? I should feel greatly obliged if Col. Taylor would oblige me with the desired information. I am also at a loss to know what induces fowls to eat their feathers. I am disposed to think that feather-eating might be caused by a deficiency of grubs and insects. Three years ago I lived in the neighbourhood of London, and I had a quantity of fowls in confinement, and they never took to feather-eating. I had facilities of obtaining quantities of cheap meat, and I used to give them a little of this every day; here I do not possess those advantages. I think a little meat daily might prevent feather-eating. My fowls acquired the bad habit when they were confined in a very small house and run. Twelve months ago I had a larger house and run constructed; at present the fowls look much better, but several of them have just commenced the bad habit again. I don't think it affects their laying properties, but they look miserable. The opinion of some of your able correspondents on the above subject would be very acceptable.—JOHN MELVILLE, *Great Tew Park, Enstone*.

## POULTRY KEEPING DOES PAY.

I THINK the above has been very clearly proved by many of your correspondents, and I feel assured that if it pays to keep any sort or breed of fowl for their eggs and table qualities it will pay much better to keep a "pure breed," so that you can sell the eggs for sitting and the chickens you rear at a good if not at a fancy price. I enclose you a statement of my poultry account for the past year, and I may add that my accommodation is very limited—in fact, all my birds are wired in, and only have a little run; but I give them plenty of good food and a hot meal of scraps boiled together and mixed with barleymeal every day, in which I put occasionally a little cayenne pepper or flowers of sulphur. I also throw in all the garden refuse, which they are very fond of picking over, and when it begins to decay I turn it out and turn up the soil with a fork every few weeks. By this means I have kept all my fowls in good health, and made a very good profit.

I keep Golden-spangled Hamburgs, and I have found them

strong, healthy, and to bear confinement as well as any breed I know. They are continual layers, and do not get broody. I would advise everyone who keeps fowls to keep young ones, as many people keep the same fowls year after year instead of rearing chickens and killing off the old hens. The consequence is they get very few eggs, and that is why they do not pay.

I am sure we have used as many eggs all the year as we wanted, and they have cost me nothing, in addition to the very handsome profit which is stated below.

## POULTRY ACCOUNT FOR 1880.

Dr.	£ s. d.	Cr.	£ s. d.
January 1st, 1880.	3 16 3	Jan. 1st to Dec. 31st.	
25 fowls of sorts .....	1 4 6	Number of eggs laid, 1620

## POULTRY NOTES.

**THE POULTRY CLUB.**—To-day will meet for the first time the new and enlarged Committee of the Poultry Club. There seems a general expectation that the Club is from now to take, so to speak, a fresh departure, and that the sphere of its influence will be enlarged.

**THE DORKING FOWL.**—An interesting controversy has been going on in one of our contemporaries upon our old English friend the Dorking fowl. The chief points in it seem to be the question whether the modern Dorking is as a table fowl equal or superior to the Dorking of our grandfathers, and also what "points" are really essential to the purity of the breed, and what are the merely arbitrary creations of the fancy. We shall be glad of the opinions of our readers experienced in the breed.

**REARING CHICKENS WITHOUT WATER.**—From time to time many practical poultry breeders have given their opinion that chickens in their early days thrive better, and are less subject to diarrhoea and other maladies of chickenhood, without water than with it. We have always consulted Nature much in our treatment of all live stock, and so have been inclined to disagree with this system. During the last fortnight, however, we have given it a trial, and are determined to pursue it through the early part of the season. Of course, when the weather becomes really hot water must be requisite for the comfort of all gallinaeous birds, but at present we find that the milk from a good feed of bread and milk once a day is quite enough for our young broods to drink.

**PEKIN DUCKS.**—We have heard very opposite expressions of opinion as to the merits of Pekin Ducks as layers; it may not be out of place, therefore, to give the result of our experience. In moderate confinement we find them excellent layers; on a large piece of water at complete liberty very poor ones.

**CROSSING POULTRY.**—The result of crossing different breeds or different subvarieties of poultry is always interesting. An experimenter in Polish crosses last year mated a white-crested Black Polish cock with two Silver Polish hens. Curiously enough the whole of the produce are pullets, heavily bearded and pure black, some with a very few white feathers in their crest. How far may the original Crèves be indebted to some such cross?—C.

## PARIS SHOW.

THE annual Exhibition of live and dead fowls, which is held in connection with the show of fat beasts, seeds, cereals, &c., was opened to the public on Saturday last. It is under the management of the Minister of Agriculture and Commerce, and is in many respects very different from similar shows in this country. Fanciers of poultry are almost unknown in France, and the most of the exhibitors are dealers. The prizes are offered by the Government, and no entry fee is charged; the giving of a simple notice as to the number of pens they require being all that is necessary on the part of exhibitors. As a natural consequence of this the quality of the exhibits is in some cases very poor, the dealers appearing to treat the Show as much as a market for the purpose of getting rid of their superfluous stock as a contest for prizes.

The ideas of the Judges upon what are known as fancy points over

here seem to be in most cases rather unsettled; and the fact that several exhibitors showed two cocks in one pen, and that the number of hens in each pen varied from three to six or eight, must have rendered the task of the Judges by no means an easy one.

The French breeds were of course most numerous represented, there being no less than 531 in the sections devoted to them. The classification as regards the foreign birds was by no means what one would desire, and the entries in this section numbered only about 400.

Turkeys, Geese, and Ducks were rather under 300 in number, while Pigeons had 470 entries. Dead fowl classes were on the whole of great excellence, and far superior to anything of the kind we see over here. They had 233 entries.

The live poultry classes opened with *Crève-Cœurs*, there being fifty-five entries in the cock class, and as many in that for hens. Considering the enormous number of birds thus brought together the quality in some points, such as size and shape, was better than could have been expected, but such fancy points as crests, comb, and muffling were sadly defective. This section has the largest amount in prizes offered to it, there being five in each class. Both the firsts went to M. Jean Farcy. The winning cockerel was of good size, but much too long in leg for our taste; the hens were perhaps the most even lot in the class. Other prizes went to MM. Lemoine, Bouchereaux, Breschet, and Voisin. M. Aillerot showed some white birds which, however, were so dirty that it was hard to be certain whether the colour was pure or not. In *Houdans*, which numbered in the two classes 182 entries, the two first prizes and the *Prix d'Honneur* went to MM. Ronillier and Arnoult for a cockerel of no great merit, and a fairly good pen of hens. It was to these latter that the much-coveted chief prize was awarded. The same remarks which we made above as to the *Crève-Cœurs* apply equally to the *Houdans*, with the exception that the general quality of the exhibits was not so good in the latter classes as in the former. We may note that the prevailing colour, especially of the hens, was much lighter than that which is most fashionable over here, thus indicating the probability of a cross with the *Crève-Cœur* having been resorted to here to gain the fashionable dark colour. There were only three prizes offered in each class, and the remaining prizewinners were MM. Lemoine, Giraud, Voiteiller, and Pointelet. We can remember to have seen in England (as well in regard to size and shape as to fancy points) many finer birds both in the *Crève* and *Houdan* classes than any exhibited at the Paris Show.

Next on the list came the *La Flèche* with 130 entries. The general quality here struck us as being better compared with that of birds shown in England than in the preceding classes. This may probably be on account of the delicacy which these birds develop in the English climate having prevented their being largely cultivated here. Both first prizes went to M. Farcy, who also gained two out of the remaining four prizes, the other two going to MM. Lasseron and d'Imbleval. The hardness of plumage of these birds makes them look smaller in the show pen than the *Crèves* or *Houdans*, but when plucked for table they are really the largest of the three breeds.

The remaining French breeds to which separate classes were allotted were the *Race du Mans* and *Races de la Bresse*. The former of these seems to have its points as regards comb, &c., rather unsettled, but the prizes were both awarded to rose-combed birds. All the exhibits, while varying greatly as to comb, were uniformly black in colour. They suggested a cross between *La Flèche* and Black Hamburgs as the origin of the variety, and the result is a somewhat larger bird more upright in carriage than the Black Hamburg, but otherwise very similar to that variety. As the laying qualities of the breed are very highly spoken of, we presume it is for this that they are honoured with separate classes. The prizes for this class went to MM. Voiteiller and Loyau.

The *La Bresse*, as exhibited, appear to be of three kinds, all single-combed. The first black birds, very much of the type of the *Minorca*, but not so large as the best specimens of that breed. To this variety the two first prizes were awarded, the exhibitor in both cases being M. Maurice. The second variety simply differs from the first in being white in colour, while the third has a white ground colour poorly spangled with black in a manner suggestive of a very bad Spangled Hamburg. To this last variety the two seconds went, the exhibitors being M. Farcy and M. Vallois.

The next two classes were for any other French variety, and there were four prizes in each class, with fifty-two entries. By far the greater number of these were *Courtes Pattes*. These birds were all black in colour, and some of them were extremely short in leg. They would appear to be now quite as well fixed as a distinct variety as the better known French breeds. The first-prize cockerel, which was exhibited by M. Farcy, was of this breed, and of great merit, being of fine size, very short in leg, long in body, and in brilliant condition, while he was the only specimen of the breed that had any claim to be described as white in earlobe. Judging from the number of birds with red earlobes exhibited at Paris, we think the English judges are wrong in at present attaching too much importance to this point. In the class for hens second went to *Courtes Pattes*, belonging to the same owner. There were three in the pen, all short in leg and good in size. One of them was in brilliant condition and specially good in all points, but the other two showed traces of feathers on their legs, which we consider a great fault. The second prize in the cock class and the first in the hens were awarded to birds exhibited by

M. Vallois described as *Barbezieu*, which, however, we could not distinguish from the Black La Bresse. Third in cocks went to Courtes Pattes of M. Lemoine. Fourth in cocks and third in hens went to a breed described as *De Mantes*, shown by M. Voiteiller, which were very like Houdans with single combs, no crests, and only four toes. The legs of these birds varied in colour, and some of them showed traces of feathers, which seemed to us to indicate that they had been produced by a cross between the Houdan and the single-combed French Brahma Pootra. Several pens were exhibited of a fairly uniform type, so we presume that the variety has been kept by this exhibitor for some time. Other birds shown in the Variety class were *Breton*, which were very much like the *De Mantes*, except that the cock showed one or two white feathers, and the hens were speckled with white. *Picard*, resembling small Scotch Greys, rather long in leg; *Caussade* and *Gatinais*, none of which were distinguishable from the Black La Bresse.

The foreign breeds do not call for any lengthy notice. Buff *Cochins* were only very moderate in quality, and the same remark applies to the other variety of *Cochins*. In this latter class some fairly good Cuckoos were shown by M. Voiteiller.

The *Brahma Pootras* were, with one or two exceptions, single-comb birds of the Light variety, rather darker in saddle and hackle than we are accustomed to on this side of the water. The single comb, however, does not seem to be absolutely insisted on, as in the first-prize pen of hens shown by M. Breschet there was one pea-combed pullet. As all the birds exhibited by M. Voiteiller had pea combs we may presume that this gentleman is a convert to the English view on this point.

In *Dorkings* the prizes went in all cases to Silver Greys, which were so far superior to the general run of the class as to lead us to believe that they were imported birds. The winners were MM. Breschet, Lemoine, and Vallois.

*Spanish* were very inferior lots indeed, the cocks being cauliflower-faced, and the hens very poor in face.

*Polish* were a very promiscuous lot, the best exhibits appearing to us to be those of M. Lemoine. The first in the cock class was awarded to a pair of rather poor Silvers, exhibited by M. Breschet. We noticed a rather curious Frizzled Chamois Polish cock in this class.

The variety classes for large breeds and Bantams respectively contained nothing very remarkable, while the judging showed rather an ignorance of the points of the various breeds. M. Lemoine, who seems to be more like an English fancier than any other French exhibitor, showed some fair Hamburgs, Langshans, and Leghorns, and the same breeds were also exhibited by M. Voiteiller.

Geese were a fairly good collection, and Turkeys were considerably above the average of the other poultry classes.

The Pigeons were a very miscellaneous assortment, the best filled classes being those for table purposes. Many of these birds were of remarkable size. Amongst the Fantails we noticed some birds of rather unusual colour, which might be worth the attention of our English fanciers.

In Dead Fowl the first classes were for *La Flèche*. Some wonderful birds were exhibited, the first prize going to M. Choquet for a large pair of birds, one of which, however, seemed to us to be rather muscular in his wings. Mme. Aillerot took prizes both in the classes for capons and poulards with splendid specimens, which we were informed weighed when prepared for table from 9 to 10 lbs. each. As we have before remarked, the *La Flèche* were the best dead poultry classes, the other sections not being on the average up to this breed. In the Dead Fowl variety class first went to Mme. Aillerot for a fine pair of *Du Mans*, which looked better on the table than in the pen.

Turkeys were well represented, as also were Geese, the second prize being of the Race de la Sarthe, apparently a cross between the White and Grey varieties, and weighing 16 lbs. each.

The incubators and rearing appliances made a show in themselves; but of these we must reserve notice.

### KEITH SHOW.

THIS old-established and popular Show was held on Thursday and Friday, 17th and 18th inst., and notwithstanding the very severe winter was quite up to the average both in numbers and quality. Mr. Anderson of Nairn judged the whole Show, and his awards, as usual, gave general satisfaction.

**DORKINGS.**—*Coloured* (thirteen) were an exceedingly good class. First, two cups and special (Cran), the cock the Aberdeen winner, a grand two-year-old bird in good form, the hen good with white feet. Second (Auchinachie) a cockerel and pullet, good in shape and comb, with fine white feet; v.h.c., Beaton; h.c., Barclay; c., Cran. *Silver Greys* (fifteen) were another very fine class. Being favourites in this quarter they always produce good entries. They included the winners at the principal shows in the north. First, cup and two specials (Cran), an old bird of true Dorking shape, with a magnificent head. Second (Annand) the cockerel a beautiful large Silver with a very good pullet; v.h.c., Cran; h.c., Annand; c., Robertson.

**SPANISH** (ten).—First (Logie) a really good pair in all points. Second (George) also very good; v.h.c., George; h.c., Simpson; c., Reid.

**BRAHMAS** (sixteen) were a good all-round class of Darks.—First (Suter) cup and special, old birds, cock very good, with a much better hen. Second (Suter) a good cockerel and pullet; v.h.c., Bennet; h.c., Forbes; c., Cran.

**HAMBURGS.**—*Pencilled* (thirteen) were one of the best features in the Show. The competition in this class was keen. First (Mearns) grand well-marked birds, look like the Aberdeen winners. Second (Thomson) rather indistinct in marking; v.h.c., Hay; h.c. (Cunningham) we preferred to second. *Spangled* (fifteen).—First (Mantach) well-marked birds, good in comb and lobes. Second

(Mearns) heavy in comb; v.h.c. (Campbell) we thought might have stood first; h.c., Campbell; c., Smith.

**COCHINS** (fourteen) were a fair class. First (Mantach) fair Partridge. Second (Fraser) Whites, beautiful in colour but rather small; v.h.c. (Mantach) Buff, the Aberdeen winner; h.c., Carr; c., Bunn.

**GAME.**—*Pile or Duckwing* only produced two entries. First (Grant) very promising Piles. *Black or Brown Reds* (nine).—First (Allan) Brown Red, the Elgin winner in grand condition. Second (Allan) Brown Red, far behind first; v.h.c., McRae, and h.c. (Davidson) Black Reds.

**GAME BANTAMS.**—*Any variety* (five).—First (Mantach) a smart pair of Piles. Second (Weir); v.h.c. (Esslemont) might, we thought, have been first; h.c., Simpson.

**LANGSHANS** (twenty-six) was the strongest class in Show. First-and-cup (Slcigh), the Aberdeen winner, large bird, bad eyes, and feet rather rough. Second (Auchinachie) a very nice pair, well shown; we would have preferred them to first; v.h.c. (Pirie) very good old birds; h.c., Cran; c., Davidson. *Any Other Pure Breed* (eight).—First (Dashar) very good Polish. Second (Cran), good Leghorns; v.h.c., Black (Polish); h.c., Cran (Scotch Greys).

**DUCKS.**—*Aylesbury* (twenty-one), the best lot we have seen this season. First (Reid) the Elgin winners, really a fine pair. Second (Longmore) a very promising young pair; v.h.c., Taylor, also good, with fine bills; h.c., Brown; c., Longmore. *Any Other Pure Breed* (twenty-one) were another good class, principally Rouens. First (Cran) Pekins, Elgin winners, large, and fine shape. Second (Simpson) Rouens. Third (McDonald); v.h.c., Simpson; h.c. (Gordon) the Elgin winners; c., Thomson.

**GEESE** (six).—First (Gordon) a very large and fine pair. Second (Grant) smaller, but also good; v.h.c., Smith.

**TURKEYS** (eleven) were a fine class. First (Suter) Norfolk; second (Stephen) Cambridge; third (McDonald) Norfolk; v.h.c., Gordon (Norfolk); h.c., Cran (Cambridge).

**COLLECTION OF PIGEONS.**—First (Smith) a grand collection of twelve pairs of different varieties. Second (Longmore); v.h.c., Milne; h.c., Mearns.

### OUR LETTER BOX.

**Market or Eggs (H. T.).**—The price named by "W.C." was for fresh eggs. In the neighbourhood of large towns there is generally no difficulty in getting a remunerative price for these. In the country it is difficult, and we can only suggest an advertisement in the local press of the most accessible town.

**Chickens Weak on Legs (Idem).**—Allow the chicks as much liberty as you can. Give them a sod to pick and scratch at on wet days. Keep plenty of dry earth, ashes, or sand under them, and do not let them run on bare flags or boards. A little stimulating food, such as meat scraps and bread and ale, may also be given with advantage.

**Roup in Pigeons (T. S.).**—When birds are affected with this disease remove them into a warmer place, feed them extra well, adding hempseed, and giving a few peppercorns every other morning. It is kind and also reasonable to cleanse the poor bird's mouth and eyes with warm water, using a very small piece of sponge. Pigeon fanciers differ as to whether or not roup is contagious. We recommend separation in order to be on the safe side.

**Salt for Pastures (J. V.).**—Our late recommendation as to the use of salt upon grass land had special reference to the destruction of the fluke egg or entozoa. We do not recommend the application of salt as manure for pastures, except they consist of very dry sandy, gravel, or limestone subsoil, but a dressing of fishery salt or kainit may answer of 3 or 4 cwt. per acre if the pasture is situated away from the coast, as there is usually a sufficiency of saline particles floating in the air within a few miles of the sea. "The manuring and improvement of pastures" will form a special subject in an early issue of this Journal.

**Prickly Comfrey (Aylesmere).**—You will find full information upon the cultivation, extent of crop, &c., in an article which appeared in this Journal on the 10th of June last. If you do not possess the number it can be obtained at this office for 3½d. in postage stamps. The plants of Prickly Comfrey can be obtained of nearly all seedsmen and nurserymen. There is one question worth consideration as to the value of a crop of Prickly Comfrey compared with a crop like Lucerne; the former requiring tillage, &c.; the latter yielding three good cuttings with manure only applied.

### REMARKS.

13th.—Fair, but generally overcast; cold wind.

14th.—Fair till 11 A.M., slight rain rest of the day.

15th.—Rain in morning; fair after 1 P.M.

16th.—Foggy morning; fair in middle of day with gleams of sunshine; bright starlight evening.

17th.—Foggy morning; misty damp day.

18th.—Foggy morning; fair but overcast during the day.

19th.—Fair and calm, but damp.

A gloomy overcast week, in no way remarkable.—G. J. SYMONS.

### DRUMLANRIG IN WINTER.

**I**D WINTER with the snow half a foot deep, and the thermometer indicating a temperature near zero, was hardly the time when many would think of travelling a distance on an expedition of pleasure, as under these circumstances in the majority of gardens there would be little of interest visible; but Drumlanrig is at least one exception to this rule, as it is to many others in gardening.

From the small station of Thornhill the Castle can be seen at a distance of four miles, and the fine woods and undulating ground with which it is so picturesquely surrounded can be seen far beyond. The village of Thornhill appears, as it did twenty years ago, to be still in its infancy, but the manner in which its two or three short streets are lined on each side with finely-shaped Lime and other trees shows the improvement which might be wrought in many other towns and villages. Not far from here, and about three miles from the Castle, we enter the main road, and were much pleased with the appearance of a number of fine specimens of the Weeping Birch amongst other choice trees near the drive side. They were draped with crystals of hoar frost, and as the rays of the morning sun shone on them they appeared quite dazzling. We doubt if ever they looked so beautiful in summer; but be this as it may, they are certainly trees which would give satisfaction at all times, and are well worthy of being widely cultivated. The garden is reached about one mile on the station side of the Castle, and although it is not hidden it lies very low, and must be subject to both early and late spring frosts.

All branches of gardening are extensively and well carried out at Drumlanrig. Everything worth growing is grown in quantity. The small flower garden which adjoins the kitchen garden contains many beds of Carnations, Phloxes, and other flowers. There is also in this garden a fine herbaceous border some 600 feet in length by 20 in width. Surely a patch like this, planted as it is with the best selected hardy plants and flowers, ought to show at a glance what can be done with such plants, and it does. It was simply as naked and bare, so far as flowers were concerned, as any spot in the garden. I felt sorry for those who speculate in hardy plants under the impression that they will afford them a never-ending supply of flowers. There is no denying the fact that they have the best of chances and attention here, and the result is not encouraging.

Further than showing fine open quarters for summer vegetable culture, the kitchen garden contained nothing of note.

On the site of the bottom or south wall, where we remember a number of Peach, Apricot, and other fruit trees bearing about three fruits to every 10 square yards once every half dozen years, there now stands the finest orchard house in the kingdom. It is span-roofed, 600 feet long, 24 feet wide, and 18 feet in height. It is most substantially built, well heated, and although only planted three years ago with Peach, Apricot, Plum, Pear, and other trees, they are now in a full bearing condition, their strength and training showing the care devoted to them. In precarious climates or unprosperous seasons a house like this must be profitable in the extreme. That there are not more of the kind is surprising, especially as this has been such a success. We need not describe in detail all the other glass houses, but may mention that those constructed during the last ten years are unsurpassed for convenience and finish. The vineries are of little interest at present, as Grapes are only grown in quantity for autumn supply; and a supply there is sure to be, as the rods are extremely strong. The numerous Pine plants are also extraordinary examples of high culture. I have never seen their equals. The fruit of those first starting will be worth going a long way to see.

Stove plants are numerous and in splendid condition. The short days and cold weather does not appear to have any injurious influence on them there. The Crotons, Dracænas, Aloecasias, and other fine-foliaged plants were noteworthy for their healthy foliage, their high colours, and the small pots they were growing in. Most of the pots employed in the stoves, Orchid and other houses, are glazed outside. This gives them a very clean ornamental appearance, and they never need washing. Before leaving the stove I must not omit to mention several seedling Crotons which Mr. Thomson has been fortunate enough to raise. They are more ornamental than many now in commerce. One in particular I thought the most showy Croton I had seen. It has very broad leaves of the brightest canary colour, a good habit, and has a distinct effect even amongst the best of its genus. Pitcher Plants, including Sarracenias, are well cultivated at Drumlanrig. The Nepenthes are acknowledged to be the finest in the country. They are mostly grown in living sphagnum moss in small baskets and pots, the size and colour of the leaves and the magnitude of the pitchers being surprising. Their propagation is sometimes a doubtful operation to many. Here they root freely in sawdust and plunged in strong bottom heat. Sawdust is an important material in the garden at Drumlanrig. It is largely used for plunging, for propagating, and as a restorative agent. Whenever a rare Orchid or other plant is deprived of its roots or is in a sickly condition it is washed clean and potted in sawdust, and rarely does this fail to start them into fresh vigorous growth.

Calanthes are grown largely. They were being potted at the time of my visit, and the pseudo-bulbs promised well for flowering. Hitherto they have produced many spikes 4 feet long to each pot, and for cutting for vase decoration in September and October they have no equals.

We now come to the Orchids, of which Drumlanrig may justly be credited with one of the finest and most healthy collections in the country. For health and cleanness they leave nothing to be desired. Several large houses are devoted to them, both "cool" and "hot." In the cool house the Odontoglossums are splendid. Some 250 fine plants of *O. Alexandræ* and *O. Pescatorei* form the stock of these useful and valuable

Orchids. *Cypripediums* in quantity and of the best kinds, *Masdevallias* and *Pleiones*, all do remarkably in this house. A *Vanda* which has been undergoing cool treatment here for the last two years is as healthy as those in warmer quarters. Into this house Mr. Thomson told us air is admitted through 4-inch pipes placed at intervals in the front wall, and the gravel on which the pots stand is placed in zinc trays, which are kept constantly filled with water in hot weather. In the warmer houses *Vandas*, *Dendrobiums*, *Lælias*, *Phalænopses*, *Aerides*, *Cattleyas*, *Cœlogynes*, and other Orchids that are worth growing are in a most luxuriant condition. The *Vandas* are growing in finely made oak crates about a yard square and as much in depth. These contain from three to six plants each; many of them are 4 feet in height and well furnished with foliage. Plants of *Phalænopsis amabilis* are in hanging baskets, and have long spikes of bloom and buds in profusion. In one of the Orchid houses there are a number of plants of *Anthurium Scherzerianum*, which for size and health are the finest specimens I have seen. The number of spathes these will produce will be enormous, and we may depend they are the best varieties, as no plant would ever be grown to a large size at Drumlanrig which was in the slightest way inferior in either form or colour.

On the back wall of one of the lean-to Pine houses *Bougainvillea spectabilis* receives that attention which it seldom gets but highly merits. Four plants are planted out in a narrow bed, and they are trained fan-shaped, like Peach trees. The branches are very strong, and twice a year all the side shoots are cut off them, when they afterwards emit a profusion of young shoots, each of which produces long racemes of their beautiful pink bracts, which are much valued. The cool greenhouses contain large quantities of the hardier Palms, *Heaths*, and one of the most promising collections of young specimen *Azaleas* I have ever had the pleasure of seeing. *Camellias*, too, are in grand health, and bloom profusely from September onwards. By starting them into growth early and growing them on freely there is no difficulty in having them in bloom so early as September, and this is certainly worth knowing and practising by those who have many cut flowers to supply in the autumn months.

About one mile from the kitchen garden and chief glass houses is the flower garden. Some hundreds of thousands of bedding plants are employed here in summer; but of course in winter there is nothing to be seen in this way, only the extent of ground gives an idea of the wonderful display of exquisitely arranged colours that must be seen here at the height of the season. About 60 acres are devoted to flower garden and shrubbery. Terrace after terrace, with level spaces between, rise until the level of the Castle is reached, and in looking down from this elevation one of the finest views in the country is obtained. The flower garden lies below; plateau after plateau, with dark Yews and other trees intervening, comes into sight in rapid succession, while on the other side of the river an elevated ridge of forest trees forms an effective background. Eastward from this are remarkable harmony of hill, dell, and stream is visible for a distance of sixteen miles or more. I have heard lords, ladies, squires, nurserymen, gardeners, and travellers of many nations say the like of Drumlanrig they never saw, and with all I thoroughly agree.—PARAGON.

#### NOTES FROM MY GARDEN IN 1880.

##### GLADIOLI.

THERE is one advantage in growing many plants—that if failure takes place in some there are others which compensate for it. All the eggs are not in one basket. Thus, although I had to complain of the orange fungus amongst my *Roses* and of the woolly aphid amongst my *Auriculas*, I had a very successful season with another favourite flower, the *Gladiolus*; yet it, too, is one of those which in other seasons has caused me much trouble, and which still puzzles me exceedingly.

My culture of the *Gladiolus* is very limited in extent, and I believe our great grower Mr. Kelway was considerably amused and not a little surprised when he saw how small it was. "Well, I have seen him show some fine spikes, and do you mean to say that he cut them from these beds?" was his somewhat incredulous query; and I can well understand how the man who grows his

twenty acres must have regarded the two or three small beds that I manage to cultivate. I have now grown the *Gladiolus* for twenty years. Some seasons I have been in despair and ready to give them up altogether, at other times so captivated with them that I have determined to run all risks and go on with their culture; and the strange thing is that I have never been able to give any reason why one season should be favourable and another unfavourable. The mode of treatment varies but little, the character of the soil remains the same, and yet the difference is very great. In one season I see a vast number of the corms dying and the good trusses comparatively few; in another the gaps limited in number and the blooms excellent. I do not see that the character of the season makes much difference. They like moisture, but 1879 was too much for them; but in a very dry season they do not flourish. Fine autumns which tend to ripen the corms are in their favour, but we did not certainly have a fine autumn in 1879, although it was, of course, the corms saved then that gave me the good bloom of 1880. My stock generally consists of corms of my own saving. A few I obtain from France and a few from Mr. Kelway. I do not see much difference as to the losses, which occur pretty impartially in all three, although I think on the whole I have better blooms from the corms raised in France than from those saved by myself; I mean, of course, the same varieties.

Last year I had two of my beds in a part of my garden where I never had them before, and these certainly were the best. Of course it will be said it was new ground and the soil was not sick with them; but the year before, when I had so many failures, they were grown in beds where I had not had any for eleven years; and as I have said, one of the most successful growers I ever knew grew his for seven years in the same soil, and I believe, had he lived, would still have grown them in it. The soil, too, was very much stiffer than I thought would have suited them. So here again I was puzzled, as I know most growers consider a friable soil best suited for them, and that at Fontainebleau is of this character. Then, again, some of the finest blooms that I had this season were from some scattered corms which must have been in the ground eight or nine years, as they came up amongst my *Roses*, and must have been the produce of spawn that had remained in the ground all that time. One thing has certainly been impressed on my mind more and more, and that is that deep planting is the best. I shall never plant at any shallower depth than 6 inches, and I am not sure that even more would not be desirable. I believe, too, that a good heavy mulching of manure is very essential to their well-doing, and that it ought to be applied somewhat early so as to throw vigour into the stems; for although they do not like to have fresh manure in contact with them, they seem to delight in the moisture that reaches them from it.

I cannot too strongly advise those who wish to cultivate this very beautiful flower to be very careful over the spawn (as the small corms are called), which in some varieties are found in large numbers clustering round, while in others they are comparatively scarce, and in some varieties, such as *Adolphe Brongniart*, are very rarely found. The plan I have of late years adopted is to take them off at the time of lifting the corms, store them away in paper bags, and then in the spring pot them, first of all taking off the outer hard skin. A number are placed in a pot, and put in a cold frame. When they have started and the pots are tolerably well filled with roots they are turned out into the open ground, and make by the end of the season very fairly sized corms. These in a year or two will give good spikes of bloom. It is all very well to talk about depending on seedlings; but as in all other flowers the really good ones obtained are few, and although there is much pleasure in raising new varieties, there is ever the danger of thinking too much of one's own children. A grower like Mr. Kelway, who reckons his seedlings by hundreds of thousands, and whose long experience enables him to decide on the merits of a flower, is in a different position; but for those who only grow a few, while seedling-raising may be a very interesting occupation, it is not well to place dependance on the seedling bed for exhibition purposes.

With regard to new varieties, I think that some of the French sorts of last year are of a very high order of merit. Perhaps the two best were *Baroness Burdett Coutts* and *Archduchess Marie Christine*. The former is a very large flower with a very long spike, rosy lilac in colour with carmine spot on the lower petals, and altogether a very remarkable flower. *Archduchess Marie Christine* is another very beautiful flower for which I obtained a first-class certificate; white ground, flamed with rosy lilac; large well-opened flowers, and a beautifully formed spike. *Flamingo* is a most brilliant scarlet flower with a purple shading in it, somewhat in the style of *Pasquin*; while *Rayon d'Or* is a good accession to our limited class of yellows.

Among the few that I have been enabled to grow of Mr. Kelway's I found the following last season to give me fine blooms—*Marcianus*, a brilliant orange red, with a suffusion of purple and carmine stripes on the lower petals. *Rev. H. H. D'Ombraïn*, cerise; a large and beautifully formed flower, with a clear white throat of great substance. *Claribel*, a pure white, with a violet stripe on the lower divisions. *Earl Russell*, violet shaded with rose, with a dark violet stripe on the lower divisions. *James Kelway*, crimson edged with maroon, with a white line on each petal; good form and stout in substance. *Mrs. D'Ombraïn*, white tinted with lilac rose. *Dr. Woodford*, salmon flaked with carmine, yellow spot on the lower petal; a fine flower. *Egyptian King*, a very remarkable flower, dark maroon in colour, shaded with deep brownish crimson; somewhat in the style of Souchet. *Africain*, a very fine flower. These are, I am aware, but few out of the many remarkable flowers raised by Mr. Kelway; but I have noted here only those which have bloomed in my own garden. There is no more lovely flower for autumn decoration than the Gladiolus, and despite its waywardness one cannot help wishing that we saw it oftener on the exhibition table; but it does not come in until the London season is over, and hence it receives but scant recognition. We may, however, anticipate a good display of it at the Manchester Exhibition, where doubtless Mr. Kelway will come out in great force.—D., *Deal*.

#### THE VEGETABLE SUPPLY.

BEING a grower of vegetables in four counties, and an amateur, not a professional, I send you some experience you may think worth while to insert in your Journal.

I corroborate every word that has been written by the two market gardeners from Cheshire and Liverpool in your number of February 10th. I am perfectly certain, from a knowledge of many parts of England and its rural population, that before farmers are persuaded to turn to market gardening the present generation of mothers must themselves be taught the use of and methods of cooking vegetables, to teach the rising population in turn, the same as the French and other continental nations, and learn what an immense advantage to their households, however poor, it is in a sanitary point of view, as well as having good and nutritious food in the form of soups that all classes of the French consume every day both winter and summer made from Cabbage, Onions, Leeks, Gourds, &c. This I have to teach to almost every English cook I get. When the population learn this desirable art of treating their families daily to a vegetable diet, it will probably pay those that understand vegetable production to go in for it on a larger scale than at present. Owing to the above facts, I am quite positive that in most parts vegetables are at present raised far beyond the requirements of the poorer classes, and hence the bad prices complained of everywhere, and the immense waste of vegetable produce, poor as that produce is generally, in every parish. Farmers are not likely to make profits in present bad seasons where professional and intelligent market gardeners are unable to keep large stocks of Broccoli and Cauliflowers through these winters of severe and variable weather. If "WILTSHIRE RECTOR" and others would carry out this excellent idea of having the cottier population taught the use and cooking of vegetables in every parish of England, we might be sure of a vast decrease of illness, a far more healthy and thrifty people, and then it might pay to increase the growth of vegetables. I think farmers ought to think twice before becoming market gardeners.—SAXORING.

#### ROSES—HARD PRUNING—ORANGE FUNGUS.

AFTER the experience of last season, and the timely warning given by "D., *Deal*," on page 68 of the Journal, I should expect every Rose-grower to be particularly careful when the season for pruning arrives. Those who, like myself, grow only a hundred or two, and who may be held to be less experienced, should especially take note. I did not commit the mistake of sparing the knife last spring. In fact, several who saw my work considered I had gone to the opposite extreme. I pruned many plants down to the surface, even below the surface of the ground, so that when finished some spaces seemed empty. I had, however, the satisfaction in due time of hearing some of these same friends exclaim, "What fine wood you have!" and I did not lose one plant, although they were only protected by a slight covering of leaves. This safeguard I have again employed, and I feel pretty confident that this year with better ripened wood and the removal of every inch of what is injured, my loss will trifling, notwithstanding the intense and protracted frosts we have had.

My plants every year suffer in some degree from the orange

fungus. Rivers in his "Guide" says, "No cure has yet been found for this disease." I have looked for some reply to "D., *Deal*," with regard to this pest, but none has yet appeared. My soil and situation are both considered favourable to the Rose. I have tried picking off the affected leaves, but I soon found it impossible to cope with it in this way. I may say that last year it seemed checked by one or two liberal dustings with flowers of sulphur applied for mildew. I afterwards syringed the plants with a strong solution of soft soap at a rather high temperature. I cannot remember where I saw this recommended. The fungus did not spread to anything like the usual extent, although the dry weather we had is held to be inductive of this special plague, and I shall adopt the same treatment unless some of your readers can recommend a better.

All Gladiolus growers must await with interest "D., *Deal*," notes on his experience with these favourites, and, perhaps, some interchange of opinion as to varieties, &c., may be of value before the planting season has arrived.—A NORTHERN AMATEUR.

#### CUTTING DOWN YOUNG VINES.

YOUR correspondent Mr. Pettigrew has referred to this subject in terms that are sound and reasonable. There are, however, too few employers who are inclined to give their Vines such a chance as is there claimed for them. They generally expect to see the colour of their Grapes the second season. Two or three bunches to a Vine may safely be taken without much injury to the Vines if the following course is adopted:—Bend the rods down and peg them into the soil as shown in the accompanying figure. Rub off all the buds below *b*, except at *a*. Prune the cane back to the very best eyes, if they are half way up the rafters so much the better. Restrict the growth of the side shoots above *b*, so that the

Fig. 36.

prominent canes coming from *a* may have plenty of room. Leave two or three bunches on the supernumerary cane, allowing it to extend to the top of the house, and in the third and fourth years take the main part of the crop off this cane, when it may be cut out altogether. By this plan you can get a better permanent cane, and I think this is best done by only allowing it to extend up the rafters 6 or 8 feet the first year, encouraging a good lateral growth at the base. Restrict it in a similar manner the second and third years, leaving but a limited number of bunches on it till the other rod is cut out, when it will generally be found to be in a good position as a permanent Vine. By pegging the cane into the soil it soon becomes rooted and in a measure self-supporting, and so there is less risk of the Vine being exhausted by bearing fruit the first and second years. It will be understood that all shoots must be kept pinched close on the temporary cane as the other advances up the roof.—R. INGLIS.

CHLOROPHYLL.—Mr. W. Carter contributed the following remarks to a recent issue of *Nature*—If Cress seeds are grown for

a few days in the dark on damp cotton wool, and then, beneath the surface of water, introduced into an inverted glass jar filled with water, they may be exposed to daylight for an indefinite time without chlorophyll being developed. But the plants are not dead; for if, after a few days' exposure, the cotton wool on which they have been grown is cut in two beneath the surface of the water, and one half, with its plants, is restored to the inverted jar of water, while the other is placed under an inverted glass jar containing air only, and then these two jars be exposed to full daylight, the plants beneath the jar containing air rapidly become green, while the others never do so. Light, therefore, cannot always cause the development of chlorophyll in the etiolated leaves of living plants.

#### MARÉCHAL NIEL ROSE ON ITS OWN ROOTS.

I CAN corroborate what has been said in favour of this Rose doing well on its own roots. We have here a plant which was a cutting struck in February, 1879. In April following it was planted in a border 2 feet wide at the foot of the back wall of the greenhouse. The soil used was strong turfy loam and cow manure, four parts of the former to one of the latter, with a free admixture of old lime rubbish; the depth of soil is about 2 feet, and 1 foot of drainage. It commenced growing freely, and was copiously supplied with water at the roots and well syringed. The shoots, several in number, were trained thinly on the wall and under the roof, and last February it produced thirty-five blooms. After blooming it commenced growing freely, making twelve new shoots, which were trained in a downward direction towards the front of the house; the longest shoot made since March last is 25 feet; upon the plant there are now 340 bloom buds, which look healthy and strong. We give the border a good soaking with weak liquid manure about every ten days. Another plant put out in the same border in March last (a cutting in February previous), commenced growing with three shoots, the longest of which is 28 feet; on it there are at the present date 130 bloom buds. In the same border I planted at the same time as the large Maréchal Niel a plant of Gloire de Dijon on the Manetti stock. It made scarcely any progress the first season, growing only about 2 feet. Last March it threw out three shoots from the bottom just above the union. They grew fast and strong. Five other shoots followed from the top of the previous year's growth. The whole plant is now covered with buds from top to bottom, four hundred in number. Several blooms have also been cut during the winter. The above plants have never at any time been troubled with green fly or mildew.—E. MOLYNEUX, *Swanmore Park, Bishops Waltham.*

It was scarcely necessary for "OXONIAN" to explain on page 146 that he had not struck hundreds of Maréchal Niel Roses from cuttings, as had he done so he would not have said in a previous issue "Maréchal Niel, I am certain, will not do well on its own roots." Before "OXONIAN" was so "certain" on the point that he raised, he ought, at least, to have been fortified by experience. I spoke within the mark when I said I had gathered hundreds of blooms of Maréchal Niel from plants struck from cuttings. I have really gathered thousands. One plant or tree yielded an average of four hundred blooms for ten years, and I could name another that has produced twice that number. I have sent plants to many counties in England, to Scotland, Ireland, and even America—or rather I struck them, and they were sent as presents to friends or in exchange for other things—none were sold. Blooms from some of the plants raised from cuttings were sent to the Editors, who stated they had never seen finer. "OXONIAN" appears to doubt the longevity of the Maréchal on its own roots; but when he has had, as I have had, thirty years' experience in Rose culture, he will find that this fine Rose when well established on its own roots will live longer than when worked on either the Briar or Manetti stocks. Worked low on the latter stock the Rose is soon on its own roots, and worked high on the former it swells, forming large protuberances, cankers, and decays. I doubt not that we shall yet have further evidence that the Rose in question will do well on its own roots notwithstanding the strong and unqualified assertion to the contrary.—A ROSARIAN'S GARDENER.

#### PARAFFIN TUBS.

YOUR correspondent Mr. A. Harding will find tubs made from paraffin barrels exceedingly useful for large plants when sawn through the middle, having been previously burnt out, which most effectually destroys all traces of either paraffin or spirit. The operation of burning further assists the wood in resisting the ill

effects of the moist soil as the inside surface becomes charred. It will probably be necessary with his barrel, which has been some time in use for water, to first dry it and place a little paraffin in the bottom, which with a few live coals thrown in will ignite the whole of the inside surface. Some judgment is required in not allowing it to burn too long, but in the case of recently emptied tubs a longer time may be allowed. When it has exhausted the spirit, which may be judged by the cracking of the wood, turn the barrel upside down with a long-handled rake, and the flames are at once extinguished. A good scrubbing renders them sweet and fit for use. A couple of iron handles from the blacksmith made with six screw holes to each are of great assistance in removing them when filled; two or three coats of green paint, and finally one on the hoops of black, renders them fit associates for the newest of pots.—J. W. SILVER, *Farnley Gardens, Otley.*

YOUR correspondent A. Harding requests information as to the mode of preparing paraffin tubs for Tree Ferns, and perhaps the following hints may be of service to him:—I have employed them for the last four years for Ferns, Palms, and fine-foliaged plants, and have found them answer remarkably well. I have the tubs cut in halves, the sharp edges being rounded off with a spoke shave; five holes are then bored about an inch in diameter for drainage, after which I place a few shavings in each half, light them and allow them to burn until the wood is partially charred, when the fire can easily be extinguished by turning the tub upside down. Handles are then screwed on, and three coats of green paint are applied. I thus secure useful plant tubs at a nominal cost. It is doubtful if scalding them would be successful, but no one need be afraid of placing the most tender plants in them after having undergone the above operation.—S. MORTIMER.

[Mr. W. Iggulden also states that he has found the above practice successful.]

#### THE CINERARIA.

THE numerous varieties of this popular flower are supposed to be the offspring by various crosses of *Cineraria cruenta*, *C. lanata*, *C. aurita*, and others, which were introduced into this country from the Canary Islands about the close of the last century. There are no plants amongst the florists' flowers that produce such a variety of colours as the *Cineraria* of almost every shade except yellow, and no plants with which I am acquainted will repay the cultivator better for his trouble than these, for they seldom fail to flower unless by wilful neglect they become infested by aphides, which immediately attack the sickly plant. Amongst the varieties usually cultivated the double forms introduced a few years ago are worthy of special mention. They are very effective, but the flowers are not so large and striking as the single ones.

*Cinerarias* are easily raised either by seed or by offsets: the latter is the mode adopted to preserve good varieties. As soon as the plants have flowered remove them from the conservatory or greenhouse, cut down the old flowerstems, and place the pots in a cold frame, giving water sparingly until growth commences. When several leaves are formed take the offsets carefully off with a sharp knife, and if possible with a portion of the rootlets attached; place them in small pots and grow the plants in a cold frame, keeping them close and shaded from the light for a fortnight, and from bright sunshine for another week. By this time they will be well rooted, and will require a shift into pots a size larger.

The easiest way of raising a batch of plants, and the one generally adopted, is by sowing seed towards the end of April. By procuring seeds of some well-known strain a large proportion of the seedlings may be relied upon to produce good blooms. The following is the method I pursue:—Take a clean flower pot 6 inches in diameter, and fill it three parts full with potsherds; then place a little moss or a few leaves over them to prevent the drainage from becoming choked, fill up the pot with some fine light soil, press it down lightly, and make the surface smooth; sow the seed, and cover lightly with a little fine soil, and give a little water through a fine rose; afterwards lay a piece of glass over the pot, and place it in a frame or greenhouse. The seedlings will appear in about seven or eight days after sowing. As soon as they have three leaves prick them out into shallow seed pans in a somewhat richer soil; they may then remain in these seed pans till they have produced more leaves and fresh roots. Pot them into 3-inch pots, shade for a few days, and when the roots reach the sides repot the plants in the same manner as the offsets. Prepare a compost in the following manner, mixing in a moderately dry state:—Turfy loam from an upland pasture, two parts; decayed leaves, one part; manure from an old Mushroom bed, one part; and a small addition of coarse river sand.

The whole should be well chopped with the spade and carefully mixed before using, but not riddled. Preparing the drainage of the pots is of the greatest importance, as Cinerarias require at all times an abundant supply of water, and neglect of this often leads to disastrous results. Have a sufficient number of 6-inch pots well washed and dried; have also a quantity of potsherds in two sizes—one about the size of walnuts for the bottom of the pots, the other smaller to cover them. There should be at least  $1\frac{1}{2}$  inch depth of crocks covered with a little dry moss or leaves to prevent the soil mixing with the drainage; then proceed with the operation of potting by placing a handful of soil on the crocks sufficient to keep the plant level with the rim of the pot, set the plant in the centre, and fill round it with the compost, pressing it gently down; be careful not to break the leaves, as they are very tender. When the pot is quite full give it a gentle knock upon the bench to finally settle the soil, and as soon as all are finished place them in a cold frame facing north, and give a gentle watering with the rose on the pot. I always water them over the leaves, and I find by doing so they are kept clean and free from the green fly, which is their greatest enemy. Cinerarias are very fast-rooting plants, and they will soon require another shift. To know when they need it turn a plant carefully out of the pot; and if the roots have reached the sides and are running through the drainage repot again immediately, for if the roots once become closely matted the plants will be crippled in their growth. Eight-inch pots should then be prepared in the same way as before mentioned, using the same compost for the potting; after this shift the frame should be reversed, as the season will now be advanced, and the plants will require a south aspect. It will be necessary to shade them for a few days if they should flag after potting, keeping them well watered over the leaves. The principal object is to keep them growing freely. By the time they have filled these pots well with roots the plants will have attained a sufficient size for all ordinary purposes, but if large specimens are required they must have another shift.

They are best without heat if they can be protected from the frost, and where there is neither greenhouse nor heated pit they will be safe in a cold frame through ordinary winters if it is covered every night with mats or litter, and when frost is severe in the day as well. It will also be necessary during very severe weather to pack round the sides and ends of the frame or pit with dry leaves or litter of sufficient thickness to keep the temperature a little above freezing point. Another way is to dig a pit in a dry situation deep enough to sink the frame level with the ground line. By this method the cultivator will have less difficulty in preserving the plants from the effects of frost. During severe weather it will sometimes be necessary to keep the covering on the glass for a long time. I have known such structures covered and the plants kept in darkness for as much as a fortnight without injury, but on all favourable days they should be uncovered and moderate ventilation given. The plant will grow and be healthier in such a situation than in greenhouses, but will not come into flower so soon as plants grown in heated pits. Whilst in the cold frame I would recommend a bottom of roughish ashes for them to stand upon, which will not only allow all surplus water to drain freely from the pots after watering, but prevent the worms getting into them, and check the inroads of slugs and snails, which are very fond of the young foliage. At all times a sharp look-out for the green fly must be kept, and soon as the first one is discovered the plants should be fumigated.

I especially caution the amateur against employing too much artificial heat, which should not as a rule exceed  $45^{\circ}$ , and in no case more than  $50^{\circ}$ . Any attempt to unduly force the Cineraria is certain destruction. As soon as the flowerstems appear they are greatly assisted by an occasional application of weak liquid manure, which increases the strength of the plant and imparts a richer tone to the foliage, also adds to the size of the flowers. When the flowerstems are well advanced and the flowers appear the plants should be placed in the greenhouse or conservatory, giving them the lightest and most airy situation in the structure. If the flowerstems are numerous, causing the flowers to be too crowded, it is a good plan to employ a few sticks to tie the stems to, and the flowers will then be seen to a greater advantage and the plants be benefited by a freer circulation of air among the branches.—J. WALKER.—(Abridged from a Paper Read at Sheffield.)

#### FLETCHER'S PATENT METAL SUBSTITUTE FOR PUTTY.

MR. FLETCHER (Fletcher, Lowndes & Co., 13A, Great George Street, Westminster) has submitted to us this invention for affixing glass in horticultural and other structures where glass is needed. As is stated by the inventor, "the metal substitute for

putty is formed of such a section of hard incorrosive metal that shall lie evenly and with a uniform pressure upon the surface of the glass, however uneven such surface may be; and can be adapted to any form of glazing bar, whether in wood or metal, now in ordinary use." The section fig. 37 shows the appliance as used without a sashbar; indeed in this form it is a substitute for a bar as well as for putty. Fig. 38 shows its applicability to an existing bar, and thus rendering putty and paint superfluous. The form of the metal is such as to grip the glass tightly, in this respect being perfectly safe against high winds, while it is sufficiently elastic to yield to pressure, such as the expansion of water during frost, and for the removal and replacement of squares as may be needed. The inventor also claims for his plan of glazing the

Fig. 37.

Fig. 38.

advantage of being 10 per cent. less costly than ordinary glazing with putty and paint. This of course we have not tested, but we can testify that the example submitted to us was thoroughly efficient, and combined firmness, elasticity, simplicity, and durability. By this mode of glazing we have no doubt a roof would be safe, sound, and waterproof.

#### ROSES ON THEIR OWN ROOTS.

FOR many years has this subject been discussed, not in a series of papers as seasonable hints, nor with anything like that degree of earnestness which its importance renders it worthy of, but rather with a vague uncertainty and a mingling of inquiry and suggestion than an explicit statement of facts—results achieved and cultural details. Nor have we far to look in search of the cause of the general negligence of what should be a popular method of the culture of such an universal favourite as the Rose. It is owing, I think, chiefly to the fact that nurserymen do not offer Roses on their own roots. New kinds of stocks crop up—seedling Briars and so forth—but "own roots" are kept in the background, simply, I suspect, from the large quantity of stout thoroughly developed wood that must be employed in making cuttings by the thousand, which wood could not well be obtained even in our largest nurseries without such a mutilation of the stock as would materially affect its value.

Long ago the idea of growing Roses on their own roots occurred to me; and the attempt to do so proved so successful, and the bushes so superior to all others, that cultural details from making the cutting and onwards through the entire process of the development of a finished specimen were given at length in the pages of the Journal. Cuttings of stout firm wood of the current year's growth were made early in autumn, inserted in sandy soil in a cold frame, transplanted to a nursery bed as soon as the roots were sufficiently forward in spring, and by generous treatment and careful stopping and training elegant cone-shaped bushes some 4 to 5 feet high were produced in two years. A few late flowers were allowed on them in the autumn of the second year, and in the third season they were laden with bloom, and were literally pyramids of beauty, offering a striking contrast to the stiff unsightly standards that are still grown by thousands. Nor could the dwarfs from which the Rose exhibitor cuts his choicest flowers bear favourable comparison with them; for his aim is to produce excellence in foliage and blossom, and he is quite content if each plant has three or four stout shoots, each crowned by a single good flower. But then such growth most readily affords him precisely what he wants—a few fine flowers, and nothing more, an object totally at variance with that of the professional gardener, who requires fine flowers and plenty of them, so disposed as to be attractive individually and collectively. To him, therefore, Roses on their own roots, trained as I have shown, are infinitely preferable, provided he is able to bestow the requisite amount of attention upon their culture; for all Roses like generous living and soon deteriorate without it. It is true enough that they will live

and blossom in a feeble way for many years with very little attention, but they are the reverse of ornamental.

Now the growth of a Rose is naturally so pliant when young that it may readily be trained to any form that individual taste may suggest, and one may usefully inquire why this valuable property is not turned to account to impart greater variety and beauty so as to relieve the too common monotony of Rose gardens. Not that one would altogether advocate the formation of a garden full of Rose bushes trained with mathematical precision, however elegant in design; rather should we strive to impart variety under the pleasing guise of bowers covered with "Lovely Ramblers," pillars, arches, banks, whereon there should be a freedom and luxuriance of growth imparting an air of semi-wildness and with something of the grace that in the wild Rose so much attracts our admiration.

In Lady Barker's charming book "A Year's Housekeeping in South Africa," occurs a description of her garden in "Fair Natal," of which she says: "The feature of this garden was Roses—Roses on each side whichever way you turned, and I should think of at least a hundred different sorts. Not the stiff standard Rose tree of an English garden, with its few precious blossoms to be looked at from a distance, and admired with respectful gravity. No; in this garden the Roses grow as they might have grown in Eden—untrained, unpruned, in enormous bushes covered entirely by magnificent blossoms, each bloom of which would have won a prize at a Rose show. There was one Cloth of Gold Rose bush that I shall never forget; its size, its fragrance, its wealth of creamy yellowish blossoms. A few yards off stood a still bigger and more luxuriant plant some 10 feet high, covered with the large delicate and regular pinkish bloom of *Souvenir de la Malmaison*. When I talk of a bush, I only mean the especial bush which caught my eye; I suppose there were fifty Cloth of Gold and fifty *Souvenir* Rose bushes in that garden. Red Roses, white Roses, Tea Roses, blush Roses, Moss Roses, and last, not least, the dear old-fashioned homely Cabbage Rose, sweetest and most sturdy of all. You could wander for acres and acres among fruit trees and plantations of Oak, and Willows, and other trees, but you never got away from the Roses. There they were, beautiful, delicious things, at every turn; hedges of them, screens of them, and giant bushes of them on either hand." And she adds further on, "It was emphatically a poet's or a painter's garden, not a gardener's garden."

Very much like a page of the "Arabian Nights," is it not? Only we know it is a literal statement of facts often dwelt upon by other sojourners at the Cape, and we are also aware of the tantalising fact that much of the wonderful luxuriance is owing to the climate. Do we, however, do all we can to promote luxuriant growth? I have frequently seen Roses on their own roots in very rich soil throwing up numerous shoots from beneath the surface, and such shoots are justly termed suckers, for they would soon rob the old growth of its requisite nourishment from the roots if pinching or training were resorted to. Yet if such bushes were allowed to grow almost wild, only cutting away weakly growth, what a wealth of blossom would the "suckers" yield if left unshortened and bent a little, for then every bud would give us a flower-bearing shoot. The idea is not at all original, for I have repeatedly seen it acted upon with more or less success. There are soils wherein Roses will flourish for years, but in poor thin soil there is nothing for it but constant high feeding; and in view of this, the preparation of wide deep stations in the first instance would be true economy, for then simple supplementary supply of manure would suffice for a considerable time. "I could a tale unfold" of success and failure in a thin soil that would convey a useful lesson, for it has been my lot more than once to see a garden of Roses grow to full beauty and dwindle to extreme unsightliness.—EDWARD LUCKHURST.

#### SPRING FLOWERS IN IRELAND.

THE present condition of some of the popular spring flowers out of doors may not be without interest, as indicating the effects of the winter on them:—

*Wallflowers*.—At this time last year I could have gathered a bouquet of these flowers, but now the double and semi-double Germans have been almost completely destroyed. I had two lines, one on each side of a central avenue, of double yellow grown from cuttings, and the other semi-double coppery brown. But little remains of either, though protected with high walls on each side, and in a southern aspect. Have any of your correspondents noticed in their collections that in several instances one branch remained quite safe, all the others being destroyed on the same plant? The singles seem somewhat hardier; but the gusty winds caught many of them while the soil was frozen and broke them at the base. Those that remain are now showing their flowers.

*Cheiranthus præcox* appears uninjured, and although later I have determined to have plenty of it in future. The question is well worth discussing—What is the best method of treating Wallflowers during the winter with the view to early blooming? Grown in boxes and placed in a cool vinery or orchard house as a friend suggests, would not meet the case, as 20° of frost has been registered in such houses, and heat is not to be thought of for Wallflowers that it is wished to grow robust and stocky.

*Polyanthus*.—These will be several weeks later than last year too, though some blooms have been opening for the past fortnight. They are, however, inferior in size and substance, probably owing to the inactivity of the roots; in fact they must have been several weeks in a state of torpidity. I had the more tender of the gold-laced and some seedlings under safe cover, but they seem no better than those exposed. The effectual frost-resisting mantle of snow is probably the explanation, and the same applies to all procumbent winter and spring flowers out of doors. After the snow had melted, dwarf *Silenes*, *Anemones*, *Limnanthes*, *Saxifraga granulata*, hardy *Primulas*, *Phloxes*, and some early bulbs all seemed quite fresh; even some *Turban* and French *Ranunculus* that had been forgotten. And stranger still, I had a bed of *Fuchsias* last year which I cut down early in autumn to help them to retain their vitality over the winter, and, with merely coal ash protection and by mulching, buds are already starting from the bases, though many persons have lost the greater part of their stock placed under shelves in cool greenhouses. With the same treatment I expect *Salvia patens* and *Marvel of Peru* are safe.

*Alpine Auriculas*.—Owing to their wonderful adaptability these should be grown everywhere and by every lover of hardy flowers. No other outdoor plants seem to have suffered so little. The cabbage-like foliage now looks promising, and this applies to named and edged varieties grown on specially made outdoor open stands. In my limited collection I never see green fly or woolly aphids, and I believe the secret is cool treatment and comparatively small pots. I find a great tendency to unsatisfactory growth from overpotting. I am not sure, though it may be want of taste, that I do not enjoy more the fine robust foliage, softly shaded colours, and generally delicious sweet scent of the Alpines to the more tender-edged varieties with their richer colours.

*Lilies*.—Except the advancing foliage on *L. candidum*, I am not aware of any outdoor Lily having sustained injury, except I include *Belladonnas*, which were seriously affected. *L. auratum* in peat beside *Rhododendrons* were out of the reach of any cold, and the same may be said of the *tigrinum* group. In a garden near here *L. giganteum* has been outside for years, and except for division *L. lancifolium* (*speciosum*) has not been touched, though it makes an excellent conservatory plant when coolly grown outside in pots. The *Martagon* group is safe, and deserves a place in every border. *Fritillarias* I grow outside, and lost some in a frame this year. Nile Lilies (*Richardias*) were killed when near the glass, even in sitting-rooms, and must have run serious risk planted out in ponds or beds of rivers. Late Brompton Stocks, *Pentstemons*, *Ixias*, *Sparaxis*, *Schizostylis*, *Babianas* are amongst the killed here; while *Pansies*, *Carnations*, the great majority of the *Antirrhinums*, *Eschscholtzia*, double *Daisies*, and bulbs, *Violas*, *Sweet Williams*, and hardy *Veronicas*, *Pinks*, *Pæonies*, and beds of *Primula japonica*, mulched are doing admirably.—W. J. M., *Clonmel*.

#### PROTECTING FRUIT TREES.

AS your Journal stands pre-eminent for forwarding the interests of fruit-growers, I should be glad to see a discussion in your columns as to the best methods of protecting the blossom during the next few months from the frost, which probably is alone responsible for diminishing annually by more than 50 per cent. the fruit crop in this country. Why should our orchards be cultivated in this nineteenth century on the same principles as to this matter as they were a thousand years ago? Surely the advanced state of art and invention might afford some efficient and practical plan at least to protect the smaller trees. The question of cost has hitherto been the difficulty. I enclose a sample of light jute netting (4 ozs. per square yard), only a very light web being requisite. Can any of your many practical correspondents show how to apply it to the purpose desired?—W. S. MANNING.

#### BLUE ROMAN HYACINTH.

I WAS glad to find on page 106 of the Journal that this Hyacinth has some admirers. In answer to "L." I may say that I am not a grower of flowers for the market, and therefore my remarks are not made from that standpoint. If "L." admires it, and the lady he has to please appreciates it, I should say, By all

means grow it. As a decorative plant it is useless in my estimation, and for that purpose cannot be compared with *Scilla siberica*, which is both pleasing in colour and compact, while the other is loose and straggling. With me it has proved anything but well adapted for forcing, and on that account possesses but little to recommend it. As stated, I have tried it for two years, and treated it in every respect as I have the white Roman Hyacinth and early kinds of *Narcissus*. The former I had in flower the last week in October, and the latter early in November and onwards. These were all over before a flower appeared on the blue Romans, which I endeavoured to bring forward under the same conditions. It has proved no earlier with me than such varieties as Charles Dickens and others. The old bulbs of such varieties that are grown in pots or those that are planted in the flower garden will, if taken care of and placed in pots, pans, or boxes, produce earlier and better flowers than the blue Roman is capable of doing. Many of the bulbs I had for early work did not flower this nor last year, hence my remarks on page 92. I may say in reply to Messrs. Jones & Sons, that had it proved of any use to me for forcing to supply blue flowers for cutting or decoration, I should have been the last to condemn it. Perhaps Messrs. Jones & Sons will give me further details when their bulbs were potted, when introduced into heat to have them in flower at Christmas, and the length and quantity of foliage when the flowers appeared? In foliage mine was very productive and straggling. I shall be very glad to pay Messrs. Jones & Sons a visit about next Christmas if they will kindly announce in the "Notes and Gleanings" in the Journal about that time when they have blue Romans in good condition.—CULTIVATOR OF BULBS.

#### GARDENING SCRAPS.

I HOPE you will think the following scraps worth a place in the Journal, as they may be useful, suggestive, or elicit serviceable replies:—

**BRUSSELS SPROUTS.**—A short time ago you did me the favour of publishing a few inquiries which I sent you about the best mode of treating and producing the finest Brussels Sprouts. Your pages show a very interesting expression of opinions on the subject, and I now wish to state a few observations of my own. Last summer or autumn some sheep got into a neighbour's garden and nibbled out the heads of the Brussels Sprouts. Those plants produced the earliest and finest sprouts I have seen, but then they were soon done and the plants died. Now those I have with the heads on have produced and are producing a good crop of sprouts, and will, I think, produce, as the same kind of plants have done in previous years, a most abundant supply of bloom shoots, which if cut and cooked just before the bloom expands is one of the most delicious and delicate vegetables that can be placed on the table. They should be tied in bundles, boiled, and sent to table as Asparagus is.

**FLOWER GATHERERS.**—Last summer I had given to me a pair of scissors, or more properly "flower gatherers," which when they cut the flower or spray of bloom off the plant hold it conveniently for the collector. Having to cut some Roses from plants against a wall higher than I could reach, I improvised a means of gathering them by splicing the scissors to the head of a fishing-rod, and working the cutting side by the line through the rings. May I ask if any of your readers can recommend any more scientific apparatus for gathering flowers off lofty plants? The scissors were stamped "Webster," but no address.

**MUSHROOMS IN PASTURES.**—I wish to impregnate a garden and field this year with Mushroom spawn. When is the right time for putting the spawn into the open ground, and at what depth?

**JERUSALEM ARTICHOKEs.**—If you wish to enjoy the true flavour of Jerusalem Artichokes, never have them dug out of the ground in which they are planted until the day you wish to eat them.—G. O. S.

#### FREESIA REFRACTA VAR. ALBA.

SUCH a charming plant as this unquestionably is can scarcely be too highly recommended, and when its merits are more generally known it will speedily become one of the most popular plants for the greenhouse and similar cool structures. Graceful habit, pretty flowers, delicious fragrance, easy culture, and quick increase constitute an association of good qualities amply sufficient to render any plant worthy of attention; but this *Freesia* possesses, in addition to those named, the valuable characters of producing its flowers early in the year, and of remaining attractive for many weeks. What more could be said in its praise?

From the beginning of the year several specimens have been

flowering in the house devoted to Cape plants and Heaths at Kew, and have been greatly admired by all who have seen them. One or two bulbs in a 60-size pot, with their narrow Iris-like leaves and spikes of white flowers, are seen to excellent advantage when the pots are arranged as they are there in the front of taller plants on a stage near the glass, and in a greenhouse among plants with brighter-coloured flowers a few potfuls would be most welcome. Larger size pots may also be employed, but I think the others are more suitable, and the plants thrive in them remarkably. A light turfy soil with a moderate proportion of sand and good drainage, will meet all the requirements of the plant, except that a season of rest is needed after the growth is completed to ripen the bulbs, which may be effected by lessening the supply of water and placing the pots in a position well exposed to the sun. At other times water may be given freely if the drainage be effectual. Increase is readily effected by separating the offsets from the old

Fig. 39.—*Freesia refracta* var. *alba*.

bulbs when repotting them in early autumn, and in this manner a stock can soon be obtained.

The annexed woodcut fairly shows the form of the flowers, but it is difficult to do full justice to the plant by representing only a portion of its growth. The leaves are narrow and tapering, 6 to 9 inches long, arranged in a flattened manner like a diminutive Iris; the spikes are a little longer than the leaves, bearing near their summit three or four funnel-shaped flowers, with six roundish lobes; the tubular portion is about 2 inches in length, yellowish at the base, the limb being 1 to 1½ inch across and pure white. The fragrance is powerful yet delicate, compared by some to the odour of Primroses, which it certainly resembles, but with a little of the peculiar richness characterising the flowers of *Dendrochilum glumaceum*. The flowers last well when cut, retaining their fragrance until they fade, and a few will perfume a large apartment.

This variety, which is very distinct from the species, was first exhibited by the New Plant and Bulb Company at a meeting of the Royal Horticultural Society, July 2nd, 1878, when a first-

class certificate was awarded for it, and a similar award was also granted for it at one of the Royal Botanic Society's Exhibitions. Mr. Ware of Tottenham has a stock of the plant under the name I have employed, which is the one accepted at Kew.—L. CASTLE.

#### PRIZES FOR LABELS.

WILL you allow me to ask any of your readers who are using at all out-of-the-way plant labels, and all label makers, to send specimens as soon as possible to the Society of Arts, John Street, Adelphi? I hope the Society will get up a good exhibition, and then hand over the exhibits to the Royal Horticultural Society. The prize would have been offered through the latter Society had I not thought that in the Society of Arts many ingenious heads would be led to consider the subject for the first time, while in the Royal Horticultural Society most—or at any rate many—of the Fellows know by sad experience the want of a thoroughly satisfactory label; besides, as an old member of the Society of Arts Council, I knew the Society's influence and power of publication.—GEORGE F. WILSON.

#### NOTES ON BOILERS AND THEIR HEATING POWERS.

WHILE the severe winter is still fresh in our memory I write these few remarks, and while giving my own experience I desire that your readers will record theirs. More especially do I wish for the co-operation of your scientific correspondents in a few plain inquiries.

First, can anyone give me the difference in heating power of a Witley Court boiler with two flues, said to heat 1200 feet of 4-inch pipes, and a Wright's Endless Flame boiler to heat the same length of piping? By difference I mean, Which is the best for hard work and which is the most economical? I have had no practice with either of the above, but wish to ascertain all I can from practical men as to their utility. In setting, which would take the least depth? Is it advisable for the flow from any boiler to dip from the top of the boiler to enter the main, especially if I have several houses attached?

I found in practice this winter that a 4-feet saddle boiler with check bridge, which is estimated to heat 1000 feet of 4-inch pipes and in ordinary weather 1300 feet, will in severe time heat a lean-to Cucumber house 80 feet long with five rows of pipes on the surface and three under the bed, thus making 700 feet; and the same boiler heats one division of early vinery 60 feet long, six rows of pipes, say 400 feet of piping—1000 feet in all; the vinery at 55°, and the Cucumber house at 65°. To maintain this temperature with the chimney damper out 3 inches and the bottom doors open, requires attention at night every four hours in sharp frost. Apart from the question of extra labour and attention in firing, should I save by having larger boilers? and if so how much larger? My own idea is that a large boiler in temperate weather is not as economical as a smaller one. On the other hand, I believe that a fire which often needs replenishing wastes fuel. Supposing I had larger boilers, would this necessitate greater consumption of fuel?

In another case here I have a boiler of the same size and make to heat a Cucumber house 70 feet long with six rows of pipes on the surface and two under the bed, but this house is 40 feet from boiler, and can this be considered as good for heating as a house close to boiler? I have 600 feet length in this house. Now I am heating a span vinery 50 feet long with four rows of pipes, and another with one row only all round, this bringing it up with the mains to about 1000 feet. I cannot maintain the heat I require in this Cucumber house when the others are at work unless I keep up a very good fire; I therefore propose adding another boiler and connecting the whole of the boilers, so that I might work the three together in severe times or separately as required. I have a 50-feet span Muscat house and 60-feet early vinery unemployed, being afraid to trust to my present boiler power. I have houses at 40°, 60°, and 70°; but if it takes a good fire to get the heat when there is no frost, how must it be when there is say 20° of frost? To be safe I should suppose if a boiler is estimated to heat 1000 feet it would only work 500 feet in severe weather. This is the conclusion I arrive at. On the other hand, I again maintain a larger boiler than what is really required is not the most economical, and to overcome the difficulty a supplementary boiler would have to be added. To go a step further, I may say I consumed for about eighteen months, or rather from October, 1879, to this time, 80 tons of fuel in equal proportion of coal and coke. Perhaps some will say how this quantity agrees with theirs. On the coal and coke question I would say a few words. I like coal for very sharp weather, as it raises heat quicker than coke; but I find when the heat is up coke is the most powerful and lasting.

A ton of coke costs me the same as coals; which should give most heat? My mains are all smaller than inside pipes, thus 3-inch mains running into 4-inch pipes. Do your readers agree with this?

Briefly I sum up my case thus: I find the nearer the houses to be heated are to the boilers the quicker are they heated and the better is the heat maintained. A good boiler which heats a given number of feet of piping now, would in severe times require the assistance of another boiler; or, to put it in another way, Which is the cheapest to keep up—a 3-feet boiler to work a given number of feet of piping, or one, say, 5 or 6 feet? In one house I have a 2-inch main to it, and this always heats quickly, and there is little difference in the heat of the return and flow pipes; this I attribute to its quick circulation. I know it is not possible in all cases to do without long distances from boiler to house, but I maintain that the nearer the house to be heated is to the boiler the better it works, even though mains be eased and kept from the weather. I also find that one flow pipe running into two returns gives as much heat as two flows and two returns, the heat through the one flow seems to be so powerful.

How many of your numerous readers have been able this winter to make up the fires at 9 P.M., and leave them until 6 or 7 next morning? I have been told of one such instance this season, but in this case they must be well supplied with boiler power. Speaking from my own practical experience, and from what I have seen since 1859, I never yet was so fortunate to meet with such a case, nor did I ever see or hear of such until now. In ordinary weather, of course, I could do this, but not in the past severe winter. I might also ask if there be any who see no use for dampers in chimneys, as I am told they are not required, the draughts of the fire to be regulated by ashpit doors. I do not attempt to say which is the best form of boiler, nor do I wish to disparage any form. Doubtless there is no boiler but what the maker or inventor could work well and make it succeed, and another one would fail at the same boiler. I consider that not nearly so much care and attention is given to stoking as ought to be done; in many cases it is simply opening damper and doors and throwing on the fuel as necessary.—STEPHEN CASTLE, *The Vineyard, West Lynn, King's Lynn, Norfolk.*

WE have again to approvingly notice Miss E. A. Ormerod's annual production, "NOTES OF OBSERVATIONS ON INJURIOUS INSECTS," the report for 1880 having just been received. As usual it contains a large amount of useful information regarding the insects which infest the chief garden and farm crops. Descriptions of the habits of the various species are given, with particulars of the methods which have proved efficacious in destroying them, and as the latter are the experiences of practical men they are thoroughly reliable. The authoress cordially acknowledges the great assistance she has received from her numerous correspondents, and announces that the next report is likely to be on a much more extended scale, as contributors have so largely increased in numbers. It is also stated that a work is in preparation by the same lady upon the remedies and means of prevention for the attack of insects on food crops, forest trees, and fruit, which will undoubtedly prove of considerable interest and utility both to gardeners and farmers. We may remind our readers that the report we have briefly noted is published by Messrs. W. S. Sonnenschein & Allen, 15, Paternoster Square, London, and by Messrs. J. Menzies & Co., Hanover Street, Edinburgh, price 1s. All inquiries or information upon this subject should be addressed to Miss E. A. Ormerod, F.M.S., Dunster Lodge, near Isleworth; the Rev. T. A. Preston, Marlborough; or E. A. Fitch, Esq., Maldon, Essex.

— "D. L. M." states that he has had a charming display of Snowdrops in pots obtained by digging up some clumps of the single variety from the borders immediately the frost departed

and potting them. They have, he says, surpassed bulbs that were purchased and potted in November, and he recommends the above "simple mode of having charming masses of Snowdrops under glass."

— WE have received from Messrs. Ellwanger & Barry of the Mount Hope Nurseries, Rochester, New York, "A DESCRIPTIVE CATALOGUE OF SELECT ROSES," which possesses several distinct and commendable features. In addition to full and lucid descriptions of most of the best varieties, particulars are given of the parentage, names of the raisers, and the years when the varieties were sent out. For instance, under *La France* we have "(Guillot fils, 1867), raised from seed of a Tea Rose;" and under *Madame Lacharme*, ("Lacharme, 1873), a seedling from Jules Margottin." The catalogue is accompanied by a coloured plate giving good representations of *Coquette des Blanchés*, *Jean Liabaud*, *Climbing Jules Margottin*, *Alfred Colomb*, and *Marie Van Houtte*.

— IT is announced that the ROYAL SOUTHAMPTON HORTICULTURAL SOCIETY will hold their Summer Show on Saturday and Monday, July the 30th, and August the 1st; the Chrysanthemum Show being fixed for November the 22nd and 23rd. As usual liberal prizes are offered in numerous classes, and with favourable weather no doubt the Exhibition will prove very satisfactory. All inquiries should be addressed to Mr. C. S. Fuidge, Secretary, 39, York Street, Lower Avenue, Southampton.

— A SPECIMEN of the beautiful RHODODENDRON COUNTESS OF HADDINGTON has for more than a month past been flowering in the greenhouse at Kew. It is one of the oldest of the hybrids, so admirably suited for cultivation in such structures, and is also one of the best, although it now has many formidable rivals. The plant, like many of its relatives, is not quite so compact in habit as might be desirable, but it forms a moderately close head when well grown, and produces its flowers very freely. These are borne three to six in a loose umbel, and have a bell-shaped corolla, which when fully expanded is 4 to 5 inches across. The inner surface is white, the outer tinged with a delicate rose hue; and the flowers further possess the additional attraction of an agreeable odour. The leaves are elliptical in form, about 4 inches long by 2 in width, slightly ciliated, and bright green. The plant is, we are informed, the result of a cross between *Rhododendron Gibsoni* and *R. Edgeworthii*, and is thus similar in its parentage to *R. Duchess of Buccleuch*. It was raised by Mr. Lees, formerly gardener to the Earl of Haddington at Tynninghame, East Lothian.

— THE Committee of the LIVERPOOL HORTICULTURAL ASSOCIATION have elected their officers for the ensuing year—A. B. Forwood, Esq., as President of the Association; W. B. Halhead, Esq., and Mr. Richardson were re-elected respectively as Treasurer and Chairman. It was decided to hold their annual Summer Show, as last year, on Saturday and Monday (Bank Holiday), July 31st and August 1st, as advertised in another column. It was also decided to hold a Chrysanthemum Show in November, of which due notice will be given.

— CONCERNING the WEATHER IN THE EARLY PART OF THE WEEK, Mr. B. Cowan writes from Durham—"Snow and sleet fell at intervals from Saturday and all day Sunday. To-day (Monday) snow has fallen incessantly all day, the average depth being about 5 inches, with strong N.E. winds." Mr. W. Iggulden writes from Somersetshire—"There was a rather heavy fall of snow on Sunday, much of it still remains. The thermometer stood at 18° on the night of the 27th, and on the 28th at 16°." In London also on Tuesday a minimum temperature of 23° was registered.

— AMONG useful cool-house Orchids ONCIDIUM CUCULLATUM is well known, and though certainly not one of the most showy

it is by no means to be despised. Several varieties are met with in collections, but one of the finest we have seen is now flowering in Messrs. E. G. Henderson's nursery, Maida Vale, where its superiority over the ordinary forms is clearly shown, as several are flowering in the same house. The sepals and petals are similar to the type, perhaps slightly darker in colour; but the lip is of unusual size, exceeding an inch in diameter, the spots being large and of an extremely rich purple tint.

— WE are requested to note that the HORSHAM ROSE ASSOCIATION will hold their fourth annual Exhibition on Thursday the 5th of July.

— WHILE passing through the house devoted to succulent plants at Kew one day last week our attention was drawn to *ALOE LYNCHII*, which was then flowering for the first time. It is a hybrid raised several years ago by Mr. R. I. Lynch, after whom it has been named by Mr. J. G. Baker, who has given much attention to these plants, and has recently made some alterations in the nomenclature of *Aloe* and allied genera. The hybrid named above is not only interesting from its appearing to combine the characters of the parents, *Aloe striata* and *Gasteria verrucosa*, in a very marked manner, but it is also very neat, and might even be considered pretty. The leaves are smooth, slightly curved upwards, 10 inches long, 2 inches broad at the base and tapering to the apex. They are in size and form very much like the *Aloe* parent, but they have a number of white spots upon a light green surface, in that respect being suggestive of *Gasteria verrucosa*, though not raised as in that species. In general habit the plant resembles the last named. The inflorescence is a panicle more than 2 feet in height, with spreading branches, bearing tubular flowers about an inch in length, light orange colour at the base, and the upper portion greenish white. The plant is very interesting botanically, and by no means devoid of attractions in a horticultural point of view. Mr. Lynch informs us that the seed-bearing parent was *Aloe striata* (*A. albocincta*) although several were crossed reciprocally.

— WE are informed that the GLASGOW AND WEST OF SCOTLAND HORTICULTURAL SOCIETY have fixed their Shows for 1881 to be all held in the Glasgow City Hall, on Wednesday the 30th of March, and the 7th and 8th of September.

— A CORRESPONDENT sends us the following note upon EXTENSIVE CUCUMBER CULTURE—"Mr. James Whittaker of the Prescot Nurseries, has just finished planting his new Cucumber house, which is 197 yards long, and contains eight wells of water. Some idea may be formed of Mr. Whittaker's Cucumber-growing when we state that in the season he sends from his nurseries over three tons weekly. In his new house he purposes constructing a tramway for running small waggons on."

— THE schedule of prizes to be competed for at the forthcoming Summer Show of the WIMBLEDON AND DISTRICT ROYAL HORTICULTURAL SOCIETY has been finally settled, and will in due course be distributed. There are some important alterations made in it may be briefly mentioned. Three prizes are offered for a group of miscellaneous plants to cover a space not exceeding 100 square feet, open to all comers. There is also liberal provision for groups in the gardeners' and amateurs' division. The introduction of groups into the Show will no doubt render it more attractive. In the amateurs' division classes have been added for flowering Begonias and Coleuses, while the value of the prizes has been increased in the classes under each heading where practicable. Sir Trevor Lawrence, Bart., has consented to act as President, and has also offered a special prize for competition. The following gentlemen have likewise signified their intention of giving special prizes—viz., the Rev. J. M. Brackenbury; F. W. Parsons, Esq.; A. Schlusser, Esq.; J. F. Schwann, Esq.; R. S.

Dean, Esq.; J. J. Casswell, Esq. The Society also continues its prize for button-holes, and several other special prizes are expected. The Show will be held at Woodhays, Wimbledon; L. Walters, Esq., having generously placed his grounds at the disposal of the Committee. Any information on the affairs of the Society will be readily given by the Secretary, Mr. H. A. Rolt, Maud Villas, Gladstone Road, Wimbledon.

#### CHAPTERS ON INSECTS FOR GARDENERS.—No. 19. NEW SERIES.

THE moral force of a proverb sometimes quoted in favour of the habit of early rising, that "the early bird catches the worm," has been weakened by the insinuation that the worm must be up as early, or perhaps earlier than the bird, otherwise it would not thus fall a victim. By a wise natural provision there is a harmony, so to speak, between the movements of birds and those of the living creatures upon which many feed. Vegetable food falling short in

Fig. 40.—*Scolytus destructor* magnified.

Fig. 41.—*Tomiscus typographus* magnified.

the opening months of the year, birds of various species hunt eagerly after such insects as may be stirring, nor do they hesitate to seize and devour some of those hard-cased beetles which may seem to present uninviting morsels. Not a few insects also, beetles and others, are brought into view by the changes produced upon the soil by the frost or the rains, and their hibernation comes to a sudden finish. Many soft larvæ and pupæ are devoured in early spring by birds, by other insects, and even by slugs.

Proceeding with our notice of the weevils we reach a destructive family, the Otiorhynchidæ, so called from the ear-like appendages on each side of the short thick beak. Almost all the species here are injurious, and a large proportion of them are general feeders. About the bulkiest of them, and perhaps on the whole the worst as a foe to succulent plants, is *Otiorhynchus sulcatus*, a handsome species, its black and grooved wing-cases having a velvety down upon them. This appears during the summer when the female beetles, by night usually, deposit their eggs in the stems of plants

Fig. 42.—*Tomiscus typographus* flying.

just below the surface of the earth. The larvæ hatch out soon after—fat whitish grubs, minus legs, but armed with stiff hairs, by means of which they wriggle for short distances. Their proceedings go on through the winter, the larvæ thriving at the expense of the plants in which they are burrowing until May, when they are fully grown. *O. picipes* is also a pretty species. The larva is a subterranean feeder, but the mature beetle does greater damage than the larva generally, coming out in companies during April and May to bite the young leaves. This is less than the preceding, chestnut brown, and curiously marked with circular lines. To specify another of this family we take *O. tenebrius*, an insect that from its partiality to the Apricot has been termed the "Apricot beetle," a dusky black species, with the head, thorax, and wing-cases thickly dotted and punctured. Here again mischief is done both by larva and beetle, although it weakens rather than destroys the fruit trees it visits. Besides the Apricot all trees against walls are particularly liable to be affected; Vines are attacked in hothouses, where the larvæ are occasionally detected at the roots. Gardeners have already been

strongly advised to see all crannies in walls thoroughly closed, so as to afford no hiding places to the beetles. Special attention ought to be given besides to the base of walls that enter earth. Not only these beetles, but a variety of noxious insects, seek such positions during the colder months. It is odd that the last species should seem to have a preference for chalky districts.

The family of the Eirrhinidæ have received their Greek name from their lengthy beaks; amongst these is great variety in form, size, and habit. *Pissodes Pini* is a little Scotch species, having an egg-shaped body spotted with brown and gold; this resorts to Pine forests, the larva living in the trunks of trees, where it forms galleries between the bark and the solid wood. More generally diffused are the species of the genus *Anthonomus*, the larvæ belonging to which feed on flowers, as in the instance of the Apple weevil (*A. pomorum*). Less than a ladybird, this tiny beetle checks the development of much promising Apple bloom, the females being armed with long ovipositors, by which they deposit eggs within holes they bore into the calyx at the season of flowering. One egg is placed upon each flower visited. The result may be well described in the words of that skilled entomologist the late Edward Newman, who says, "The bud continues to grow like other buds, the perforation becomes invisible; by-and-by the egg bursts and out comes a little white maggot, which begins to devour the young and tender stamens; next to these the style is attacked and eaten down to the fruit, the upper part of which is quickly consumed; the maggot is then full-fed, it becomes a chrysalis, and lies perfectly still. For a few days yet the blossoms preserve their lovely pink colour, and then by degrees fade to dingy brown." When the beetles emerge later on they creep, on the approach of winter, under any heaps of refuse that may chance to be near the Apple trees.

In the genus *Balaninus*, nearly allied to *Anthonomus*, the beetles do not begin their operations quite as soon. Attacking usually the nuts of various trees, the females wait until the fruit has fairly set and the blossom fallen, when they pierce a hole with the long and curved beak. *B. nucum* is a great frequenter of the Filbert; this species is marked with brown and white, but these colours are derived from a down which easily rubs off, leaving the wing-cases black. The white grub of the nut weevil remains in the nut until it is full grown, when it nibbles an opening and descends to the ground, remaining a pupa through the winter. Hence it has been recommended to kill the adult larvæ and pupæ, by drenching the earth under the nut trees with an ammoniacal solution. The downy weevil (*B. villosus*) is even more downy than the preceding; this is happily not common with us, for its habit is to pierce the fruit of the Cherry in order to reach the stone.

The weevils that are placed in the family of the Cryptorhynchidæ have a beak bent downwards, and which is at times hidden by the insect in a groove upon the under side of the body. This is generally globular, and when one of these beetles "tucks in" its limbs, as they will, it has a close resemblance to a tiny seed. *Cryptorhynchus Lapothi* burrows in the bark of Willows, occurring frequently in large numbers, but it is considered that the injury they do is but small. Others in the family feed upon the leaves of Vetches, like the pretty *Orobites cyaneus*, with dark blue polished wing-cases. Notably injurious to grain are the species of *Sitophilus*, which includes the rice and corn weevils, and which have in some cases been sifted out of grain by the hundredweight. The damage is effected by the larvæ, which live within the grain, devouring the farina. The two species are nearly alike, but the rice weevil (*S. oryzae*) has four red spots on the wing-cases, which are absent in *S. granarius*.

The last family of the weevils have been separated by a few entomologists on account of their peculiar habits, though they have the usual beak (rather short), and also the elbowed antennæ. As they are all feeders upon wood they have received the name of Hylesinidæ. The best known of the family, and possibly the worst enemy of timber that is found amongst the English beetles, is that named *Scolytus destructor* (fig. 40), or occasionally the "Elm-destroying Scolytus," from its frequent appearance upon that tree. But it by no means confines its attacks to the Elm. This beetle is about a third of an inch in length; the thorax is large and punctured, black, as is the head, the wing-cases black or brown. The larva has very powerful jaws for its size, and a wrinkled body, which enables it to push along the grooves that it cuts along the wood. The channel made by the parent beetle is carried in for some distance, and after the eggs are laid the mother dies on the spot. Larvæ, pupæ, and perfect beetles may be found together towards the end of summer; the pupæ buried quite half an inch in the wood, the tunnel being blocked with fine particles. Doubtless *S. destructor* and similar beetles often complete the work of destruction commenced by caterpillars, such as that of the goat moth, and it is also more than probable that trees perfectly healthy are not touched by them. Allied to *Scolytus* is the genus *Tomiscus*, one species in which has

been called "the printer" (*T. typographus*) figs. 41 and 42, from the appearance of its tracks. In England, however, little harm is done by this insect; abroad, it specially injures Firs.—J. R. S. C.

#### REVIEW OF BOOK.

*Roses in Pots.* By WILLIAM PAUL, F.R.H.S. Fifth Edition. Kent & Co., Paternoster Row.

WHEN a work reaches a fifth edition no better proof is needed of its worth, nor of the popularity of the subject on which it treats.

It is stated in the preface that "the first edition of this little book was compiled from a diary of the author's observations and experience while practically engaged in the cultivation of Roses in pots, and was merely intended to meet the wants of a new phase of Rose culture. As successive editions have been called for, he has endeavoured to convert the original brief notes into more solid matter, and to convey such information as he may have gathered over a more lengthened period of practice. Roses in pots, few or many, are now seldom absent from any good garden; and while their culture is considered by some to be critical and

Fig. 43.—SPECIMEN ROSE.

difficult, the author believes that no plants are more easy to deal with, if their nature and requirements are studied, mastered, and reasonably attended to." What the "requirements" are for growing such a specimen as is shown on fig. 43, which appears in the volume, we are told in a clear plain manner that no intelligent cultivator can misunderstand. On the advantages of growing Roses in pots the author observes, "One great advantage of growing Roses in pots is, that they may be removed from place to place at pleasure when in bloom. Another advantage is, that by

this system plants may be had in flower throughout the year. Three sets of plants are requisite to accomplish this. The first, which are grown out of doors or in a cold pit, will flower from May till November; the second, which are retarded, will flower from November till February; and the third set, which are forced, from February till June." We also cite the following sound advice on the choice of plants:—"It is pretty generally known that some varieties of Roses thrive best on their own roots, and some as worked plants. Any, experienced Rose-grower will be

able to furnish the purchaser with information on this point should he need it. The ordinary-sized plants priced in the Rose catalogues are not always the most desirable. Rose-growers have usually on hand what are termed 'extra-sized' plants, and these, though somewhat more costly per plant, are really the cheapest in the end, especially for the inexperienced grower, or for those who wish to realise a good display at once. Supposing a given sum to be fixed on, it would likely prove more satisfactory to purchase a smaller number of the larger plants than a greater number of the small ones." Every phase of culture suitable for every class of Rose is detailed in the volume, and numerous illustrations are given that cannot fail to be of practical use to the cultivator. Choice descriptive lists of varieties are submitted as suitable for various purposes, indeed anything the author knows about growing Roses in pots (and that is a great deal) appears to have been told without reserve, and those who carry out the instructions given may hope to succeed as well as he has done. The engraving is no exaggerated picture of a specimen Rose, but is only a fair representation of what may be effected either in pots or in the open air, and with such examples of culture there is no wonder that Roses are popular and their culture still increasing. Incorporated with the work is the "autobiography of a pot Rose" in five chapters, which is alike entertaining and instructive. To all who are essaying the culture of Roses in pots we commend this volume of ninety-two pages, as we are convinced that it will be of much service to them, and prove a satisfactory investment.

### THE GREAT FROST AND ROSES.

FOLLOWING out Mr. George Baker's suggestion in his interesting articles on the subject, I am pruning this year a fortnight earlier than usual. I apprehend fully that extra time will be needed by Roses cut down within an inch of their lives, or at any rate within an inch of the ground, to make all the new wood required by exhibition time; I am, therefore, in a position to record the results of an investigation made upon Roses which have endured, with but a little fern protection, over 32° of frost. I am speaking now of bush Roses on own roots and Manetti. To mention those of which the pith is discoloured, as far as the pruning knife can get at them, would be to go through half a catalogue. I shall confine myself therefore to those where I have been able to find sound wood at last more or less near to the ground. Not many appear to have been killed absolutely outright except Teas, some Hybrid Teas, and Countess of Oxford. Though this variety appears specially tender it is interesting to observe an equally smooth wood of the same variety, Mdllc. Hippolyte Jamain bearing the ordeal far better. The others of which I am able to speak favourably are Abel Carrière, Alfred Colomb, Marie Baumann, Boule de Neige, Dr. Hogg, La France, W. W. Saunders, Ferdinand de Lesseps, Marie Rady, Charles Darwin, Madame Gabriel Luizet, and, I am glad to observe Madame Bellenden Kerr—this latter being a more robust variety of that most lovely but too tender Mdlle. Bonnaire. The turn of standards is yet to come.—A. C.

### KITCHEN GARDEN.

THE prolonged continuance of frost and snow has necessarily delayed many operations, which will considerably increase the number of those usually requiring attention under favourable conditions at this somewhat busy season, hence the necessity of executing preparatory work which can be done, such as having a good supply of Pea sticks, stakes, &c. To have a supply of new Potatoes from the open-ground at the earliest possible period is the object in most places, and for this a breadth of early varieties, such as Veitch's Ashleaf, Early Bird, Myatt's Prolific, or similar sorts should be planted when the soil is in a fit state, choosing a warm south border or other sheltered situation. A row planted at the base of a south wall where protection is afforded the trees will accelerate the lifting ten days or a fortnight. Potato sets should be laid out singly in a place where frost is merely excluded, and not only cool but moist, in which the tubers will keep firm, making but little growth and that of a sturdy nature.

### FRUIT HOUSES.

*Pines.*—Start a batch of suckers which are intended to furnish plants for a supply of fruit at the end of the year onward through the spring and early summer months. Prepare the materials required for potting, and the fermenting bed in some close structure to maintain a temperature of 80° to 90°, and where great fire heat will not be necessary to secure a temperature of 55° to 65° with regularity. The best developed plants selected at the beginning of last December and forwarded by an advanced temperature have fruit showing; and as it is desirable to advance the ripening of these as much as possible the temperature should be maintained at 65° to 70° at night, and 5° to 10° more under favourable conditions by day, ventilating as before advised, economising fire heat by making the most of sun heat. As the fruit advances the plants will require more water at the roots, examining other stock once a week. Recently started plants intended to form a succession to those above named must not be brought on too rapidly; 65° at night and 70° by day will be sufficient.

*Vines.*—The weather has been most unfavourable for early forcing; cold easterly winds, no sun, and snow very frequent. Keep up a good supply of moisture in the early houses, having the evaporation troughs filled with guano water, and sprinkle available surfaces in the house in the early part of the afternoon. Vines in flower set best when the atmosphere does not contain too much moisture, ventilating whenever external conditions permit, and closing early with sun heat. Shy-setting varieties when in flower should have the rods shaken two or three times a day to aid fertilisation by distributing the pollen, or dust over the bunches with a camel's-hair brush or plume of Pampas Grass. Fruiting Vines in pots must not receive a check through dryness of the soil or want of nourishment. Liquid manure may be liberally supplied, providing it be tepid and not too strong. Those Vines that have the roots extending from the pots into fermenting material should have moisture given them there as well as in the pots. Vine eyes inserted as previously advised will now be rooted, and should as soon as the roots reach the sides of the pots be shifted into 6-inch pots, placing them on shelves over the hot-water pipes in preference to plunging in bottom heat. Syringe freely amongst them, and pinch out the lateral growth as produced, unless required for planting out this season, when all growth should be retained. Muscats, Lady Downe's, Gros Colman, and other late varieties may now be encouraged, as they require a long growing season to ripen the Grapes thoroughly, for unless ripened by September they will not keep well. Little advantage will be gained by covering the outside borders with fermenting materials after this period, but means of throwing off heavy rains or snow will be beneficial. The internal borders should be thoroughly soaked with water or liquid manure at 90°. Complete the preparation of late vineries, washing the glass and woodwork, dressing the Vines, and removing the loose surface soil from the border and supplying fresh, for as a general rule all houses should be started not later than the beginning of April.

### PLANT HOUSES.

*Greenhouses.*—Camellias that flowered in the autumn are now growing, and should have a temperature of 55° at night and an advance of 10° to 15° by day, plenty of atmospheric moisture, and slight shade. Plants in flower should be shaded to ensure their greater duration. Straggling shoots should be cut back to keep the plants in shape, the best time being immediately after flowering. Any potting required should be attended to at the same time. Avoid overpotting, and provide efficient drainage. Hardwooded plants requiring more root space should be attended to at once, as the plants have then a long season of growth. Young plants will first require attention, commencing with those active at the roots. See that the soil is thoroughly moist before potting, and press it very firmly. Keep the plants rather close, not ventilating at the side of the house for a few weeks, and keep the shelves and other available surfaces well moistened, especially in bright weather. Good fibrous peat with about a sixth of crystal sand for the strong-growing kinds, or silver sand for the more delicate-rooted varieties, is a suitable compost. Do not disturb the roots more than is necessary to remove the crocks from the base of the ball, and any plants that are very much root-bound

must only be given a small shift, but healthy plants will need pots that will admit of an inch to 2 inches of fresh soil around the balls. Young plants should have the flowers removed. Azaleas, such as A. Borsig, Narcissiflora, Reine de Portugal, and others that have been forced early, should, when the flowering is over, be placed at once in a warm moist atmosphere, so as to continue the growth that was excited by placing them in heat, and enable them to continue the disposition to bloom early, acquired through early forcing. The general stock, from being more active at the roots, will require an increased supply of water, and by no means allow the atmosphere to become too dry. Acacias and other description of New Holland plants will show greater need of water, and should have more copious supplies, as when flowering or advancing thereto the roots are more or less active. Lapagerias requiring more root space should be shifted into larger pots, the plants doing well either in turfy loam or fibrous peat, it being essential that it be lumpy; and good drainage must be afforded, as very copious supplies of water are necessary.

Roof climbers, such as Passifloras, should now be spurred well in to within an eye or two of the main rods, cutting back extensions to well-ripened wood. Tacsonias should only have the growths well thinned out, removing the old and weak, encouraging the vigorous and young in their places. Assist Habrothamnuses advancing for flowering with weak tepid liquid manure, affording similar assistance to Roses planted out, mulching with short manure. Clematises employed as climbers or pillar plants should only have the growths thinned out, and, whether grown in pots or planted out, should be assisted with liquid manure. Admit air freely upon all favourable occasions, commencing at 50°, fully above that temperature, and close at the same. Hardwooded plants should have ventilation freely above 40°.

## NOTES ON VILLA AND SUBURBAN GARDENING.

### KITCHEN GARDEN.

*Cauliflowers.*—The late severe frosts have in many districts completely destroyed exposed vegetables, and they are likely to be scarce for some time to come. Some preparation should therefore be made to forward a few in frames and pits, and also to raise plants to replace those that are lost. Broccoli especially is much injured; and as many growers have lost their stock of autumn-sown Cauliflower plants, unless some of the early varieties of the latter are sown at once the break in the supply will be a lengthened one. Suitable varieties are either Carters' Extra Early, Veitch's Dwarf Forcing, and Dean's Snowball, and failing these Dwarf Erfurt and Early London. Sow the seed thinly either in a pan or box, using fine light soil, which should be kept moist, though not saturated, and place in a gentle heat. When the seeds have germinated elevate to near the glass, and give air as much as circumstances will permit. The seedlings when in rough leaf may either be pricked-out in boxes, or be potted singly into 4-inch pots, and as the stems are certain to be somewhat drawn they should be buried up to the seed leaves. Keep the plants growing steadily, hardening-off before they are crowded, the aim being to secure sturdy plants to put out on a warm border, or at the foot of a south or west wall early in April. If either of the new early varieties recommended are grown, the produce will be fit for use nearly as early as that of autumn-sown plants usually is. To maintain the supply more seed should be sown on a slight hotbed with or without glass protection, in the latter case substituting mats, and the young seedlings may either be transferred direct to the ground or be pricked-out in a warm position. Those who possess a batch of autumn-sown plants will do well to pot some of the strongest into either 4-inch or 5-inch pots, placing them in little heat till established, hardening-off and planting out on a warm border before they are become rootbound. The remainder of the batch will thus receive more space, and later on may be planted out in a good open position, protecting when necessary in each instance with either branches of evergreens or inverted flower pots. Well-hardened Cauliflower plants are proof against a rather severe frost, but if planted early and without much hardening are very liable to be much injured.

*Lettuces.*—Those who fortunately have a stock of autumn-sown

plants may soon thin them out freely, planting the thinnings on warm borders, and these will succeed those undisturbed in the frames or otherwise. The very latest sown plants appear to have been most hardy; and as these are very small, and in some instances are standing thickly where sown in the open, it is very advisable to carefully lift and prick-out the strongest in a warm position in the open, and the weakest into boxes, placing these in a cold frame for a few days, small plants being almost invariably destroyed by insects. Those who are without plants should sow seed at once, and treat as advised in the case of Cauliflowers. Potting-off, however, is unnecessary, as Lettuces can be readily moved from boxes or beds. The Early Paris Market and Suttons' Brown Forcing are quick-growing Cabbage varieties, and if seed of All the Year Round Cabbage and the Paris White Cos be sown at the same time the supply will be maintained.

*Peas.*—The earliest sowing of these ought now to be made on the first favourable opportunity. Nothing, however, is gained by sowing very early this season owing to the saturated state of most soils. In very heavy soils if seed must be sown it is advisable to shovel out the drill, working in some fine light soil below and above the seeds. Those who have the convenience are advised to sow seed of an early variety in pots or boxes as recently advised in the pages of this Journal, or they may sow in boxes with the fine soil divided with strips of brown paper. In four boxes 2 feet long and 18 inches wide sufficient Peas may thus be grown to plant a few short rows equal in length to about 12 yards. From these rows good early pickings may be obtained. The seed of the successional crop to be sown on the first favourable opportunity, and if possible near to where those raised in a little heat are to be planted. Place the rows of such varieties as William I., Ringleader, Sangster's No. 1, Caractacus, Dickson's First and Best, 3 feet apart, and between these either plant single rows of autumn-sown Lettuces or sow rows of Spinach. Stakes are not absolutely necessary for Peas, though they are to be preferred in small gardens. If they are to be grown without stakes the soil should be rather poor and firm, and the seed be sown thinly in drills 30 inches apart. Any of the above varieties are suitable.

*Broad Beans.*—It is also the proper time to sow for an early crop of these. The variety recommended is the Early Longpod, and the seed of this may be dibbled-in in lines 2 feet apart and 4 inches asunder in the lines.

### HOTBEDS AND FRAMES.

Those who have fermenting material and deep box frames or pits suitable for Potatoes should at once commence forcing. The fermenting material being well prepared may be made into a bed about 3 feet deep at the back, with a good slope to the front. Place on frame and lights, and if in the course of a few days the heat is found to be moderate—that is to say, if the trial stick inserted when the bed was made can be comfortably borne in the hand, the soil, which should be light, may be placed on to a depth of about 9 inches. The sets are generally sprouted in gentle heat to gain time, and where this is done they should not be planted till the soil of the bed is warm. Open good drills up or down the bed about 15 inches apart (usually three drills to a light), and 6 inches deep. Rub off all side shoots, leaving only the strong central sprout of the sets, and press the latter into the drills about 8 inches apart. Earth over with the hand to preserve the Sprouts, level the surface of the bed, and sow seed of an early Radish thinly and rake it in. The frame may be kept close till the latter has germinated, when air should be given on all favourable occasions more or less according to the external temperature. Cover the frames during the night with mats or litter. Suitable Potatoes for forcing are Veitch's Ashleaf, Mona's Pride, and the old Ashleaf. The Radishes (none being better than Wood's Early Frame and the French Breakfast) will be pulled before much growth has been made by the Potatoes, and both crops are profitable.

*Carrots.*—A shallow hotbed is sufficient for these, and two lights will grow a good quantity of sweet and tender roots. If the frame is either deep or shallow it is advisable to firmly fill it to within 6 inches of the top with the heating material, finishing off with fine sandy soil. The shallow drills for the seed may be 8 inches apart, and between these a row of early Radishes may be sown. One of the

Early Horn varieties of Carrots should be sown, and the crops will not be injured by the Radishes.

## THE BEE-KEEPER.

### THE STEWARTON HIVE.

THOUGH much has been written about the Stewarton hive, and though it has for many years been strongly recommended, very few bee-keepers have seen it, and fewer still understand the principle of the hive or its mode of management. About forty or fifty years ago Mr. Nutt introduced and recommended the collateral box hive. It did not answer to his representation and speedily fell into disuse. The Stewarton hive is not likely to follow a similar course, for those who use it and understand its management find it succeed, and some think that it is unequalled. This is true in one sense certainly—viz., that it is unlike all other hives in construction and mode of working. It is unlike the bar-frame hive, as no alterations or improvements are sought or required, whereas the bar-frame hive is only advancing to perfection. Last year Mr. Anderson of Dalry reported in this Journal that a Stewarton hive and its swarms rose in weight to a gross total of 481 lbs. Such success is enough to commend the hive to the consideration of apiarians of every class.

It is difficult to give a comprehensive and adequate description of the Stewarton hive. It is made of wood, in six separate parts, 14 inches wide, and octagonal in shape. The three bottom boxes when placed on one another are called breeding boxes, and are each 6 inches deep. The second three boxes, 4 inches deep, are honeycomb boxes or supers. All the six boxes constitute one hive, and when they are all in use a Stewarton hive is 30 inches deep or high, and is in this state first-class for work. Every honey season for the last fifteen years we have had records of the results of the Stewarton hive, and they have been most satisfactory and encouraging.

All the boxes, both breeding and honey boxes, have bars across their tops, and are without lids or crowns. This is their great peculiarity. When two or more boxes are placed together slides running in grooves are pushed between the bars of the topmost box, and these with the bars make the crown of the hive. If the hive is eked from below the slides remain in the topmost box, but if eked at the top by giving it one or more honey boxes the slides are withdrawn from the breeding box and run in between the bars of the top honey box: the slides of course must always be used in the topmost box. Let the reader observe that when all the six parts of the hive are buttoned together we have a house or hive six storeys high without separations or complications—without floors and partition walls. The bars of the boxes are thin and hardly form a separation between the boxes; the bees can travel from the bottom to the top throughout the whole breadth of the hive as readily as if there were no bars. The utmost freedom for work is given in a Stewarton. The Nutt hive had what the Scotch people call a "butt and a ben," and the bar-frame hive has in supering a kitchen and an attic; but the Stewarton has not a butt and a ben, neither has it a room below and a room above with a staircase and doorway between. A Stewarton hive is really a great workhouse and storehouse united without complication or separation. This arrangement is admirable, and facilitates indoor labour.

Some advocates of the Stewarton hive hold that one of its great advantages consists in its power of preventing free access from breeding boxes to honey boxes, especially of the queen. Slides employed in the centre of the hive, between breeding boxes and honey boxes, it is said prevent the queen going into the supers to lay. If one or two slides are kept out, at the outside combs, we are told that the bees find their way to the supers with honey, but the queen does not with her eggs. This statement has no weight with me. If the queen wishes to go to the super she would take the roundabout way as well as the bees; and if the bees resolve to set eggs in the honey boxes of Stewarton hives they would pare down the honeycombs to the proper thickness of brood comb, and take eggs from the bottom boxes, carry them aloft, and set them there, the working bees being the prime actors in this matter. The bees of a Stewarton hive are wintered in two breeding boxes. As soon as these are filled with bees in spring a third breeding box is given below, and when the third box is full supering commences by using the honey boxes above. In autumn the honey is taken and the bees confined to two of the three breeding boxes. This hive is meant to be managed on the non-swarmer principle. In every

good season for storing honey beautiful octagonal supers taken from Stewarton hives are exposed for sale in the shops of Glasgow.

This hive can be managed on the swarming system of management as well as any other hive, and probably as experience is gained the swarming system will be most followed where Heather is available. The readers of this Journal would notice that the grand result of a total of 481 lbs. from a Stewarton hive was reached through the swarming system of management. Though I do not use the Stewarton hive, and though I know well that straw is a better material for hives than wood, especially in winter, I like to speak well of this hive, which has done, and is likely to do, excellent work; and I shall be pleased if the Stewarton hive becomes more extensively known.—A. PETTIGREW.

### CALENDAR OF OPERATIONS IN THE APIARY.

#### MARCH.

IN our fitful climate temperature and other conditions vary so much that the advice given in books, though wise and right, perhaps, for the average, may be wide of suiting the particular season through which we are passing. I purpose, therefore, giving monthly some hints with the object of guiding the inexperienced, and preventing the advanced from overlooking now and again matters, which if not done to time can often not be done at all to any purpose. We have passed through a very cold period, during which the bees have been long confined to their hives, and so soon as the wind shifts and the thermometer rises to about 50°, permitting our bees to fly freely, we should overhaul our stocks to ascertain their condition, and supply whatever may be found to be essential.

FLOORBOARDS of skeps and frame hives both should be cleared of wax *débris* thrown down during the uncapping of honey cells (to secure their contents for food) during the winter, as this *débris* holds moisture, and would if unremoved give hereafter a secure nidus to the wax moth. Dead bees must also be cleared out, but if these be found in any considerable number we must suppose that our hives or our methods are at fault. Beyond here and there a stray bee no dead are found in my stocks, except in one case where I removed about one-third of a pint on Saturday, February 26th, this arising as I feel sure from the driving snowstorm of January 18th, as the mouth of the hive had only the ordinary slip door and faced direct east. FLOUR CAKE\* will now be useful if given in the feed hole of skeps or under the quilt of frame hives. Those who possess stocks in skeps without an opening above suffer a disadvantage which may be overcome thus:—Take a piece of flat thin board about 6 inches square, and cut a round hole in its centre  $1\frac{1}{2}$  inch in diameter, and put over this a square of perforated zinc with fine holes. Add a hole at each corner for a screw, of which four long ones will be required. Arm yourself now with a roll of brown paper about 1 inch in diameter and set this smouldering. A roll of corduroy will be even better. Now proceed to cut with a sharp knife the necessary hole in the skep, keep your bees in check with the smoke, and proceed quietly, when you need fear nothing; cut your hole cleanly, remove all ragged pieces, and now put a ring of clay previously made ready round the hole. Over this press your board and turn your screws into the straw. You will thus get a convenient little stage for a super and all facilities for feeding. If you have no clay use dough, but be careful to prevent all leak of hot air between the board and the skep itself, as such would reduce the prosperity of the stock considerably. An inverted bottle with or without muslin over its neck can now be used; but when the bottle is not on, cover the zinc with some thick pad for a reason which the necessity for the clay explains. In giving liquid food it is desirable (unless the very slow method is followed) to put the bottle on at night and remove it in the morning. Stocks in frame hives may at this time be most advantageously fed with combs of sealed store put in reserve in the autumn when the bees had their frames reduced in number. In order that these frames may stimulate to breeding, scratch the sealing of the honey with a pin (four or five scratches on a comb), when the bees will remove the contents from every cell the cover of which is injured, and this will act upon the stock as though store was being gathered in the natural way.

Contract the frame room rather than expand it for stocks in frame hives unless, indeed, they are very strong. Their greater heat will promote breeding, and secure an army of foragers by the time honey begins to flow (the very matter upon which almost all hinges).

ARTIFICIAL POLLEN may be given now with the greatest advantage when the weather admits of free flight. Pea flour is more useful than Wheat flour, but either will do. Place the artificial pollen in trays or boxes, or inverted skeps, slightly covering it with chaff, or sprinkling it very thickly upon loose shavings. It will require renewal during the day if the bees take it well. Expose it to the sun, and screen from wind and rain.

Warmly cover above their frames every stock. The foolish idea that bees do as well if poorly as if thoroughly protected can only be held by those who have never seen the results of really good management in this direction.

\* The recipe for flour cake has been previously given. It consists of sugar boiled carefully with very little water. Into this flour or pea flour is stirred, when it is poured into moulds to set.

Snow with sunshine is now a greater occasion of risk than during the dead of the winter. The bees are more earnestly looking for a chance to be abroad and the sun rays are stronger. Shade the fronts of the hives, or make and fix the porch I recently recommended, which will save from this and other troubles.

Borage may be sown now along the hedgerows, and will, perhaps, thus permanently establish itself to the great advantage of our bees. Sunflowers may also have a spare patch devoted to them, when they will help us greatly in our efforts to promote autumn breeding, as their natural pollen furnished late will, together with our syrup, keep our bees well up to work, and these same Sunflowers to those who may happen to be poultry fanciers furnish an abundance of seed of which young chicks are extremely fond. QUEEN WASPS if the weather grows warmer should now be looked for; and since each queen starts a nest and may possibly become the progenitor of a whole horde of pests, pains should be taken to destroy them. They can often be disabled by the finger popped upon them as they are filling at our syrup bottle; but failing this bring them down with a garden syringe, and then destroy them. Hives should now be got into readiness. It is my plan to keep a few in excess of my wants, and at this time to change my stocks into those that are clean, dry, newly painted, and fit to stand for a long period without going into dry dock. The dirty ones then, in the absence of the bees, can undergo any necessary renovation.

The one necessity for March is *promotion of breeding*, and regular, slow feeding; artificial pollen, warmth, and crowding where possible, will be found to be our right-hand assistants.—FRANK R. CHESHIRE, *Avenue House, Acton.*

#### TRADE CATALOGUES RECEIVED.

Edward Webb & Co., Wordsley, Stourbridge.—*Illustrated Catalogue of Farm Seeds.*

James Dickson & Sons, 108, Eastgate Street, Chester.—*Catalogue of Farm Seeds for 1881.*

Ellwanger & Barry, Mount Hope Nurseries, Rochester, N.Y.—*Descriptive Catalogue of Select Roses.*

W. Lovell, Weaverthorpe, York.—*Select List of Strawberry Books.*

Francis and Arthur Dickson & Sons, Chester.—*List of Select Farm Seeds.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Address (H. B. and R. I. L.).**—Mr. Adie's address is 15, Pall Mall, London S.W., from whom you can obtain the particulars you require.

**Transplanting Box Edging (H. B.).**—Just as fresh growth is commencing in the spring is a good time for replanting Box edging. This is usually about the latter end of the present month or the beginning of April, according to the season and district. You may cut the dead wood from your Roses at any time now.

**Apples for Succession (J. S.).**—It is impossible for us to place the varieties you have named in the order of merit, as all of them cannot be judged by any one standard. Each have qualities of their own, and all the varieties are worthy of cultivation and suitable for your district. Instead of attempting to arrange them in the order of merit we will place them somewhat in the order of ripening. *Dessert*—Irish Peach, Devonshire Quarrenden, Cox's Orange Pippin. *Kitchen*—Lord Suffield, Keswick Codlin, Cellini, Ecklinville Seedling, Warner's King, and Dumelow's Seedling; but the two latter are practically in use during the same period. As a rule Apples are better adapted to the bush than the pyramid mode of training.

**Zonal Pelargoniums Charles Smith and Charles Schwind (P. R., Wigan).**—You variety described on page 150 last week is probably Charles Smith; as the name was not written plainly, and as the description applied equally to Charles Schwind, we concluded it was that variety. Mr. C. E. Pearson of Chilwell informs us that "the two varieties are distinct, though both crimson, Charles Smith being sent out one or two years before Charles Schwind, which is a shade darker in colour than the former. We have not tested them for winter blooming, but for summer work they are superseded by Rev. A. Atkinson for bedding, and Henry Jacoby and Dr. Orton for pots."

**Cinerarias (E. W. B.).**—On a first glance at the sprays we thought the plants had received a check or been infested with insects; a closer examination, however, indicates that the growths are clean and healthy. The flowers are amongst the smallest we have seen, and if they fairly represent the "strain"

we must pronounce it worthless. Your plant is *Helleborus foetidus*; it is very hardy, and useful for furnishing vases in the open air during the winter.

**Plants Around a Pump (R. N.).**—You will scarcely find a more suitable plant than *Lysimachia nummularia* for the purpose named, as it grows quickly and would thrive in such a position, while few other plants would live.

**Disbudding Vines (J. M. B.).**—You pruned your Vines correctly, and you are adopting a wise course by deciding to have the lateral growths thinly disposed on the main rods. Overcrowding of the spurs and laterals is a fertile source of small imperfect foliage and small fruit. With the Vines 4 feet apart and their growth vigorous we should have the laterals about 18 inches apart on each side of the rod, an inch more or less not being important. We should not, however, disbud the young Vines at once to the extent indicated, as an accident is always liable to occur during the early stages of growth, and to lose a lateral after the final disbudding would leave a gap that would not be easily filled afterwards. The laterals may be left for a time at 9 inches apart, indeed during the present season, letting them make all the growth possible without overcrowding, as this will encourage root-action. You may remove the superfluous laterals at any time where there are signs of overcrowding, or in the autumn.

**Hyacinths in Glasses—Offsets (Amateur).**—They are of very little use for pot culture next year, yet with care the bulbs may produce small spikes that are acceptable for cutting. Immediately the flowers fade the spike should be cut, the plants being removed from the glasses and potted in very light compost, such as leaf soil and cocoa-nut fibre refuse, and placed in a cool frame to perfect good foliage. They should be watered regularly until the foliage shows signs of decay, and then less frequently. With good foliage and light to mature it the bulbs may be of some service another year, four or five of them being placed in 5-inch pots to produce miniature spikes for cutting. If good foliage is not produced this year and kept healthy as long as possible flowers cannot be expected next year. The time that offsets of Hyacinths require to become flowering bulbs depends entirely on the culture that they receive. In poor or heavy soil and a cold position they may be four or five years; in rich light soil and a warm position they arrive at a fair flowering stage in half that time. We are unable to state the cause of your Tulip bulbs withering; we have known them wither if the pots and plants have been covered too long with ashes or other material that was placed over them in the autumn.

**Tuberose (Salepian).**—We cannot better reply to your questions than by quoting the remarks of Mr. W. Taylor which appeared in vol. xxxviii of this Journal. "The imported bulbs are received in December or January, when they are at once potted singly in 6-inch pots and plunged where they can have the benefit of bottom heat to start them into growth. After they once start fairly they can be grown in a low temperature and without bottom heat; and when all danger of frost is over, if they are not wanted to flower early, they can be placed in a deep cold pit and be merely protected from the worst of the weather till the flowers commence opening, when they will be improved by being taken into the greenhouse. Plants so treated will generally flower some time between July and October. After flowering most people throw them away as useless. This is quite a mistake, as I will endeavour to prove. Mine are at once shifted into 7 or 8-inch pots without disturbing the ball, using a good rich compost consisting of turfy loam with a little decayed manure, a few half-inch bones, and a little charecoal. They are again placed in a warm house and soon commence throwing up shoots, one of which only is left to grow, and it soon forms a new bulb on the top of the old one, which will not fail in its turn to send up a good strong flower stem. I have no doubt that the small shoots which are taken off would, if liberally grown, soon make good plants. I have already grown some of them this way, and was not aware that it was an uncommon thing to do; but I have kept no notes concerning the time it takes, yet I am under the impression that some of them flower again during the following winter. I will try to make my meaning plain. The Tuberose shortly after flowering generally dies quite back, leaving nothing visible above ground excepting the top of the bulb. This period should not be hastened by removing the flowerstem or withholding water while there are healthy leaves on it, but it should be allowed to die back naturally, and water should not be altogether withheld, even when there is no visible growth. I pot them at this time without disturbing the roots or any part of the plant, and place them in a little warmth. They soon commence growing by forming several little bulbs on and near the top of the old one. If all were left of course they would grow weakly; one only is left, and it rapidly enlarges, having the roots of the old bulb to supply it; the rest are picked off with the finger and thumb, and may be potted and grown in the same way as little *Amaryllises*. I have succeeded best so far with the bulb which remains on the top of the old one. Probably the young bulbs would take two years to grow them to a flowering size, but I have kept no memoranda on this point."

**Sea Gulls in Gardens (Heather Bell).**—Although the narrative of your bird is interesting the great pressure upon our space prevents us publishing it. We have had long experience of the utility of gulls in gardens, as they devour worms, slugs, grubs, and insects with avidity. The birds also become very tame, and attach themselves to those who feed them, for they require feeding during very dry weather in summer, and especially during severe weather in winter. When the frost is very intense it is desirable to afford them some shelter. We are intimately acquainted with one of the few "homes of the gulls" in England. The birds arrive in early spring, lay their eggs on the margin of a secluded piece of water, rear their young, then migrate to the sea, living on fish during the winter. In the breeding ground to which we allude there are countless thousands of these pretty birds (the black-headed gull), and they are of great benefit to the district, as for some miles around they are in every field in which ploughing is being done, every furrow being crowded with them within a foot or two of the ploughman's heels. From those fields they must take millions of grubs and insects. When kept in gardens they search diligently after similar food, and do not in the slightest degree injure any crops. Suitable food for the birds during winter is raw liver, and scraps of refuse meat of almost any kind.

**Dressing Trees with Brine and Soft Soap (F. S.).**—The following are the instructions in the "Gardeners' Year Book," to which we presume you refer:—"During the dormant months of winter every means should be resorted to for destroying the eggs and larvae of insects that are injurious to the trees during the period when vegetation is most active, and as these always harbour on the bark and in its crevices there is no season of the year when their haunts can be so easily invaded and the enemy dislodged as now. For this purpose, then, remove all filth and excrescences from the surface of the bark, such as the old scales, moss, and lichens, with a blunt scraper, such as an old knife or a piece of hoop iron, for it is on these that the pests mainly harbour; then wash the stem and branches well with a mixture of brine and soft soap, applying it with an old painter's brush, and rubbing it well into the crevices. Walls also, and particularly old ones, are capital harbours for insects. Where they are so old as to require fresh pointing this should be done without delay; and all walls that are not absolutely new, or which in any way afford shelter to insects, should also

receive a thorough washing of the same mixture as the trees. In some of the washes lime is recommended; but where the walls are of brick, or even of nice clean stone, those whitened patches always look unsightly in a garden, and we do not attach so much importance to the efficacy of the action of the lime as to consider it an essential ingredient; soft soap and brine are both sufficiently injurious to insect life, and after their application they leave no unsightly effects behind them." The remarks apply to the stems and branches of old orchard trees that are often encrusted with moss and lichens; they also apply to similar portions of old trees on walls, and to the walls themselves, not to the spurs and fruiting parts of the trees, to which the brine would probably be injurious at this season, when the buds show signs of swelling. Brine is formed by placing sufficient salt in water to enable an egg to float in it, and a quarter of a pound of soft soap dissolved in a gallon of water will be the right strength for mixing with the brine for dressing the mossy trunks of old trees and the surface of the wall; but we do not advise to apply such a strong solution of salt to the younger growths or fruiting portions of the trees.

**Raising Cucumbers** (*C. C. Donaghy*).—The same frame in which you raise the plants will do for their aftergrowth, but it is more economical as regards manure to raise the plants in a smaller frame. It is not necessary to sink the beds below the level of the ground. The materials for making up the beds should be thoroughly well worked by being turned over four or five times, shaken together well and mixed, and if dry and husky be thoroughly well watered at the first two turnings as the work goes on. The lumps should be broken up, and the short mixed with the long, until the whole mass has one uniform appearance and is nearly half decayed. The size of the beds depends on the season. In February 6 feet high at back and 3 in front; in March a foot less will be sufficient. A dry bottom is desirable, and the materials well put together, shaken up, and beaten down well with the fork as the work goes on, treading all round the sides occasionally, and the bed should be always 6 or 8 inches wider than the frame all round. As soon as completed put on the frame and lights. When settled, and all has become sweet and healthy, the hillocks of earth may be put on for the young plants to be placed in; but before the hillocks are made—particularly in the early season, when the very strong beds cause some danger of burning—some preventive measures must be adopted. Almost every dundged Cucumber grower has his favourite way to prevent this occurrence. Some pave the bottom of the hillock with six or eight bricks; others with a thick twist of straw or some hayhands, over which 3 or 4 inches thick of cow dung are placed of about the substance of mortar; others, again, remove a little of the centres, and place therein a good thick turf with the grass side turned downward, and on this a good thick paste of cow dung. Whichever method is adopted the hillock must be about a bushel of rich earth prepared for the purpose, and in a cone shape, so as to bring the plants within 6 or 7 inches of the glass. As the roots grow round the hillock they should be covered with a handful or two of earth, and if all goes on well the hillocks will very soon require to be extended, and the plants stopped and pegged down. The seed should not be sown until the heat of the bed is sweet and healthy, to which state it may be hastened by its surface being stirred once or twice daily and watered, plenty of air also being given. The best material to put on the seed bed to plunge the pots or pans of seeds in is old tan or well-decayed dung or leaf soil, which may be run through a very coarse sieve. With this material the bed may be covered, or any part of it, to any thickness, to suit the purpose intended; and its being sifted makes it the more pleasant to handle, either for raising the plants nearer to the glass or lowering them. The seeds may be sown either in small pots or in pans, and the seedlings to be moved from one to three plants in a pot. If sown in the pots, so as not to need shifting, the pots may be crocked, and a little better than half filled with earth, and three seeds in each covered half an inch deep. When the plants are up they may be thinned either to one or two in each pot, and as the plants advance in height so the pots may be filled up with rich light earth, which should be kept in the frame for the purpose; also, a small pot of water should be kept in the frame for moistening the earth or sprinkling the plants when required. The plants should be kept within 3 or 4 inches of the glass. As soon as the young plants have formed two rough leaves they should be stopped. You must maintain a night temperature of 65°, with the lights propped up half an inch or so at the back, the glass being covered with mats if needed. The day temperature with sun may be 85°, ventilating with great care. Cold draughts and cold water are fatal to young Cucumber plants. Seed may be sown any time during the present month, a suitable temperature for plunging the pots in being 80° to 85°. Telegraph is a very useful variety.

**Transplanting Carnations** (*Idem*).—If you require a mass of flowers for cutting the plants may bloom in their present position. If you wish to have them distributed in your borders you can take out every alternate plant from the beds, retaining as much soil about the roots as possible, and replant carefully at any time during the present month when the weather and soil are favourable. If the plants are not removed they will not need top-dressing, but if a portion of them are taken from the bed the spaces they occupied should be covered with fresh soil and manure.

**Repotting Haresfoot Fern** (*Idem*).—Two-thirds of turfy peat, one-third of turfy loam, and a liberal admixture of broken charcoal, will form a suitable compost. Drain the pots thoroughly, and see that the soil in which the plant is now growing is not dry when removed. Towards the end of the present month, or when fresh growth is commencing, is the proper time for potting.

**Grafting Rhododendrons** (*Idem*).—The usual plan is to have the seedling stocks in pots, and graft them either at the present time in heated pits or in August in cold frames, or inarching may be done in September in the open air.

**Names of Plants** (*G. O. S.*).—*Rusens aculeatus* or the Butcher's Broom is the name of the plant of which you enclose sprays. It not only forms a good barrier against dogs and cats, but grows well under trees. Your notes are turned to much better account than the one you suggest. We are always glad to hear from you. (*Constant Reader*).—1, Totally insufficient; 2, also very small, but apparently *Veronica Andersoni*. (*C. T.*).—*Fraxinosa eximia*. (*S. B.*).—1, a good form of *Cypripedium insignis*; 2, *Tillandsia zebrina*; 3, *Blechnum boreale*. (*H. Shaw*).—*Acaelia dealbata*.

**Bees Covered by Snow** (*J. S. Cairnie*).—You ask whether it would be wise to remove the snow from your hives which have been now buried beneath 4 or 5 feet of it for approaching two months. The snow thus covering your hives is a great advantage to your bees—*i.e.* if the snow is light and fleecy it secures for them a perfectly still air, and thus saves them altogether from one main loss of heat—*viz.*, that occasioned by chilling draughts entering the hive mouth with every puff of wind. The snow will have been melted away from immediate contact with the hive entrance, and through it (the snow) quite sufficient air will percolate into the space thus occasioned to supply all the wants of the bees. In Russia it is quite common for hives to stand much more deeply buried than yours, and the bees thus situated are protected admirably

from the intense rigours of the winter. Do not disturb the snow, then, until a thaw begins to solidify it, as then the water running through it would work damage and it would become impervious to air; but in removing it cause as little jar as possible, and shade the hive mouth carefully for a time lest the inflow of light should tempt the prisoners out to their destruction.

#### COVENT GARDEN MARKET.—MARCH 2.

OWING to the frost trade keeps very quiet. The bulk of hothouse Grapes is now arriving very much shrivelled, but fine samples are realising high prices.

#### POULTRY AND PIGEON CHRONICLE.

#### THE MANURING AND IMPROVEMENT OF PASTURE AND PARKLANDS.

GRASS LAND management is a subject of far more importance than it has ever been before, for in consequence of the general depression existing in connection with agricultural pursuits large tracts of land have been thrown upon the proprietors' hands—much of it in an impoverished state and foul condition. Upon various estates it will require all the practical knowledge and judicious treatment which the agent or home farmer can command to meet such an emergency as now prevails; in fact, some fields are actually run to waste in those instances where the owners cannot find capital sufficient to cultivate and lay down the land to permanent pasture. The last is certainly the extreme difficulty, but in case we look at it fairly under the heading of our subject there is no reason why land run to waste cannot be brought into profit without the expense of tillage and cultivation, supposing the water passes from it freely and the fields are level enough to bear mowing and the ordinary treatment of pasture land. Although we have named an extreme case we have known large areas of land thus situated, which have been manured and renovated without tillage, and the letting value so much improved that it has been comparatively easy to find a tenant.

If the home farmer will refer to the articles in this Journal dated the 24th and 31st of January, 1878, pages 75 and 95, under the heading of "Management of Pasture and Parkland," and also to the articles under the heading of "Laying Down Land to Permanent Pasture," February 5th, 12th, and 19th, 1880, pages 105, 126, and 145, much information on the general subject will be found. We have named these references because we do not intend on this occasion to examine the whole subject again, but

merely to introduce various practical and theoretical statements which may be considered supplementary to former contributions. We are led into this in consequence of the increasing interest in the subject taken by landed proprietors. Nothing has ever been written of more importance in farming than the papers lately given by Mr. Lawes in the *Agricultural Gazette*, which make us acquainted with various theoretical and practical points. It is, however, a very wide subject, and on which much diversity of opinion necessarily prevails.

In reference to the manuring of old permanent pastures, and those recently laid down or intended to be laid into permanent grass land, we should first understand the difference in the fertility of old pastures and that recently formed out of arable land. The remarks of Mr. Lawes are not only interesting but very instructive, and upon which we are induced to place the greatest reliance by reason of his experience and long-continued experiments carried out at Rothamstead with intelligence and perseverance without regard to the outlay of capital. Taking all the matters into consideration Mr. Lawes stands alone in his position in this country in his ability to carry out anything by way of experiment which may be necessary for furnishing evidence for the farmer's guidance, and upon which he may rely with unlimited confidence. Mr. Lawes states, "Practical knowledge has decided that when a field of permanent pasture and one of arable land lie adjoining, the former contains a larger store of fertility than the latter. Practice has equally decided the point that, by the conversion of pasture into arable land, these stores of fertility can be made available for the production of corn, roots, &c.; and further, on the other hand, that the converse process of forming a permanent pasture from an arable soil is a work of time: but the duration of the period before that newly laid down will equal the old pasture in character must depend altogether upon the nature of the soil and climate of the locality, and the treatment which the land has received. To these facts I propose to add some further information which may be of service at the present time, when the conversion of arable land into pasture is exciting so much interest. At Rothamstead—in addition to the permanent pasture in the park, which has probably existed as such for centuries, though its exact age is unknown—I have from time to time laid down land to grass at intervals commencing from forty years ago up to 1879. I am therefore in a position to furnish considerable evidence on the subject, so far as my own land is concerned. The old pasture under experiment in the park, after the removal of twenty crops of unmanured hay, would probably contain more nitrogen in the first 9 inches from the surface than any of the land laid down by me, and nearly twice as much as would be found in the arable land. I may, however, possibly be able to convey the impression which I wish to make by an illustration. How great is the accumulation of manure ingredients in the soil in some cases we may gather from an experiment at Rothamstead, where, upon a plot of old garden soil, the removal of two or three crops of red Clover annually for a quarter of a century, without any fresh application of manure, has not yet exhausted the stock already existing in the soil. Again, upon part of the permanent Wheat field 14 tons of dung per acre have been applied annually since 1844. This would amount in round numbers to 500 tons, containing about 7000 lbs. of nitrogen, equal to about 8500 lbs. of ammonia. Of this the crop may have removed one-fourth, a portion has been lost, and another portion has become part of the capital stock of fertility in the soil. So large is this capital and so tenaciously is it held that probably a century of unmanured cropping would not entirely exhaust it, and yet it is probable that the nitrogen accumulated in the first 9 inches of the soil is less than that contained in the first 9 inches of the unmanured pasture. Your correspondent, in his very interesting history of the Rothamstead grass experiments, refers to the fact that I have to produce 8 or 10 tons of grass roots in every acre of new pasture. In addition to this I may here add that I shall further have to accumulate in the soil about a ton of nitrogen before my new pasture will be equal to the old."

We desire to call the attention of the home farmer to the way in which the facts above stated show the necessity of treating differently the old and new pastures. In the old pastures, if fed off by cattle eating decorticated cotton cake, little else would be required; whereas the new pasture should not only have the cotton cake consumed upon it annually, but liberal dressings of yard dung and ammoniacal manures like guano and nitrate of soda, as well as manures containing the phosphates, should be applied yearly. This should be done without reference to the requirements of the grasses for the time present, but enough to be continually acting upon the roots of the grasses until they attain to almost a solid body like roots of good old pasture; or, in other words, making such an investment on the land that the capital or

stock of manure should be equal to the formation of a full plant of stock grass roots, in order to its permanent establishment. In previous articles relating to laying down and maintaining permanent pasture we have not stated the time which it would take to bring new pasture into a state when it shall be equal to the old, nor can it be stated as a question of time. What we have most strenuously contended for is a most liberal and abundant supply of manures, not only at the time of seeding but annually afterwards, so that the seeds when properly sown may afford a luxuriant growth sufficient to make the pasturage worth the expenses of manures until it can be ranked with the old pastures in turf and production. This will depend upon a variety of circumstances other than manuring, such as the soil, climate, judicious feeding, mowing, and general management, also the growth and decay of the roots of the grasses. Our next notice of Mr. Lawes' paper will comprise a quotation wherein he practically describes the herbage produced upon the best grazing lands of Leicestershire and their value, from which we shall endeavour to draw certain important conclusions which may well direct us in the choice of seeds of grass, Clovers, &c., for laying down or renovating our new grass lands; in fact, we have various comments to make upon the subject of great importance considering the present condition of agriculture.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Tillage has been well nigh impossible during the greater portion of the month of February, and therefore compared with ordinary or average seasons this and seed time is very late even on the driest soils. The seeding of Barley as a second corn crop may be attended to, but should depend almost entirely upon the land being clean and free from couch grass. It is, however, not advisable to sow Barley after Wheat when the latter has been sown by once ploughing out of lea, unless an autumn fallow has been made, for on the loamy or mixed soils the land would be too heavy and close for the growth of Barley with success. In a season like the present spring culture could be done until the seed time, which cannot be delayed by cultivation without the risk of a late crop or the land becoming too dry for the seed to vegetate with regularity. We therefore advise that land be selected for early seeding with Barley after Wheat or other crops which had been prepared for by a fallow. Upon very light and dry soil Barley may be sown as soon as the land becomes dry on the surface—land where roots have been fed off by sheep. Upon loamy and mixed soils we would sooner sow drege, as it is much surer to yield a profitable return. There is one preparation for Barley which is really a very good one upon ordinary soils, especially after such a frosty winter as we have experienced—namely, the land which had borne a crop of Mangolds last year; it is, however, a common practice to sow Wheat after Mangolds as soon as the land is cleared of the crop. We prefer to plough in the Mangold leaves, and lay up the land as fallow for the winter months, after which no land upon the farm will be more likely to yield a full crop and malting sample of Barley if sown at the first fine weather which happens in the spring. Such land, too, will require but little labour; one scarifying will be sufficient before seeding, and prove a much better preparation than ploughing. Another advantage we have found that red Clover is likely to plant well after the Mangold crop, whether seeded in Barley or Wheat, especially if the land is not ploughed in spring, and the fine weather-beaten surface maintained and retained by the use of the scarifier or horse-hoe only, which makes the best seed bed the Clover can have.

*Hand Labour.*—The work in the woodlands and hedgerows should now be nearly concluded in order that the men may be employed in work connected with the tillage, manuring, and seeding of the land. The plashing of hedges, banking, and ditching should now be completed. The outlets of all draining work, whether in the pastures or arable land, should be attended to whilst the ditches are being scoured. Finding these outlets is often a matter of much uncertainty, especially upon those estates where the home farmer has no map of the draining or plans of reference to assist him, and it is at once shown the disadvantage of this when strangers and new labourers are employed in such work. In some meadows where draining has been done in peaty soil there will occasionally be collections in the tiles of a red ferruginous matter, which if allowed to collect undisturbed will become a hardened mass and entirely stop the drains. Upon such soils where we use iron rods with a swab at the end, so that when introduced into the tiles twice a year, in March and October, they may be scoured and kept open, and as we have the iron rods made in certain lengths which can be screwed together we are enabled to scour and free the tiles for a considerable distance within the outlets. We recommend this system, otherwise these drains will require constant repairs by taking up portions and relaying, which proves very expensive, especially if no map of the draining is available. The crops of Swedish Turnips are nearly all so much injured by the frost that they will be of no use after another ten days or a fortnight, excepting the late-sown pieces, which are mostly sound and uninjured, being in full growth and vigour when the frost commenced. If allowed to remain undisturbed in the land and ploughed in, although they may be quite decayed, they will manure

it sufficiently to insure an average crop of Barley or Oats; the former, however, would answer best, the land not having been trodden by sheep will be light and favourable for that grain. The loss of the Swede crop should induce the farmer to anticipate and provide for any deficiency which may occur; in fact, on many farms if the months of April and May should prove dry and cold the situation in some cases may prove a disaster in respect of the purchased food required to carry a breeding flock on to maturity. As the time for planting Potatoes is arrived the selection of the early sorts is of far less consequence than the later varieties, because the former are usually lifted and sold before the disease appears. The late sorts which have been proved as most likely to resist the disease are the Champion and Magnum Bonum, but we advise that any new variety which is highly recommended should be planted for experiment, and if found sound when taken up a considerable store for next year's planting will be advisable; and this is of consequence, because all new sorts which can be depended upon are costly to purchase in a large bulk. We still recommend that when the land intended for Potatoes was not manured in the autumn or winter that artificial manures only should be used, the guano which contains the most ammonia being the best hand manure which can be used, especially if mixed with damp ashes to prevent the manure being too much scattered by the wind. In this way we have found 4 cwt. of guano per acre cast into the furrow with the sets, equal and in some respects preferable to the largest quantity of either yard, box, or town manure which can be applied; at the same time there is the advantage of being able to plant the tubers as soon as the weather is favourable, and thus avoiding the delay of the season, and the treading and tracking of the land by the laying-out and spreading of dung.

#### VARIETIES.

**THE COMMITTEE OF THE POULTRY CLUB.**—In consequence of Mr. Butler Smith having declined to serve upon the Committee of the Poultry Club there is a vacancy in that body. I shall feel obliged by nominations (which must be made by at least two members of the Club, with the consent of the person nominated) being sent to me before the 10th March.—ALEX. COMYNS, *Hon. Sec. Poultry Club, 47, Chancery Lane, London, W.C.*

**— WORK FOR WOMEN.**—It may be some consolation to Madame Lina (Geneva), to learn that in the town of Prescott, the seat of watch movement-making, that several of the large manufacturers have introduced female labour, which answers very satisfactorily. It is only, however, where machinery has been introduced that it is found desirable to employ females.

**— BATH AND WEST OF ENGLAND SOCIETY, AND SOUTHERN COUNTIES ASSOCIATION.**—At the Council meeting held at the Grand Hotel, Bristol, on Wednesday, February 23rd, Mr. Charles Edwards, as Chairman of the Finance Committee, brought up the annual statement of accounts. Having pointed out the fact that the deficiency on the year's proceedings amounted to £1154, and had been met by the sale of £1000 India bonds and from the balance in hand, he went carefully through the receipts and expenditure of the various departments, and showed the profit and loss on each. The account was approved and ordered to be printed in the forthcoming volume of the Journal. Mr. Jonathan Gray, as Chairman of the Plant Committee, presented the annual statement, which showed a profit on the Society's plant for the year of £241 6s. 8½d. Colonel Luttrell, on behalf of the deputation appointed to visit Cardiff to inspect the proposed sites for the Society's exhibition in that town in 1882, reported that the site offered for the show yard was the Cathays Park, which had been generously granted for the purpose by the Marquis of Bute, and they had no hesitation in expressing an opinion that the meeting next year at Cardiff would be exceptionally successful. Letters were read by the Secretary from the British Bee-keepers' Association and the West Kent Bee-keepers' Association, requesting facilities for an exhibition of bee manipulation and appliances at the Tunbridge Wells Show, and it was resolved that, subject to the approval of the Allotment Committee, space be granted in the yard for the erection of a tent for the purpose, on the condition that there be no extra charge for admission thereto. It was further resolved that the arrangements be carried out under the direction of the Hon. and Rev. J. T. Boscawen, Steward of Horticulture.

**— A SIMPLE TEST OF WATER IN MILK.**—A German chemist furnishes a simple procedure for testing the amount of water in milk, which can be applied by anyone. All that is required is a small quantity of plaster of Paris, say an ounce. This is mixed with the milk to a stiff paste, and then allowed to stand. With milk of 1030

specific gravity, and a temperature of 60° Fahrenheit, it will harden in ten hours; if 25 per cent. of water is present, in two hours; if 50 per cent., in one and a half hour; and with 75 per cent., in thirty minutes. Skimmed milk which has been standing for twenty-four hours, and is of 1033 specific gravity, sets in four hours; with 50 per cent. of water, in one hour; and with 75 per cent., in thirty minutes. Heat should not be applied, for then the use of the thermometer would be required.

**— PROPOSED "ROYAL" SHOW AT READING.**—The Committee of Inspection appointed by the Society of the Royal Agricultural Society visited Reading last week for the purpose of viewing the site offered to the Society for its proposed exhibition at Reading next year. The Committee, consisting of Mr. Wells (President of the Society), Sir Brandreth Gibbs, Mr. Charles Rendell, Mr. J. Shuttleworth, Mr. Jacob Wilson, and Mr. H. M. Jenkins (Secretary), went over the farm of Mr. Colebrook (Mayor), and the adjoining land belonging to Mr. Palmer, M.P., and expressed themselves very pleased with the site. Having lunched at Sutherlands, by invitation of Mr. Martin J. Sutton, the visitors inspected Messrs. Sutton and Sons' business premises, and afterwards returned to town.

**— ENGLISH CART-HORSE SOCIETY.**—The report of the Council states that the Society at the present time numbers 522 members. The receipts for the present year (including the balance at the bankers on December 31st, 1880) are estimated at £990 12s. 3d. The expenditure for the present year is estimated at £746 10s. 9d., which includes the cost of the second volume of the "Stud Book," now ready for distribution among the members. It numbers 168 stallions and about 500 mares. A considerable loss was sustained by the Agricultural Hall Company on the first show held last year; so much so that this second show would not have been held but for a subscription liberally responded to by ninety members of the Society, amounting to £342, and which was handed by the Horse Show Committee to the Agricultural Hall Company towards the prizes now offered, amounting to about £500, and to aid in carrying out the details of the present show without financial risk to the Society. The important display of horses and the large number of entries at this second show tend to prove that it is the firm desire of the members and others that these shows should continue to be held.

**— AGRICULTURAL PROSPECTS.**—Another week of dull cold weather, with snow and rain, has not improved the condition of the land, and unless we get drying winds the stronger soils will work badly. As it is, work at the commencement of March is not by any means in a forward state, and the spring must of necessity be an unusually anxious time. Reports this week are unanimous in ascribing but little damage to the young Wheats from the severe frosts; at the same time the damage to roots in the fields—and even in stacks where not properly protected—is now known to have been very great. Liver fluke is very prevalent, and where foot-and-mouth disease has occurred amongst lambing down ewes the loss of lambs is likely to prove serious. So far as the lambing season has hitherto gone reports vary, but at the best they are not very cheerful. Dry weather and bright sunshine are now what is needed for the land and for the stock upon it.—(*Mark Lane Express*).

**— EFFECTS OF FROST ON CABBAGES.**—This has been most disastrous this year. The fact is, hardly any of the Cabbage tribe will bear the touch of zero; and that, or even a lower temperature, was reached in many localities. It may be noted, however, that late Cabbages will bear far more frost than those that are earlier. The whitest, hardest Cabbages are always the most injured; it might, therefore, be desirable to sow and plant later; or two or three sowings might be made, and several successive plantings. It would generally be found the latest, though not the largest, would winter best. For general purposes there seems to be no hardier Cabbage than the Drumhead; but others are grown at times, and it would be found that leaf Cabbages winter best. Late Savoy also winter better than Cabbages. The Pomeranian Cabbage used to be grown extensively in Scotland as one of the hardiest; it is a sort of pyramidal Sugarloaf Cabbage, as different as well could be from the Drumhead; it might be planted more than as close again. Again, Scotch Kale of any sorts are much hardier than Cabbages; they are

less solid, but might prove useful food for early ewes and lambs, as well as milch cows.—*AGRICOLA* (in *Agricultural Gazette*).

## POULTRY AND PIGEONS

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 143.)

#### FORMING A STRAIN.

WHETHER the beginner adopts the first or the second course which we have indicated, the method of breeding which he must pursue will be very similar. The distinction, as we have already pointed out, will lie chiefly in the fact that in the first case starting with birds which have been already inbred to a considerable extent, he is less likely to be able to carry out the system so far without the strain deteriorating in certain points. This will render it necessary that great care be taken not to carry the process of inbreeding too far; but as birds purchased in this way may be either very closely or only very distantly related to each other, it is impossible to indicate how far inbreeding may be carried in each particular case, and this must be left to the discretion of the breeder himself.

Artificial selection is to some extent a separate process and must be dealt with separately, but the course to be pursued in regard to the first two cases being so nearly identical they may be discussed together.

Let us suppose, then, that the breeder has purchased a cockerel A and a pullet B quite unrelated to each other and as free from faults as possible. He must mate these together, and set every egg laid during the hatching season. When the progeny have come to maturity it will probably be found that none of them are really good. The breeder must not, however, be discouraged by this, as it is merely the natural result of breeding from perfectly unrelated parents. The best cockerel of the progeny must be chosen for mating with the pullet B, now a hen one year old. From the progeny of this pair the best cockerel must again be chosen and mated with B, now two years old.

In regard to some breeds of poultry this is as far as the length of life of the birds will permit the process to be carried; but in regard to other breeds and to Pigeons it may sometimes be carried a year or two further. We will suppose, however, that three laying seasons is as much as can be depended upon. The progeny of the first year's breeding being one-half of the blood of A and one-half of the blood of B, and a cockerel of this year having been mated with B, it follows that the progeny of the second year would be quarter A and three-quarters B; and upon the process being repeated the third year the progeny will be one-eighth A and seven-eighths B. A precisely similar process having been gone through on the other side by mating the three or four best pullets of the first year's progeny, which were one-half A and one-half B, with the cock A, and so on for the three years, it will be manifest that at the end of the three years the breeder will have the two original birds A and B, which will as a general rule be now unfit for further use, and a number of birds some of which are seven-eighths A and one-eighth B, and the rest of which are seven-eighths B and one-eighth A. He ought also to have reserved some birds of the previous year which are three-fourths A and one-fourth B, and three-fourths B and one-fourth A respectively.

He can now adopt the method, which is found to be on the whole most advantageous, of mating cockerels and pullets with birds over one year old, and ought to be in a position to start four yards of good birds which are only distantly related to each other—that is to say, he can mate a cock which is three-fourths A and one-fourth B with pullets one-eighth A and seven-eighths B; he can mate a cockerel which is seven-eighths A and one-eighth B with hens one-fourth A and three-fourths B; and he can also mate a cock three-fourths B and one-fourth A with pullets one-eighth B and seven-eighths A, and a cockerel seven-eighths B and one-eighth A with hens one-fourth B and three-fourths A.

When he has got thus far he may be fairly said to have formed a strain of his own, and his subsequent course of action must follow as much as possible in the lines already indicated—that is to say, he must for as long a time as possible keep the blood of each yard distinct from that of the others, merely using the others for the purpose of comparatively fresh blood when necessary, or for correcting any point in which one yard may be deficient.

Of course these directions must only be understood as general principles to be followed so far as circumstances admit; not as rules to be fixedly adhered to in all circumstances. It may be that even though the two birds originally chosen were themselves

free from glaring faults of any sort, yet they may have inherited tendencies to such faults, which by the course of breeding adopted have been developed in the progeny. If this be so the method suggested must not be followed so far as we have indicated, but at an earlier period a bird may be selected from the other yard with a view to the correction of the fault in question.

In starting a strain we are entirely averse to the system we have seen suggested by some writers, of mating birds with faults which mutually counteract each other. For instance, in the case of Brahmas, heavy feather and vulture hook on one side, against poorly feathered shanks on the other side; but when a bird is introduced into a strain merely for the purpose of counteracting a fault in the strain, and there is no intention of inbreeding from the bird thus introduced, the same objections do not apply. In that case, a bird having developed in an exaggerated degree the point in which the strain is deficient, may with advantage be used; but we shall have more to say upon this point when we come to speak of introducing fresh blood.

We now turn to the course of procedure to be adopted where the method of artificial selection is chosen by the beginner.

Here, just as in the other two cases, it is necessary that the breeder should have clearly settled in his own mind the points which he is aiming at; and he must in the first instance choose birds which to a certain extent, however small that extent may be, have developed these points. If not, the process of artificial selection will become a most difficult, and, indeed, perhaps an impracticable one.

Here it is as well to begin with as large a number of birds as possible, so that the process of selection may have as wide a scope as possible, and that when the strain has been formed the birds may not be so closely related to each other that it will be necessary at once to introduce fresh blood. A well-known breeder of our acquaintance, who was recently starting a yard upon this principle, said to us that he always liked to have as great a variety as possible to begin with; and in this respect we quite agree with him. As many chickens as possible must be hatched and reared so far as necessary to make sure of their quality every season. From these must be selected those which most closely approximate to the standard of perfection of the breed. These again must be mated together, and the same process repeated with their progeny, only those birds being kept and bred from which have developed to some extent the points sought after.

If the number bred be large enough it will be found that after two or three years of this process the number of the progeny which are valuable will be largely increased, and when a reasonable proportion of good birds are produced the breeder may with advantage adopt the course we have advised above, and keep two, three, or four yards each as distinct as he can in blood from each other, but so far related to each other that mutual crosses may be resorted to without fear of the progeny throwing back to inferior ancestors.

#### FOOD FOR EARLY CHICKENS.

GOOD food is at all times very necessary to the well-being of young fowls. Especially is this the case in cold weather and early in the season, such as in February and March, when they have few chances of picking up anything for themselves, and ordinary summer food is not sufficient to keep out the cold, or the body in a healthy growing state. Hot food is very desirable at this time, and is probably better produced with spice than hot water. Apart from warmth, however, the food must also be strong, and in this respect few kinds are better than hard-boiled eggs chopped up and mixed with the meal. The only objection which can be offered to the use of eggs at this time is their scarcity and expense, but a remedy for this may be pointed out. As a rule not above half the number of eggs placed under a hen to hatch are fertile thus early in the season. It is a loss in every way to allow the unfertile eggs to remain under the hen until those that are good have hatched out. Cheap egg-testers can now be had with which anyone can prove whether an egg is fertile or not after it has been under the hen for a few days, and all eggs should be thus tested, only the good ones left to hatch, and the others taken away. After being under the hen for a few days or a week the latter may not be relished at table, but they are very acceptable as food for the young chickens, and do for them as well as the best fresh eggs. Those who may now be setting many dozens of eggs weekly will find it true economy to test and use their unfertile eggs in the manner we have indicated. They should be boiled hard and afterwards chopped fine, shell and all. With many some dozens of unfertile eggs may be found weekly, and there is certainly no better use to which they can be put than giving them as food to the young chicks.—J. MUIR.

[A moderate quantity of chopped egg is very good for the

chicks, but care must be taken not to give too much, as it has a tendency to produce constipation.—ED.]

### THE POULTRY CLUB.

THE first meeting of the Committee of the Poultry Club since the increase of its numbers was held on Thursday, the 24th of February, at the Charing Cross Hotel. There were present the Hon. and Rev. F. G. Dutton, the Rev. H. C. Fellowes, and Messrs. H. R. Dugmore, L. C. C. R. Norris, T. P. Lyon, R. A. Boissier, S. Lucas, J. C. Fraser, and A. Comyns.

The voting papers relating to the recent election were examined, and it appeared that the following were the votes recorded for each candidate:—*President*, Hon. and Rev. F. G. Dutton, 45. *Treasurer*, H. R. Dugmore, 36. *Hon. Secretary*, A. Comyns, 42. *Committee*, T. W. Anns, 35; O. E. Cresswell, 25; Rev. H. C. Fellowes, 41; J. C. Fraser, 36; T. P. Lyon, 37; R. E. Horsfall, 38; L. C. C. R. Norris, 41; Rev. J. D. Peake, 38; E. Pritchard, 41; Rev. W. Serjeantson, 38; Butler Smith, 40; R. B. Wood, 12. Many voting papers had been returned signed in blank, with a request that Mr. Cresswell would fill in the names as he chose. This he naturally had declined to do. As Mr. Butler Smith had been nominated without his own consent his election was declared void, and the Secretary was instructed to issue a notice requesting nominations to the vacant place on the Committee.

The following new members were elected:—C. R. Williams, Waterloo Park, Waterloo, Liverpool; A. Gervaise Bright, English Street, Armagh; Anthony Taylor, Netherbury, near Bedminster, Dorset. — Lloyd, of Douglas, Isle of Man, was elected an associate member.

Directions were given to the Treasurers to pay the subscriptions promised by the Club to the Wolverhampton and Liverpool Shows.

Some complaints by members as to the non-payment of prize money, &c., at various shows were then dealt with, and acknowledgments by members of some similar matters having been settled upon the intervention of the Secretary were read.

A letter from Mr. O. E. Cresswell, stating that the accounts for 1880 had not yet been finally settled, but that he believed there would be a balance, as on the 31st of December last, of £153 8s. 10d. was next read.

The times and places for the meetings of the Committee were next discussed, and it was decided that as far as practicable such of the meetings of the Committee as are to be held in London shall be held at 2 P.M. on each of the following days:—March 28th, April 27th, May 30th, June 27th, July 27th, August 29th, and September 26th. That the meeting in October be held on the Monday in the Dairy Show week. That in November two meetings be held—one at the Crystal Palace, on the Monday in the Show week; and another at Birmingham, also on the Monday in the Show week; and that a meeting be held at Wolverhampton on some convenient day during the Show.

The Secretary was empowered to convene extraordinary meetings in case of urgent business.

The circular to fanciers whose names appear in the "Fanciers' Directory" for 1880, directed by the general meeting to be sent out, was then considered, and a draft thereof approved by the Committee. Directions were given to the Secretary to issue the circulars as soon as possible.

The form of the circular to the Secretaries of shows, requesting information as to the dates on which it was intended to hold the several shows in the ensuing season, was then approved, and directions given for its issue.

The circular to railway companies, as to the rough handling of birds and other similar matters, was discussed; but it was decided that this should stand over until the next meeting, that further information as to certain points might be obtained.

The Secretary was requested, if he should in his discretion see fit to do so, to take steps for bringing the question of the carriage of poultry under the notice of the Parliamentary Committee about to be appointed to inquire into the carriage of stock and agricultural produce.

The Secretary was directed to take steps for obtaining payment of such of the subscriptions for 1880 as had not yet been paid, with a view to the closing of the accounts for that year.

The question of the preparation of a standard of excellence was then shortly discussed, but was postponed until the next meeting of the Committee.

The Secretary was directed to communicate to Mr. O. E. Cresswell the following resolution of the Committee:—The Committee desire to express through their Secretary their grateful sense of the invaluable services rendered by Mr. Cresswell to the Club, both in its formation and during its subsequent career to the present time.—ALEX. COMYNS, *Hon. Sec. Poultry Club, 47, Chancery Lane, London, W.C.*

### SULPHUR VERSUS FEATHER-EATING.

IN reply to your correspondent John Melville, who wishes to know the quantity of flowers of sulphur to use for the purpose of curing the feather-eating propensities in fowls, I have much pleasure in stating that I have been in the habit of giving three tablespoonfuls to twenty-four fowls daily, mixed up with their

morning soft food. He might try two tablespoonfuls at first for his thirteen birds, given once a day. If he finds it scours them reduce the quantity, or give it every second day. If the disease is bad amongst them or of long standing it may take a considerable time before it is subdued. The sulphur appears to supply something which they require and cannot obtain when in confinement. Overfeeding will also, I think, produce it, as that brings on a vicious appetite and diseased habit of body. Doubtless plenty of green food combined with grubs and insects, which fowls obtain when on a grass run, is the best natural preventive; but where we are compelled to keep fowls in a small space, and are not very careful as regards their diet, they will make fat internally, and that tends to induce the cannibal propensities. The sulphur, perhaps, purifies and cools their blood, and so brings them into a better state of health.—F. C. TAYLOR.

### OUR LETTER BOX.

**Fowl Ailing** (*C. M. C., Stroud*).—We fear from the account you give of her symptoms, that your hen is suffering from liver disease. Your treatment has been correct enough so far. Try the effect of a grain of calomel every other day. The lameness is, however, a bad sign, and we fear the hen will not recover.

**Frostbite** (*Idem*).—You can do nothing now for the frostbitten comb. Should such a thing occur again rub the comb well with snow or cold water, and keep the bird in a moderately cold place until the healthy colour returns.

**Chickens with Gapes** (*R. H. A.*).—The only method of curing gapes which we have found thoroughly effectual is the removal of the small worms, the presence of which in the windpipe of the chick constitutes the disease. This can be done by means of a small quill feather from which the greater part of the feather has been removed, only about half an inch at the end being left on. This must be inserted in the windpipe of the chick, the opening of which will be seen just behind the tongue, gently pushed down as far as it will easily go, twisted round, and drawn out again. It will generally be found that there are a number of small worms adhering to the feather. Care must be taken that the chick is not choked during the operation. A difficulty is sometimes experienced by beginners in getting the feather down the windpipe, but by holding the chick's beak open with the finger and thumb of the left hand applied from behind, and pressing the throat of the chick slightly with one of the other fingers of the same hand, the opening of the windpipe can be clearly seen. If the feather be moistened with spirits of turpentine before use it will be an advantage. The turpentine kills the worms, but the feather must only be moistened, not soaked, with it, as a drop going into the lungs would be fatal to the chick. Another mode of cure recommended is holding the chick until nearly, but not quite, suffocated in the fumes of sulphur or carbolic acid. We have not found this cure at all reliable. Scrupulous cleanliness with a liberal use of disinfectants (such as carbolic powder), and the separation of the infected chicks from the others, are the only means of prevention. The ground is said to become tainted with the germs of this disease, so it is as well where possible to avoid putting other chicks where those with gapes have been.

**Bones for Poultry** (*J. S., Cairnie*).—Except for the purpose of allowing them to pick off any scraps of meat, &c., which may be on them, bones can only with advantage be given to poultry after having been crushed in a bone mill, or broken quite small by hand. Bonemeal is largely used to aid the growth of exhibition poultry, and can be purchased from the various dealers in it. It is distinct from bone dust, which is made from the refuse of workers in bone and is useless for poultry.

**Mustard and Cress on Farms** (*Victor*).—The quantity of seed required per acre is for the former about 16 lbs., and the latter about 12 lbs.; both should be drilled at about 14 inches apart in order that the land may be hoed if requisite. The produce of these in seed is so various and so much depending upon soil, situation, &c., and the crop being so uncertain and speculative, as well as in some cases seriously injured by small birds before it can be harvested, that we may only mislead some people if we were to name the quantity of seed which is sometimes obtained.

### REMARKS.

20th.—Rain in morning, dull throughout; sharp showers of small hail from 6.20 P.M., turning to snow at midnight.

21st.—Ground covered with snow 2 inches deep; fair, dull, and cold.

22nd.—Foggy dark morning; cold damp day.

[2.30 P.M.]

23rd.—Fair first part of morning; slight snow at noon, falling thickly from 24th.—Fair throughout; clear sky and bright sunshine for short time in middle of day.

25th.—Fair, but overcast, damp, and cold; bright starlight evening.

26th.—Fine with bright sunshine in middle of day, but overcast at night.

Temperature equable and low, with a heavy fall of snow on 21st, and another of rapidly melting snow on 23rd.—G. J. SYMONS.

14th	M	Royal Geographical Society at 8.30 P.M.
15th	TU	
16th	W	Society of Arts at 8 P.M.

### DAHLIAS AND THEIR CULTIVATION.

THESE popular flowers are no longer restricted to the Show and Fancy varieties, but there are now so many different forms that growers may make selections for their several different purposes. The large Show varieties still hold their own for exhibition as heretofore, and when well grown are amongst the noblest of autumn flowers, lasting well in a cut state, but far too formal to be used as decorative flowers. To supply this want there is now a very large number of Bouquet or Pompon Dahlias, the various single varieties, and the latest introduction, the Cactus Dahlia (*D. Juarezii*), all of which during the autumn months have few equals. Cut as sprays with buds and leaves, and associated with other flowers, they are admirably suited for large vases. Gardeners as a rule have two important seasons with most plants—the seed time and harvest, or in other words, while plants are flowering is the time to make notes on their good or bad qualities, and mark selections for raising or increasing the plants when the proper time arrives. Dahlias, since the foliage was blackened in November by frost and the roots stored in their winter quarters, have been almost dormant, and now the period of the year has arrived to work upon the observations made when the plants were in bloom, and with this object these notes are contributed.

**PROPAGATION.**—The most common methods for increasing a stock is by dividing the roots and by cuttings; by this means the same varieties are perpetuated. New varieties and many of the single kinds are raised from seed, and in some few cases grafting is practised.

**Division of the Roots.**—This consists of dividing the root from the crowns or stems downwards, taking care to have one or more eyes to each division. Pot each piece or division in light sandy soil, and place them in a shady temperature, where they will break and make strong plants by planting-out time. This is a very old and simple plan, and if only a small quantity of each variety is needed is very safe.

**Cuttings.**—For all ordinary purposes the first or second week in March is the most suitable time to place the tubers in a warm situation to start. If the collection be small they may be placed closely together in boxes, seed pans, or large pots, covering the roots with light leafy soil or cocoa-nut fibre refuse, placing them in a temperature of 65°; but for larger collections a gentle hotbed or the side stages of a stove or vinery may be employed. The young shoots usually appear soon; three, four, or more rising up from near the stem of the old plant. These when about 2 inches in length may be taken

off with a sharp knife close to the old tuber, inserting each cutting singly in small pots filled with leaf soil and silver sand. Plunge these pots in a strong bottom heat in the propagating house or hotbed, keeping the soil moist until the cuttings are rooted, which will usually take from two to three weeks. When rooted gradually harden them, and give them a shift into larger pots and richer soil. When well established in the latter pots remove them to a cold frame until the weather is favourable for planting them out in their summer quarters. Cuttings treated in this way are usually sturdy by planting time, and afterwards the plants grow rapidly and flower very freely during the early autumn.

**Seeds.**—Since the single varieties are growing more in favour with the public this method of raising a collection has much to recommend it. Sow very thinly in shallow seed pans, placing them in a hotbed with a temperature from 60° to 70°. In that the seed will soon germinate, and the plants will require timely potting-off and hardening similar to that recommended above for cuttings. We know an amateur who has for many years thus treated the Dahlia as an annual, and he has been very successful. Some of his varieties have, indeed, been almost suitable for exhibition. When the plants are grown solely for home decoration and no convenience exists for storing the roots, the plan alluded to is worthy of a trial.

**OUTDOOR CULTIVATION.**—All Dahlias are very strong-rooting, and to obtain plenty of flowers the plants must be well supplied with stimulants. A very good practice is to mark out the places allotted to them. Four feet apart is a fair distance, placing a strong stick at each spot, and removing the ordinary soil in front of it, replacing with a richer compost of loam and manure. Tie them loosely to the stakes at once, or the wind will snap the young heavy growths. The end of May or early in June is about the most favourable time for planting, but when planted in masses much taste accompanied with a knowledge of the varieties with regard to colour and height are needed to keep the tallest either at the back or centre of the mass or bed. In some catalogues their relative heights and descriptions can be obtained; but we may here observe that most of the Show varieties are the strongest-growing plants, usually from 4 to 5 feet in height. Many of the single varieties are tall, while the Bouquet varieties or Pompons are more slender and dwarf. The bedding varieties are usually the shortest, so that in planting the bedding and Bouquet varieties should always form the two outer rows. When the plants have started into strong growth cover the surface of the soil around each plant with a mulch of stable manure. This will protect the roots during drought. In Dahlia-growing tying is a most important operation; it is imperative that the plants be timely secured, and a constant watch afterwards kept that the ligatures do not become too tight for the rapidly increasing growths.

**INSECTS.**—Growers of these flowers have several pests to contend against. Slugs are very destructive to young plants; a dusting of lime over the plants when moist with dew, or a little placed around the stem, is a good preventive of their attacks. Earwigs and thrips are both troublesome and destructive to the flowers, specially during dry hot summers. Earwigs are trapped by placing small inverted pots partially filled with hay or moss on the stakes, or the stalks of Broad Beans cut from 6 to 10 inches in length, and placed in various positions

about the plants. The insects will, after feeding on the flowers during the night, take shelter in the hollow stem of the bean-stalk, and can be placed in a pail of hot water in the morning. Well syringing the plants and flowers twice a day is the only method of stopping the increase of the troublesome little insect—thrips.

**LIFTING.**—It is most probable that by the middle or end of November the flowerstalks will be completely dead. When this takes place the stems should be cut off to within 8 or 10 inches from the ground, and on the first period of dry mild weather carefully lift all the roots, placing to each its respective name, and pack them in a dry place free from frost until the time arrives around for starting them into growth to obtain a new stock. The following are all good varieties :—

**Show Varieties.**—Admiration, Acme of Perfection, Artiste, Benjamin Crossland, Christopher Ridley, Constancy, Countess of Lonsdale, Cremorne, Criterion, Henry Bond, Flag of Truce, James Cocker, James Service, John McPherson, John W. Lord, John Wyatt, Louise Neate, Leah, Ovid, Prince Arthur, Royalty, Sarah McMullen, Toison d'Or, and Victory.

**Fancy Varieties.**—Barnaby Rudge, Gaiety, Chang, Charles Wyatt, Ebor, Enchantress, Flora Wyatt, George Barnes, Hereules, Henry Glasscock, Letty Coles, Mrs. C. Smith, Mrs. Saunders, Mons. Chauvière, Peacock, Rev. J. B. M. Camm, Regularity, and Singularity.

**Bedding Varieties.**—Rising Sun, Dr. Webb, Sir James Watts, Drap d'Or, Marguerite Bruant, and Mont Blanc.

**Liliputian, Pompon, or Bouquet Dahlias.**—These are remarkably distinct and pretty, many of the flowers produced are not over 1 inch or  $1\frac{1}{2}$  inch in diameter. All the following are worth cultivating—Burning Coal, Dr. Schwebes, Crimson Beauty, German Favourite, North Light, Fireball, Prince of Liliputians, Little Dear, Little Wonder, Louis Rodani, Lady Blanche, and White Aster.

The single varieties are not very numerous. The following comprise the best—Paragon, Cervantesii, aurantiaca, lutea, coccinea, glabrata, and alba.—**FLORIST.**

#### ECONOMICAL METHOD OF SOWING PEAS.

MY remarks on "Early Peas" (page 85) furnished a text for some practical and instructive remarks by Mr. Harding (page 126), especially with regard to protecting Peas from birds. In spite, however, of Mr. Harding's affirmation to the contrary, I still assert that late autumn sowing is often a waste of labour and seed, especially on cold heavy soils or where sparrows are very numerous and voracious. Had I substituted "invariably" for "often" I should have been easily proved in the wrong, as I well know that by close attention good results have followed autumn sowing, on light sandy soils especially. Mr. Harding admits early Peas will not succeed if sown on heavy land, and how many gardens are there where comparatively heavy land prevails! Such was the case at Orsett, and it is the same here. Mr. Harding by good culture preserves his Peas during the winter from frosts and birds, but in the course of a few days "outing" I noticed several rows of autumn-sown Peas completely cut down by frosts, and that too in a favoured part of Kent. Mr. Harding would submit they were sown too early, or were improperly earthed up. No doubt by sowing very late in November but little growth will be made during a severe winter; but what if the early winter be mild, followed say towards the end of January by severe frosts? Many soils, again, if interfered with towards the end of November would be found in very poor condition for seed-sowing. I find the root-action of any crop of Peas very defective should the ground be excessively cold and wet when they are in a young state, and many varieties do not thoroughly recover from the check they thus receive.

With regard to Mr. Harding's selection of Peas, I must express surprise that he has not given some of the "latest new and expensive varieties" a trial, as he would certainly be rewarded by the discovery of several varieties much superior to those older favourites he has named. For instance, Huntingdonian I am convinced is really an improvement on Champion of England: and such old varieties as Auvergne and Laxton's Supreme are far surpassed by Dr. McLean, Marvel, Carters' Challenger, and others—not, perhaps, as far as productiveness is concerned, but more with regard to superior quality. Of the older varieties Veitch's Perfection and Yorkshire Hero are undoubtedly excellent in every respect; but what is the difference, if any, between the two? I

have seen both growing by the acre as well as in private gardens, but I must confess to an inability to separate them.

Although I have taken this opportunity of replying to Mr. Harding's very acceptable comments, the above heading was chosen more with regard to sowing for later crops, and relates to a practice which for aught I know to the contrary is original. I am a believer in tall-growing Peas for one important reason—they are less injuriously affected by either a dry, or wet season than are those of medium growth. Unfortunately many of the best of the tall growers, including Huntingdonian, do not produce pods on much of the lower part of the haulm, and to obviate this waste of stakes and space between the necessarily widely sown rows I decided to try the plan of sowing a medium-height variety in the same rows. The result was most satisfactory in each instance, and I strongly recommend the practice to those with limited space, or who are obliged to economise their stakes. It is particularly suited to those who are in the habit of disposing their rows of Peas at wide distances apart, and filling the intervening spaces with three or more rows of Broccoli or Brussels Sprouts.

The most profitable mixture I have yet tried consisted of Huntingdonian in the centre, and a line on each side about 6 inches clear, sowed with a mixture of Little Wonder and Dr. McLean. The seed was sown thinly, the outside lines earthed up; stakes were put according to the height of the central variety, and a row of Peas resulted that was covered with pods almost from the ground upwards. Huntingdonian was the first to be picked from, this being closely followed by the other two, and which, although unlike in appearance of pods, are still well adapted for cooking together. Probably no three better quality Peas are grown. On the whole I prefer sowing two varieties together—such for instance, as Telephone, with outer lines of Stratagem, Fortyfold, and Princess Royal; Ne Plus Ultra and Omega; Royal Berkshire Marrow and Hair's Dwarf Mammoth, the latter not so often grown for late crops as it deserves to be; Williams' Emperor of the Marrow and Premier, and in fact any tall and medium height varieties.

I do not recommend the practice where the soil is poor and manure scarce, as one variety undoubtedly much impoverishes the other, neither should the seed be sown thickly or the rows be crowded. The rows ought at least to be as far apart as the average height of the central tall variety. Last season especially the tall-growing Peas attained to extraordinary heights, the lower parts of the rows yielding but few pods; but where a medium height variety was sown with them the exuberant growth was checked considerably, and the results compared most favourably with those grown on the old system. No extra labour is necessitated other than drawing three narrow drills instead of one wide one.—**W. IGGULDEN.**

#### A TRIO OF USEFUL PLANTS.

**Euphorbia jacquiniæflora.**—Few gardens where a stove temperature is available should be without this lovely plant. Either in pots or planted out as a climber it seldom fails to give abundance of its brilliant flowers. It also endures cutting for decorative purposes well, the flowers being much appreciated for ladies' hair.

**Staphylea colchica.**—Among plants for forcing this cannot be too highly recommended. It is easily forced, and plants in small pots produce a dozen spikes of fragrant flowers each. The plant may be removed to the conservatory or to the drawing-room, and will keep in good condition for three weeks at least.

**Begonia metallica.**—One of the best of the numerous fine-foliage Begonias. It is easily propagated, makes a good plant quickly, and is admirably suited for decoration, either to form in a group or as a single plant, also for the dinner table. In summer I have known it grow quite 6 inches in the drawing-room, and keep its colour and vigour for two months.—**A.**

#### GLASS STRUCTURES FOR AMATEURS.

(Continued from page 550, last vol.)

**HEATING.**—Great complexity exists in the forms of boilers for heating horticultural structures, but this is often due to the number of parts directly or indirectly exposed to the action of the fire. Those which present the greatest surface and the greatest obstruction to the passage of the fire over its surfaces immediately at the point of greatest heat, are best calculated to abstract the greatest amount of heat from the fuel. Those parts must be at the sides, over, and end of the furnace, for surfaces not acted on directly are of very little value. It is also worthy of note that the greater the surface exposed in proportion to the quantity of water contained in the boiler, the greater will be its

heating capacity. A foot of surface will heat to a given degree a pint of water in less time than it would a quart; thus, a boiler with 3 feet of surface will heat as much water to say 200° as one with 6 feet, the quantity being half in the first case as regards the boiler to what it is in the latter. It is the increase of surface and the diminution of water space that gives to tubular boilers their superiority over those with large waterways—a quantity of water to be heated before any of it passes to where it is required, and a decreased heating surface; the circulation is rapid with the one, in the other slow. Unfortunately the most improved forms of boiler are not made in small sizes suitable for the amateur, and in selecting a boiler it is always advisable to have one capable of heating considerably more piping than it is calculated to do. The saddle form of boiler is still one of the best for small houses, especially those forms that have waterway terminal end and side flues.

In regard to pipes, those 4 inches in diameter are the best, as they retain the heat longer than the smaller do. The flow pipe should ascend from the boiler to the point of return, and the return pipe should descend thence to the boiler, so that an air pipe at the highest part of the pipes will keep them free of air. Avoid dips, they only impede the circulation and diminish boiler power. The joints after caulking with tarred rope may be filled up with cement. In fixing the supply cistern have it on such a level that the flow pipe will not be more than three parts full of water where it makes the return, this to allow for the expansion of the water and prevent running over at the air pipe. The supply of water to the feed cistern should be regulated by a ballcock, and the supply from it be either to the boiler direct near its bottom, or to the return pipe as near the boiler as practicable, and at its passage from the supply cistern there should be a valve to check the water from running back into the supply cistern. The pipes may be on a level in the house or one above the other, and if they have a rise of half an inch in a yard within the house it is ample. To regulate the draught of the furnace there must be either a door to the ashpit so that the draught may be regulated, or a damper in the boiler flue, or both.—G. ABBEY.

#### TEA ROSES.

At the late meeting of the General Committee of the National Rose Society, when the Crystal Palace schedule was under consideration, a member drew the attention of the Committee to the nurseryman classes for Tea Roses. In class A prizes were offered for eighteen, and in class B for twelve. It was pointed out by the Secretary that these numbers must be altered, because the giver of the prizes (Mr. Prince of Oxford) had offered them for twenty-four and eighteen respectively. Twenty-four Teas and Noisettes! The number struck me as exceedingly large, and as Chairman I ventured to suggest that, though it was not a proper thing to look a gift horse in the mouth, yet that surely these numbers were too large; for what member of the Committee could name twenty-four good Teas and Noisettes? A great authority on Teas (Mr. Cant of Colchester) supported me by saying what I scarcely ventured to hint, although I was thinking the same thing—that it was often exceedingly difficult to get twelve good Teas in a box, and it would be almost impossible to have twenty-four. It was felt, however, that we had no alternative but to make the alteration desired by the donor, and so it now stands. But my object in writing this is to ask your rosarian readers if any of them can name twenty-four good Teas and Noisettes, nearly half of which would not have been out of bloom by July 2nd, the date of the Crystal Palace Show?

Several years ago I showed Roses, but some of my friends may remember that Teas used to be my strong point, and I believe I may claim without boasting to be one of the first to discover the beauties of Catherine Mermet, when neither Mr. William Paul or Mr. Robert Baker had it in their collections; and when devoting a large part of my attention to Teas and growing all the varieties then in commerce, after having built dwarf walls on purpose to protect the plants, I have generally had the greatest difficulty in producing twelve good Teas and Noisettes for a box. Catherine Mermet, Alba Rosea or Madame Bravy, Maréchal Niel, Souvenir d'un Ami, Elise Vardon, Devoniensis, Triomphe de Rennes, La Belle Lyonnaise, and sometimes Madame Trifle—all these are good, but how about the rest? There are plenty of Teas left, you say. Yes, but let us look at them. You go round to Niphetos. Here she is, with drooping head, snow white in colour, and looking from a distance lovely; but lift the bloom up, and you will ten to one find her all out of form. Then there is Madame Margottin; in nine cases out of ten she is quartered or of bad form. I can only recollect one really grand Madame Margottin at a show, and that was exhibited by my friend Mr. Baker at Torquay, and I

believe wrenched the first prize. Then there is Souvenir de Paul Neyron, which is generally too small for a box, and a number of lovely yellow and sulphur varieties, which are such poor growers—like Reine du Portugal, Louise Savoie, and others—that very seldom can a good bloom be obtained from them out of doors.

There have been numbers of good new varieties, so I am told, but I have only seen one—Madame Lamhard—which really attains to first-class honours. But now we are flooded with this new race, this *belli teterrima causa*, "Hybrid Teas." Are Mr. Bennett's hybrids and Mr. George Paul's Cheshunt hybrids to be admitted into Tea boxes? Cheshunt Hybrid has always found a place therein, but most judges have shrugged their shoulders as they found it amid those dainty beauties, and wished in vain that they could turn it out or disqualify the box. But now we are threatened with a flood of Hybrid Teas, which, so far as I can understand, bear the same relation to Teas as La France does. If these, then, are to be admitted into an exhibition stand of Roses we can understand the numbers fixed upon by Mr. Prince, although most rosarians will, I think, agree with me in deeming that one of the most lovely sights of a Rose show—the box of Teas and Noisettes—will be entirely ruined. Is it too late to alter this? If not, I would beg the donor of these prizes to consider the matter and report his decision to the Committee.—WYLD SAVAGE.

#### A SELECTION OF POTATOES FOR 1881.

HAVING just made up my list of Potatoes for the coming season I send you an abstract of it. All the sorts named are good, but they vary much in their distinguishing features; therefore I have attached letters to indicate their strong points. These letters afford a justification (good or bad as the case may be) for the selection at every point, and will, I hope, be useful to cultivators who are not posted up in minute details. *x* Signifies particularly well adapted for exhibition; *t* signifies high table quality; *c* signifies that the variety is what we term a "heavy cropper;" *m* signifies peculiar adaptability for market culture, combining heavy cropping with a strong constitution.

Ashleaf, *t*; Avalanche, *t x*; Beauty of Hebron, *x*; Beauty of Kent, *t x*; Bedford Prolific, *t x*; Blanchard, *x*; Bountiful, *t x*; Bresce's Prolific, *x m*; Brownell's Beauty, *x c*; Centennial, *x*; Climax, *t x*; Covent Garden Perfection, *t c*; Crimson Ashleaf, *x*; Dalmahoy, *t c*; Early Market, *t m*; Edgcott Seedling, *t x*; Excelsior Kidney, *t x*; Fortyfold, *t m*; Garibaldi, *x*; Grampian, *t x*; Heather Bell, *t x c*; Ice Cream, *t x c*; International Kidney, *x*; Johnston's Downshire, *t c*; Improved Peachblow, *x*; King of Potatoes, *t x c*; Lapstone, *t x*; Magnum Bonum, *t m*; Manhattan, *x c*; Matchless, *t x*; Model, *x*; Mr. Bresee (syn. Peerless Rose), *t x*; Porter's Excelsior, *x*; Radstock Beauty, *x c*; Rector of Woodstock, *x*; Red Emperor, *x*; Salmon Kidney, *x*; Schoolmaster, *t x c*; Scotch Blue, *x*; Scotch Champion, *m*; Snowflake, *x m*; Striped Don, *t x*; Triumph, *t x c*; Vicar of Laleham, *x c*; Wiltshire Snowflake, *t x*; Woodstock Kidney, *t x*.

A selection from the foregoing should comprise Myatt's Ashleaf, Beauty of Kent, Bedford Prolific, Covent Garden Perfection, Early Market, Edgcott Seedling, Fortyfold, Grampian, Hooper's Round White, Johnston's Downshire, King of Potatoes, Magnum Bonum, Rector of Woodstock, Schoolmaster, and Triumph. These fifteen will make for anyone a really fine collection.—SHIRLEY HIBBERD.

#### FLORIFEROUS HYACINTHS.

I SHALL be glad to know whether any attention has been called to the remarkably floriferous character of the Hyacinths this season, as after many years' experience neither my gardener nor I have seen them so fine. The bulbs have been sent direct from the same Dutch grower for the last twelve years, and I always have the same old favourites, as, only seeing them once a year, there is no time to tire of their beauty; whilst I have found that with novelties it is price that constitutes the great difference in the majority of cases. I have generally had a fine display, many of the spikes being really fit for exhibition, but this year they are extraordinary, with two, three, four, and in one case six spikes. I give a list of some of the most remarkable specimens; and at the same time I would observe that although some of the spikes may be said to belong to offsets, in many cases they spring from the centre of the bulb, and apparently from the very heart.

Why do the bulbs never furnish such fine spikes of bloom the second season, no matter how carefully they have been grown in the interval? Of course the young offsets can only produce weak spikes, and must improve with age. Is it the practice to prevent them flowering until they are considered marketable bulbs, or are they allowed to flower annually until they have attained such distinction? A few hints might be acceptable to

some readers, as I remember reading many years ago, in one of the numbers of the *Cottage Gardener*, an article from the pen of the late Mr. Donald Beaton, complaining of the fact that gardeners were in the habit of throwing away the offsets of their Tuberoses, under the impression that they could only be grown under the sunny skies of Italy. I fancy it was before we found that American Tuberoses even surpass the Italian.

*List of Multiple-flowering Hyacinths.*—L'Ornement de la Nature, four central spikes, three of them large; Garrick, one very large central spike, and one good offset; Argus, two large central spikes, and one good offset; Frederick the Great, three large central spikes, and one small side spike; Grande Vedette, one very large and two small central spikes, also two small side spikes; Lord Wellington, one grand central spike, and one smaller central spike; Victoria Alexandrina, one large and five small, all central spikes.—C. M. MAJOR.

#### THE GOOSEBERRY CATERPILLAR.

I WISH to know something definite about the Gooseberry caterpillar. I am always being told that it is reared from the egg of a moth, but I find by putting tan round Gooseberry bushes that the caterpillars are kept at bay, so that the young or eggs must be in the ground below the bush. But supposing there are caterpillars on the bushes, will they breed themselves? I will not assert that the first lot is not produced from the butterfly, but I have had proof that afterwards they produce themselves. Tan has no effect on wall trees, so the caterpillars must be in the wall. An explanation of this will much oblige.—COMBER.

["COMBER'S" letter was submitted to an entomologist, and the following is his reply:—

"The principal Gooseberry caterpillar is that of the moth named *Abraxas grossulariata*, the economy of which may be thus briefly described. The eggs, which produce the only annual brood of caterpillars, are deposited by the parent moths during June or July, the time varying with the season, but they are usually on the wing for several weeks. Occasionally the eggs are discovered in patches. The moth in the usual way, however, only places one egg on a leaf, hence not much can be done towards checking its increase by the removal of eggs. Emerging in August, or earlier, the caterpillars feed for some time, but grow slowly in some seasons. On the approach of autumn they prepare for a winter sleep. Some rest on the bushes almost unprotected; some draw together a withered leaf with a few threads, ensconced in which they descend to the ground; and some lay up in odd corners, such as nooks on palings, empty flower pots, and so on; hence there is no doubt that tan placed round the bushes might do something to prevent the return of wanderers in the spring, and also kill any that may be upon the earth. With this insect, as with others, it now and then happens that what we suppose is due to some precaution on our part arises from a natural cause, which has stopped the development of an insect enemy. As a rule these caterpillars thrive better in a dry cold winter than in a moist one; some die, and some are eaten. The remainder reappear about the end of April or May, when many persons suppose that they have just hatched, not connecting them with the caterpillars that were seen upon the bushes in the autumn. When full fed the caterpillar turns to a chrysalis upon the food plant, forming a very slight cocoon, within which the yellow and black chrysalis is very conspicuous, and should be removed wherever seen. It is not in the power of these caterpillars to produce either eggs or young caterpillars, therefore anything alive that may be detected in the interior of one of them is the larva of a parasite, usually that of some tiny fly. Though commonly associated with the Gooseberry, the caterpillar of *A. grossulariata* feeds also upon the Currant, preferring the black variety. The caterpillar of a lesser species of moth, *Halia Wavaria*, occurs on the Gooseberry. This is at once distinguishable by the black warts which stud the pale green body. Every gardener has seen another species doing mischief—the pseudo-caterpillar of the Sawfly, *Nematus Ribesii*, which infests Gooseberries, feeding in companies with tails raised in the air, and upon which some interesting observations appear in the volume for 1880, page 431."]

#### MARÉCHAL NIEL ROSE ON ITS OWN ROOTS.

I WISH to say a few words in support of Mr. Bardney's remarks (page 146) regarding Maréchal Niel Roses on their own roots. Last year we purchased from a nurseryman two Maréchals in pots which had been worked the same year on the Manetti or Briar—I cannot positively say which—for planting in a warm greenhouse. When they came to hand I turned them out of their pots to see in what condition the plants were, and found they had made a

number of roots, but were all then apparently dead, at least all the young fibrous roots. The plants had most likely been grown in a rather high temperature, probably plunged in bottom heat to force a certain amount of growth, and afterwards placed in a much lower temperature, and in consequence they would be severely checked. After seeing the state the roots were in I deemed it advisable to defer planting that season and to grow them in pots until the following year. I therefore waited until they started, then reduced the soil a little from the roots, and repotted them in the same size pots. One of the plants grew as well as could be expected, the other kept alive and that was all. As before stated, I intended planting them out this year, which I did about a month since. Last week I noticed the large plant drooping its leaves, while the small one that had scarcely made any growth the previous year was doing well. How to account for it I did not know, so I determined to lift and carefully examine both, when to my surprise the small plant was rooting well and the large plant that had grown so freely the previous year had not a live root. The stock proved to be dead, also the stock of the other, but having been worked lower it had emitted roots from the union to support itself. I know several plants of the Maréchal doing well on their own roots, and have grown them successfully so, but not otherwise.—J. RICHARDSON, *Calverton Hall, Notts.*

ON page 147 I referred to the Maréchal Niel Rose under the charge of Mr. Hanagan, Hooton Hall, and wish to correct the statement in relation to the number of blooms cut from his tree last year. I wrote entirely from memory, and find from a letter now before me that three thousand blooms were cut instead of four hundred, as stated. An account of the number of blooms produced by the tree was not kept previous to 1880, but in that year it was estimated that fully one thousand more expanded than in 1879. The tree in question was planted in August, 1874, and was then about twelve months old, though very small. It had not been pushed forward in its early stages, as it was thought it would not be required for planting that season. However, two large plants on the Briar died, and the small one upon its own roots was then planted out. It continued growing until late in the season, and the following spring a strong shoot was noticed coming from the bottom; this was allowed to grow a few feet in length, when the whole of the previous-made wood was cut away. The shoot grew rapidly and strongly until it reached the top of the greenhouse wall, 10 feet in height, which is the length of the clean stem alluded to. The point was then taken out, and the plant allowed to branch to cover the roof. A few good blooms were cut from the plant in 1876; the number yearly increased, and Mr. Hanagan says seven thousand blooms is under the total number cut from this fine tree. There is, he informs me, every prospect of it producing three thousand again this year. Two shoots are now observed starting from the clean stem half way up; and Mr. Hanagan thinks, after blooming is over and these shoots are a few feet in length, of cutting the whole of the old wood away, and allowing these shoots again to occupy the roof. He contends this adds fresh life and vigour to the plants, as he has done the same with other plants of this fine Rose under his charge from time to time, and always with success. This I consider is a wise course to pursue. What says "OXONIAN?" The strain of producing thousands of blooms annually must in time exhaust the vigour and energies of any Maréchal Niel, or any other variety of Rose. By cutting it back growth will be vigorous and the production of flowers smaller for a year or two, thus allowing the tree to recruit itself to again produce in due time thousands of blooms. With judicious care in this respect, which Mr. Hanagan knows well how to exercise, the tree in question may be kept in good health for many years.

If young plants of Maréchal Niel, say twelve months old, were allowed to carry all the blooms they would produce, it must considerably arrest their vigour and impede growth the following year; therefore the majority of the blooms should be picked off and the strength of the plant devoted to the production of wood until thoroughly established. The vigorous habit of young plants on their own roots and their freedom to bloom is, I fear, too frequently the cause of insignificant growth the following year. Then the Maréchal is condemned as unsatisfactory, and will not do on its own roots, while the fault is entirely due to the cultivator, who is desirous of having all the blooms the plant will produce, and in consequence exhausts its energies and cripples the plant in its early stages. It is a well-known fact in growing specimen plants, say of Heaths, that if allowed to bloom from their earliest stages a much longer time would be required to produce a specimen than if the flowers were picked off or never allowed to form. What cripples young Vines or Peach trees sooner than heavy cropping

at once after planting? The same facts apply with equal force in my estimation to the young Maréchal Niel Rose. Mr. Hanagan has this Rose doing well on the Briar, and no signs yet of going off; but he says, "I prefer them on their own roots, as I have lost two large plants on the Briar by canker."—WM. BARDNEY.

### ANGRÆCUMS.

(Continued from page 154.)

THREE of the best species have already been described; but as there are several other forms of scarcely less beauty or interest, a few additional notes are requisite to indicate the chief characters of the genus. Some of the most recently introduced species, though possessing attractions of no mean order, are, unfortunately, still comparatively rare in cultivation, this being due either to the difficulty of propagating them, or to the circumstance that very few importations are received. However, the majority of those mentioned in the following notes are in the collections of the chief nurserymen and amateur Orchid growers.

*Angræcum Kotschyi*.—Another of the beautiful species which Messrs. Veitch & Sons have brought into notice, and for which they obtained the coveted award of a first-class certificate at the meeting of the Royal Horticultural Society, October 12th, 1880. It not only possesses sufficient attractions to render it a worthy companion for the best of its genus, but the peculiarity of its structure is additionally interesting, and on the occasion named the plant exhibited received much attention. Like its allies it is epiphytal in habit, being found on trees near Zanzibar. The shining green leaves are rather short and broad; the creamy white flowers being 1 to 1½ inch across, and produced in pendulous racemes about a foot long. Each of the flowers is furnished with a reddish-tinted spur 6 or 7 inches in length, but, unlike all other *Angræcums*, it is curiously twisted somewhat in the manner of tendrils. This is the peculiar part of the plant's structure, and has given rise to several opinions as to its probable utility to the plant. The Rev. G. Henslow, when describing the plants exhibited on the occasion named, referred to it, and hinted at the possibility of the spurs not only resembling tendrils in appearance but in function also, and that they may possess a certain sensitive-ness which would enable them to twine round contiguous objects, thus supporting the rather heavy inflorescence. The surmise appears very reasonable, but further observations are required to substantiate it. However, apart from this, *Angræcum Kotschyi* is a charming and graceful Orchid, and I understand that it will be one of the choice novelties Messrs. Veitch intend sending out in the present year, so that growers will have an opportunity of adding it to their collections.

The species is named in honour of Theodor Kotschy, who found it a year or two previous to 1840, and it has been since discovered by several other travellers. The plants that have now been introduced were, I am informed, originally sent by Dr. Kirk to Gerald Waller, Esq., from whom Messrs. Veitch obtained them.

*A. bilobum*.—One of the better known forms, which is included in most of the large trade collections of Orchids, and occasionally seen in gardens where those plants receive more than ordinary attention. It is intermediate in vigour and habit, being less strong in growth than *A. eburneum*, and more robust than *A. Kotschyi* or *A. falcatum*; but it thrives very well in a basket, and may even be grown upon a block, though the former system of culture is generally the more satisfactory. The plant is rather compact, with dark green moderately broad leaves, two-lobed at the apex, and arranged in a distichous manner. The flowers are about 1½ inch in diameter, white with a tinge of rose, each having a spur 2 inches in length; they are borne in long pendulous racemes, and possess a slight fragrance. Specimens were found by Mr. Bowdich when travelling in West Africa near Cape Coast Castle, and from his widow Messrs. Loddiges obtained plants more than forty years ago, thus first introducing it into English and probably to European gardens.

The woodcut does not represent the plant full size, being reduced nearly half, but it well indicates the habit and chief floral characters that mark the species.

*A. Ellisii*.—Comparatively few persons have had an opportunity of seeing this handsome species in flower, for although it has been in commerce some years it is still rather scarce. A few years since, however, there was a very beautiful specimen in Mr. Day's fine collection of Orchids at Tottenham, said to be one of those originally introduced from Madagascar by the Rev. W. Ellis, after whom the species is named. That plant has flowered at least once to my knowledge several years ago, when it was greatly admired by all who were fortunate enough to see it. To Mr. B. S. Williams is due the honour of placing the plant in

commerce; and on April the 6th, 1870, he exhibited it before the Royal Horticultural Society, deservedly obtaining a first-class certificate.

The plant is of rather noble habit, having handsome dark green leaves 9 or 10 inches in length and 2 inches broad, cut at the apex into two unequal lobes, and arranged in the characteristic two-ranked or distichous manner. The flowers are pure white and possess a very pleasing fragrance; they are about 2 inches across, with narrow reflexed sepals and petals; the column standing very prominent, and the pale brownish spurs vary in length from 6 to 8 inches. The spikes are frequently 2 feet long, gracefully arching, and bearing about twenty flowers. Though an

[Fig. 44.—*Angræcum bilobum*.

epiphyte it thrives best in a pot, like the other *Angræcums* of moderately strong growth.

*A. Scottianum*.—One of the diminutive forms of the genus, but none the less pretty on that account for its distinctness from allied species, and the delicacy of the flowers impart considerable interest to the plant; yet it is still somewhat rare, and I have only seen specimens in a few of the largest collections, but that is probably due to the fact that the three or four years it has been in this country has not been long enough to permit very extensive propagation, and I have not heard of any importation during that period. When better known it will no doubt be included in most collections of moderate extent, as it deserves the attention of all growers who do not limit themselves to the merely showy Orchids. It is epiphytal in habit, with narrow terete leaves, very dissimilar from most other *Angræcums*; they are tapering or awl-shaped, about 4 inches long, and one-eighth to a quarter of an inch in diameter, channelled in the upper surface and ridged below. The flowers are of a moderate size, very delicate in texture; the lip an inch or more across, pure white, with a narrow yellowish spur 3 to 4 inches long. The peduncle is slender and usually bears but one flower. The species is a native of the Comoro Islands, and I believe first flowered in this country at Waltham-

stow in 1878 in Mr. R. Scott's collection of Orchids, and in honour of that gentleman it has received its name.

*A. pellucidum*.—A species from Sierra Leone, whence it was obtained by Messrs. Loddiges, and in their nursery it flowered in November, 1842. The plant is of rather bold habit, with large bright green leaves frequently exceeding a foot in length. The flowers are white, of a delicate semi-transparent texture, having a finely fringed labellum, and are produced closely on racemes of moderate length. Like the majority of species it usually flowers during the winter months, and thrives either on a block or in a basket suspended from the roof of a warm house. Though not by any means common it is fairly well known, and is included in most of the large trade collections. A coloured plate of it was published in the "Botanical Register" thirty-seven years ago, or about two years subsequent to its first flowering at Hackney.

*A. pertusum*.—Like the last-mentioned this is a native of Sierra Leone, but I do not know to whom is due the credit of first introducing it to England. It appears, however, to have been in cultivation several years before *A. pellucidum*, as it was sent to Kew about 1850 by Messrs. Jackson of Kingston, but had previously flowered with Messrs. Loddiges, for it was noticed in Paxton's "Magazine of Botany" in 1840. It is a very distinct form, with long narrow dark green leaves, and slightly nodding racemes 6 to 7 inches long of small closely placed creamy white flowers, which in their mode of arrangement are suggestive of *Dendrochilum glumaceum*. The spurs are comparatively short, and with a well-marked yellow tinge, which gives a peculiar appearance to the inflorescence.

*A. Chailluanum*.—Named in honour of M. Du Chaillu, by whom specimens were first sent to Kew from Gaboon. Another traveller in the same district also sent some to Kew, where a plant flowered in May, 1866, and from that an admirable plate was prepared for the "Botanical Magazine." The genus is still rare, and the only London nursery in which I am aware it is grown is that of Messrs. Veitch at Chelsea, where it has flowered several times, but owing to its scarcity it is necessarily expensive. The plant is rather dwarf in habit, but moderately strong compared with some of its delicate allies. The leaves are 6 inches in length,  $1\frac{1}{2}$  inch broad, slightly wavy and two-lobed at the apex, being arranged in an imbricate manner. The flowers have narrow acute white sepals and petals, and a yellow spur 4 inches or more in length, the raceme being sometimes 8 inches long and elegantly drooping. It is a handsome species, and deserves to become more generally known. It may be grown on a block.

*A. distichum*.—This is very interesting owing to the peculiar form and arrangement of the leaves, and the diminutiveness of the plant. It affords a very striking contrast compared with *A. sesquipedale* both in the size of the flowers and general appearance. While the latter has the largest flowers in the genus and order and is of bold habit, *A. distichum* possesses unusually small flowers, certainly among the smallest of the order; and the short stems in tufts, with closely imbricated dark green leaves, still further add to its distinctiveness. In the habit of the plant there is little to suggest affinity with the *Angræcums* to casual observation, but there is a family likeness in the small white spurred flowers, which are produced from the axils of the leaves. However, by some authorities, for instance the younger Reichenbach, I understand that it is considered sufficiently distinct to be assigned to another genus—namely, *Aeranthus*, but the older name is still retained in the chief collections, the other, *Aeranthus distichus*, being simply given as a synonyme. The plant is found growing upon the bark of trees in the neighbourhood of Sierra Leone, whence it was first imported by Messrs. Loddiges about 1835; so that it is an old inhabitant of our gardens, though by no means well known, perhaps owing to its being more curious than beautiful, though the neatness of the plant will always ensure it some admirers. The annexed woodcut represents a branch of the natural size with the flowers near the apex, and conveys a good idea of the chief characters of the plant.

*A. caudatum*.—Another of Messrs. Loddiges' introductions from Sierra Leone, and first appeared in this country about the same time as the one just described. It cannot be considered as hand-

some, but it deserves a brief notice from its singularity. The leaves are pale green, 10 inches long and slightly drooping; the raceme is a foot in length, bearing several flowers with narrow acute greenish sepals and petals, a rounded white lip with a cut margin and green terminal point, and long pale green spur frequently 9 inches long and 2-lobed at the lowest portion. It usually flowers in the autumn, but is rarely seen in good condition.

*A. falcatum*.—A dwarf and pretty species, which is especially interesting from its extending the geographical range of the genus to Japan, a locality widely separated from what might be termed the headquarters of the species. It was originally known under the name of *Limodorum falcatum*; that is before the genus *Angræcum* was established, and under that name it was figured in the "Botanical Register" in 1818. The specimen there represented flowered a month or two previously at Wormleybury in the collection of Sir Abraham Hume, who had obtained it through Dr. Roxburgh. In the following year a plate was also published in the "Botanical Magazine," prepared from a plant in the Horticultural Society's garden. The plant was first observed by Thunberg in Japan on the hills amongst bushes, but he did not record whether it was terrestrial or epiphytal in habit, though probably the latter is the case, as it resembles the other species, and at all events such treatment suits it better in cultivation. As already stated it is dwarf, compact, with narrow leaves, white fragrant flowers of medium size, and an upcurved spur 2 or 3 inches long. Messrs. Veitch exhibited a specimen at one of the Royal Horticultural Society's meetings in 1868, and were awarded a certificate.

*A. fragrans*.—As the only species which possesses any known economical value this may fittingly conclude the list of chief *Angræcums*. It is a native of Mauritius and other islands in that latitude, and is also said to be found in India. In the former it bears the name of *Fahum* or *Phaum*, and owes its utility to the fragrant foliage, said to have "the odour of the Tonka Bean and the flavour of Bitter Almonds." An infusion is employed as a medicine to assist digestion, and is reputed to be efficacious in cases of pulmonary consumption. The plant has been introduced to France, where it is known as *Isle of Bourbon Tea*, and has been successfully employed in medicine. No doubt some collections in England may include specimens of this plant, but I have not seen it in a living state.

The foregoing notes will suffice to give some indication of the range of variation in this peculiar genus; but only some of the most remarkable or best known species have been selected, as the genus is rather large, and has been increased in recent years by the discovery of several forms which are either not in cultivation at present or extremely rare. Among these are *A. articulatum*, *A. Hildebrandtii*, *A. hyaloides*, and *A. Christyanum*, which have all been noticed in the "Gardeners' Year Book" since 1872. Some of these scarce species are undoubtedly attractive, and will probably sooner or later find their way into cultivation.—L. CASTLE.

#### PARAFFIN CASKS.

THE best method of cleansing paraffin casks to render them suitable for converting into plant tubs, is by burning the insides. If one end is removed and an armful of dry shavings is set on fire, the wood, being saturated with oil, will readily ignite. As soon as the oil has been sufficiently burnt out, the flames may easily be extinguished by turning the cask upside down, or by placing a damp sack or piece of matting over the top. The charcoal thus produced on the inside of the cask will assist in keeping the soil sweet when used for plants, and in purifying the water if used for store casks. Paraffin is very searching and quickly penetrates every part of the wood, and no amount of washing will remove it, because the water will not mix with it and cannot penetrate into the crevices. When burning is objectionable the casks should be well scoured out with boiling water, in which a quantity of soda crystals or potash has been dissolved (soapsuds will partially answer this purpose), and when thoroughly dry two or three coats of good paint can be applied; this will have the effect of preventing the oil oozing out for a time, but the moist soil will eventually cause the paint to peel off, when the oil will be sure to appear again.—J. H. S.

WE have here ten of these tubs in use containing the following plants—Two *Cytisuses*, two *Myrtles*, and six *Agapanthus*, all of which have done remarkably well in them. The plan we adopt to cleanse them is to place a bundle of straw inside the tub and set fire to it. We do this as soon as received and before they are cut through the middle. When we think they have burned sufficiently without injuring the tub we turn them upside down,

Fig. 45.

*Angræcum distichum*.

which soon extinguishes the fire.—J. RICHARDSON, *Calverton Hall, Notts.*

[The mode of preparing paraffin tubs for plants has now been made sufficiently clear to all.—ED.]

#### THE BLUE ROMAN HYACINTH.

IN answer to your correspondent "CULTIVATOR OF BULBS," we have only to say that the blue Roman received the same treatment as the white Roman Hyacinth. We find the first bulbs were potted on the 15th October, 1880, and the plants were in flower January 8th, 1881. If they had been potted in August with the whites no doubt they would have been earlier. The foliage is certainly rather plentiful, but so are the flowers, which in our opinion afford ample compensation. We will not fail to remind your correspondent next season when our plants are in flower, nor would we mind sending him a pot gratis if he will favour us with his address.—JONES & SONS, *Coton Hill, Shrewsbury.*

WITH me this is a weedy grower as compared with the white kind—the leaves overtopping and so partially hiding the flower-spikes. This spoils it as a decorative plant, but its flowers are certainly very pretty for cutting. Under precisely the same treatment it is fully a month or six weeks later than the white kind. "A CULTIVATOR OF BULBS" experience of it agrees with mine in all particulars; it may be that we both have had unripened bulbs. If by any possible kind of treatment it can be grown as well as its white counterpart, it will be a most valuable plant. Here *Scilla siberica* is far preferable.—DUBLINENSIS.

#### CULTURE OF VALLOTA PURPUREA.

ALL amateurs who have a greenhouse should grow the old Searborough Lily, as its cultivation is very simple. The plant commences flowering at the end of August, and a few pots of *Lilium speciosum* and album arranged with them would make the greenhouse quite gay during the late summer months. Those amateurs who intend growing it should procure some bulbs at once. The compost employed should consist of turfy loam with a little decayed manure and leaf soil, with sufficient coarse sand to keep the soil open. In potting place three bulbs in a well-drained 6-inch pot; if bulbs are scarce have one in a 3-inch pot, but I recommend the former practice where possible, as the plants will flower profusely and make a beautiful display. In potting place some of the roughest of the compost over the drainage, then three parts fill the pots with soil, and press it down gently to prevent it sinking too much. If 6-six inch pots are used place the bulbs a little distance apart to allow the growth of offsets. Tie the bulbs to a small stick to keep them steady, give a good watering through the rose of a watering can, and transfer the pots to the greenhouse, assigning them a position near the glass, and the bulbs will soon commence growing. Never permit them to be insufficiently supplied with water, and in the summer months they should be sprinkled overhead. When the pots are quite full of roots and the flower stems appearing weak guano water may be given twice a week. After flowering remove the flower stems, as they exhaust the bulb; the pots can then be placed in any sunny part of the greenhouse so as to have the bulbs well ripened. The soil must not be allowed to become dust-dry at any time, not even in the winter months. The *Vallota* is increased by offsets. The small bulbs can be taken in the spring, and are either potted single in small well-drained pots, or placed in pans in a compost of half loam and leaf soil with a little sand, and if placed in a warm part of the greenhouse they will soon produce roots.

One mistake amateurs are apt to make in growing *Vallotas* is in overpotting. To flower the plants well they must be rootbound, and three bulbs in a 6-inch pot will not require a larger pot for three or four years providing the drainage is open. I formerly grew a number of *Vallotas* for conservatory decoration; 10-inch and 8-inch pots were as full of roots as possible, so much so that the pots were frequently burst. With some potting and top-dressing had not been done for seven years, yet the plants flowered very freely; when in flower they were transferred to the conservatory and afterwards returned to the greenhouse, attended to with water, and year by year the same process was repeated. I employed liquid manure made from sheep dung and soot, which I believe are the best stimulants that can be given to plants. I have recommended guano water for amateurs, as it is more easily obtained.—JOHN NUNNS, *Wimbledon Common.*

FUTURE OF GARDENING.—Mr. Roberts' letter at page 151 touches a very important subject with regard to fruit trees, but

he does not allude to a sad item of culture in Devon and Cornwall, about which it may be useful to say a few words. These counties are famed for the production of Apples, but wherever you go now orchards seem to be in a state of decay—all the trees covered with lichens and many prostrate. If a young tree is planted—if the mode of placing them in the ground deserves that term—the site chosen is one overshadowed by old trees. Why is not a new piece of field taken in sometimes? Farmers do not seem to think their orchards of any great consequence; and as for pruning, it appears as if outside their consideration altogether. Probably, if they procured the best varieties, which they do not appear to do, it might prove to their advantage. If culture were attended to we should certainly require less fruit from America.—R. I. L.

#### CARRINGTON MOSS IMPROVED AND CULTIVATED.

ABOUT six miles to the west of Manchester there is in Cheshire a tract of land called Carrington Moss. On the other side of the river in Lancashire there is a larger tract of the same nature known as Barton Moss and Chat Moss. These Mosses were originally almost as soft as a soaked sponge and full of water. To make a line of railway across the two latter puzzled the engineering skill of Stephenson. The materials first used for the foundations were lost, as they sunk out of sight by reason of their weight. At last the difficulty was overcome by employing the branches of trees and hedges. This great swamp is gradually being brought under cultivation and made to yield good crops of grain and other farm produce. First on Barton Moss great ditches or dykes 10 and 12 feet deep were opened, and roads formed between them. Then wedge draining was tried and found to answer well. On soft spongy land such draining is simple work easily understood. Wedge-shaped drains 4 feet deep or more are cut to a point at the bottom. Wedge-shaped fibry sods are cut to fit the drain about a foot from the bottom, and thus an open triangular space is left which carries the water to the deep ditches mentioned. No intelligent farmer or gardener could fail to notice the effect of such draining on visiting a farm there. The removal of the water solidifies the land considerably. Over each drain the land naturally becomes a furrow, and drains at some distance apart make a flat piece of land into a ridge-and-furrow piece. Houses one storey high had to be built on piles. Horses in ploughing and working the land had to wear flat-soled leathern boots, for without them their feet sunk too deeply for work. These uninviting swamps are now being brought under the influence of the farmer and the market gardener. Excellent root crops, Potatoes, Turnips, Mangolds, and Carrots are now produced with corn, hay, and Clover succeeding. The Carrots from the Moss are large, straight, and clean, and Celery grown there cannot be surpassed. The Marrowfat Peas in the dry years of 1868 and 1869 were first-rate.

Carrington Moss, probably four miles long and two broad, belongs to the Earl of Stamford and Warrington, who is fast converting it into manageable and productive land. From the newly reclaimed land the crops are sold annually by public auction at remunerating prices. If such improvements can be made, what might not be done on the peaty boggy lands of Ireland? I think no land there can be worse or more uninviting than this in its natural state.

Carrington village or hamlet is about eight miles from Manchester, three from Sale, and is remarkable for the large orchards attached to the farms of the place. Sale itself, now a large and wealthy suburb of Manchester—at least often considered as such—was once covered with Heather and called Sale Moor, is one of the best places in the north of England for farming and gardening. For these purposes land is readily let at £5 and £6 per statute acre; but the soil here is dry and easily worked, resting on a substratum of sand and gravel.—A. PETTIGREW.

#### LIBONIA PENRHOSIENSIS.

WHEN well grown this is one of the prettiest and most useful plants for flowering at midwinter, and is easily obtained in good condition. March is a good time to insert cuttings, which when rooted may be potted into 60-sized pots and placed in a close frame. In May remove them out of doors to harden-off. At the end of May they may be planted out on a south border fully exposed to the sun, and remain there until September, when they will be neat pyramidal specimens with abundance of glossy leaves. Take them up and pot in 48-sized pots, and arrange them in a close frame until well established. They can then be removed to an intermediate house where the temperature ranges from 45° to 60°, and by Christmas you will be rewarded with hundreds of bright red flowers on each plant. Good plants of

*L. floribunda* may be obtained in the same way; they retain their foliage through the flowering season, but are not so showy as *L. penrhosiensis*.—STIFFORD.

At a general meeting of the ROYAL HORTICULTURAL SOCIETY, held last Tuesday, Sir Trevor Lawrence, Bart., M.P., in the chair, the following candidates were duly elected Fellows—viz., Richard A. Boissier, J. C. Burns, T. H. S. Escott, M.A., James Green, W. A. Hall, T. J. H. Hawkins, Mrs. Lacy, Dr. Alfred Meadows, Robert W. Melvil, Mrs. Osborne, Saul Samuel, C. M. G. Francis, R. Saunders, Mrs. H. W. Trevelyan, Mrs. Wake, Peter S. Yapp, A. E. Young. William Brown and Mrs. Stringer were elected guinea members.

— WE are informed that the Committee and members of the Brixton Hill, Streatham, and Clapham Horticultural Society have recently presented a TESTIMONIAL TO MR. THOMAS TODMAN, gardener to J. Connell, Esq., Bushydown, Tooting, to mark their unanimous appreciation of services rendered by him in the capacity of Judge at their exhibitions from the commencement of the Society in 1859. Mr. Todman has long been known as a most successful exhibitor and skilful gardener, and an eminent hybridiser of florists' flowers, particularly with Azaleas, Pelargoniums, Fuchsias, Verbenas, and Primulas.

— A CORRESPONDENT writes—"I am glad '*P. R., Wigan*,' has brought the single-flowering PELARGONIUM CHARLES SMITH under the notice of the readers of this Journal. There are many fine single Zonals sent out by Mr. Pearson of Chilwell, Notts, and among the best for all purposes is this variety. It is most effective for flowering in winter. The trusses are immense and the colour superb. It is superior to Charles Schwind, although that is a very good one and resembles the one under notice in brilliancy of colour, but is not so free-flowering and the trusses are smaller. All admirers of Zonal Pelargoniums ought to have Louisa Smith and Charles Smith, both raised by Mr. Pearson."

— MR. R. P. BROTHERSTON, writing under date of March the 4th, sends the following upon the WEATHER AND VEGETABLES IN SCOTLAND:—"We are again having severe weather. To-day is the roughest we have experienced this winter. Snow has been falling all day, and a cold easterly wind blowing. Last Saturday morning outdoor work was stopped by snow, and we have been able to do nothing since. On the morning of March 1st we had 15° of frost, the next morning 20°. The only vegetables which passed through the last frost were Broccoli and Celery; even German Greens decayed at the points, Drumhead Cabbages and Savoy's all decayed, and Brussels Sprouts were entirely eaten by pheasants. I did not lose a single Broccoli, having taken the old-tried precaution of lifting the plants and laying them in with heads to the north. A neighbouring gardener, who merely pressed the plants back with a spade without lifting, has had great loss. Cottagers, too, who lifted their Drumhead Cabbages and buried the heads in the ground have saved them. It is impossible to say as yet the extent of damage to shrubs, &c. Laurustinus are all killed, however, and I expect Roses also. Last winter we had 3½° below zero; this winter 2° above zero was our lowest, yet the damage is greater."

— As will be seen in our advertising columns, FIVE HUNDRED ORCHIDS IN BLOOM are to be sold at Stevens' rooms on Friday next. The plants will be on view after two o'clock this day (Thursday), and on the morning of the sale.

— A WRITER in "The Gardener" remarks as follows upon the decorative usefulness of *PTERIS UMBROSA*:—"Considering the great demand for ornamental plants for all sorts of decorative purposes, it is matter for surprise that this most useful and ornamental Australian Fern is not cultivated to a greater extent. It can be grown into large plants in comparatively small pots, and is, consequently, a most suitable Fern for furnishing vases and baskets. It grows, when shifted on into 10 or 12-inch pots, 3 feet high. Its fronds are pinnate, and the lower pinnæ also become pinnate. Its colour is of the most vivid glossy green. A great recommendation to it is that it can be grown in a cool house; and it is singularly free from the attacks of insects, such as thrips, which are so troublesome in the case of many Ferns. It is also a Fern of the easiest possible growth, thriving well in a mixture of loam, leaf mould, and a little sand."

— FRUITS of *SECHIU EDULE* may now be seen in Covent Garden Market. It is the Cho-Cho of the West Indian Islands, where it is cultivated, both the fruits and large fleshy roots serving as food. It is included in the Cucumber family, and does not possess any very distinctive character, being of climbing habit, with yellow unisexual unattractive flowers, and cylindrical fruits tapering from the middle to each end, 4 to 6 inches long and of fleshy substance. They are considered a very wholesome food in the West Indies. The plant has been introduced to Madeira, and fruits are frequently sent thence to Europe. During the past summer a plant at Kew ripened its fruit in the succulent house.

— ON several occasions last year we referred to the new AZALEA MRS. GERARD LEIGH, and we have again to note it as flowering in Mr. B. S. Williams' nursery, Upper Holloway. It is unquestionably one of the best of the numerous handsome amoena type Azaleas, and it well deserves the attention of cultivators. The bright rosy crimson flowers are of neat form, about 1½ inch in diameter, and produced with the characteristic freedom of the race. The plant naturally flowers early, and with a little forcing can be obtained in excellent condition at the dullest time of the year.

— AT the ordinary meeting of the METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 16th instant, at 7 P.M., there will be an exhibition of instruments, consisting of various kinds of hygrometers and of such new instruments as have been brought out since January 1st, 1880. During the evening the President will give an historical sketch of the different classes of hygrometers, and will also describe such forms as are exhibited.

— MR. W. H. SHRUBSOLE, F.G.S., has written from Sheerness as follows relative to GISHURSTINE:—"As an amateur naturalist I do a good bit of shore wading, I was never able to keep the sea water from penetrating my boots till I used Gishurstine. Now I can always keep my feet dry. The article is so good that it deserves a better name."

— THE following are among some recent GARDEN APPOINTMENTS—Mr. James Read, Arley Hall, Northwich, has been appointed gardener to Mrs. Cox, Moat Mount, Mill Hill, succeeding Mr. Beattie; Mr. Alexander Yule, Seaforde House, Co. Down, has been appointed gardener to Mrs. Huth, Wykehurst, Cuckfield; Mr. Daniel Elkins, late foreman at Rendcombe Park, Cirencester, becomes gardener to A. Cator, Esq., Trewsbury House, Cirencester; Mr. Alfred King, Ditton Hill, Surrey, has been appointed gardener to Admiral Thompson, Brynallt, Hertford; and Mr. D. Clements, Westbrook, Sheffield, succeeds Mr. Brake as gardener to C. G. Hill, Esq., Arnot Hill, Notts.

— WE have to record the death of one of the few remaining officers who served in the Peninsular war. Lieut. WM. ANDREWS NESFIELD died at his residence, 3, York Terrace, Regent's

Park, on the 2nd inst., in his eighty-eighth year. Mr. Nesfield was the son of the late Rev. William Nesfield, Rector of Brancepeth, in the county of Durham; he was educated at Winchester, and Trinity College, Cambridge; was cadet at Woolwich in 1809, and joined in the Peninsula, and was engaged in the operations in the Pyrenees. After leaving the army his taste for painting led him to become one of the earliest members of the old Water Colour Society, of which he was for thirty years an active exhibiting member, his contemporaries and friends being Turner, Copley, Fielding, Cox, Prout, and Stanfield. Later in life he took up landscape gardening as a profession, which his education as an engineer at Woolwich and his talent as an artist (as quoted in Ruskin's "Modern Painters") well qualified him to fulfil. In this capacity he was constantly consulted in the improvements and alterations of the London parks and Kew Gardens, and he planned the Horticultural Gardens at Kensington.

— RELATIVE TO THE WEATHER IN NORTH DURHAM  
Mr. P. Ferguson of Monkwearmouth sends the following note: "A week ago we had two or three fine days, and would fain have sung with that genial Scot—'Gloomy winter's noo awa.' But no such luck; ever since Saturday, the 26th February, we have had an almost continuous fall of snow or sleet, with an increasing wind that ultimately developed into one of the most disastrous and terrific gales that have made the present winter so memorable. At the time of writing (5th March) this hurricane of wind and blinding snowstorm has been raging for forty-eight hours without the slightest sign of abatement. With scarcely a furrow turned or a grain of seed sown, with the root crops spoiled in the fields and stock having been hand-fed for over three months, agricultural prospects are indeed miserable in this district. Garden work is also at a complete standstill." Another correspondent writes—"The oldest man living does not remember such an extraordinary beginning of the month of March. The damage done by the frost, snow, and rain has been very great, nearly all kinds of vegetation having been seriously injured; spring-flowering plants are nearly destroyed, and much loss has occurred from damping to Cucumbers and Melons in dung-heated frames, as no ventilation could be given for several days owing to the violence of the wind and the drifting snow. The weather is now milder, a change having occurred on Monday."

### SNOWDROPS.

SNOWDROPS are now in full beauty, and are to be found near almost every country dwelling. Various methods are adopted in planting them, some as if in a wild state, others bordering shrubs. There is another way worth notice, that is planting them in geometrical designs. Under large trees is a very suitable position. A beautiful flower garden could be easily established in the dead of winter. Snowdrops are also useful for table decoration. For a small table a tin about 2 feet 6 inches across should be provided; a round block should be placed in the centre on which to stand the chandelier, or if there is gas a Palm or Dracæna may occupy the centre; the tin should be then filled with tufts of well-flowered Snowdrops. They must have spaces between them filled with moss, which still more improve their appearance. This simple mode of table decoration when tastefully executed cannot fail to give satisfaction.—A. G.

### ROYAL HORTICULTURAL SOCIETY.

MARCH 8TH.

THE advancing season was well shown at Kensington on Tuesday, for the exhibits had so far increased in numbers that, besides several small groups in the Council-room, an unusually fine display of Cyclamens, Amaryllises, Orchids, and miscellaneous plants was provided in the conservatory, the attractions being still further increased by a lecture from the Rev. G. Henslow, and a selection of music by a military band. There was a remarkably large attendance of the members of the Floral Committee, and the Fruit Committee was also

well represented, the meeting altogether proving eminently satisfactory, and notwithstanding the showery weather visitors were fairly numerous.

FRUIT COMMITTEE.—H. J. Veitch, Esq., in the chair. Mr. Sidney Ford sent a dish of a seedling Apple, Margaret Henrietta, a pretty Apple but without flavour. Mr. McIndoe, The Gardens, Hutton Hall, sent a seedling Cucumber called Verdant Green, but the internal colour was so green as to disqualify it. Mr. Douglas, Loxford Hall Gardens, sent a seedling Cucumber from Tender and True, which was considered not quite so good as its parent. Messrs. Cutbush and Son, Highgate, sent samples of Nuneham Park Onion of very fine quality, to which a cultural commendation was awarded. Mr. Strachan, The Gardens, Bulwick Park, near Wansford, sent specimens of Giant Zittau Onion, a fine brown-skinned Onion, to which a cultural commendation was awarded. Mr. Sage, gardener to Earl Brownlow, Ashridge, sent a dish of Musa Cavendishii, remarkably well grown. The bunch had 235 fruits upon it. A cultural commendation was awarded. Mr. Cox of Redleaf Gardens exhibited fruit of Lemons and Oranges from Cyprus, for which a letter of thanks was awarded. Mr. Green, gardener to Sir George Macleay, Pendell Court, Betchingley, Surrey, sent a branch of Coffea arabica var. angustifolia, laden with fruit and showing great luxuriance of growth and superior cultivation. A cultural commendation was awarded.

FLORAL COMMITTEE.—Dr. Denny in the chair. In the Council-room Mr. B. S. Williams, Upper Holloway, exhibited a group of new plants, very noticeable among them being the magnificent Imantophyllum Martha Reimers, which is described below. A specimen of the new Azalea Mrs. Gerard Leigh was shown, respecting which a note will be found in another column. Several plants of Primula sinensis fimbriata alba magnifica were staged, the blooms being of great size and good form. Actinopteris radiata var. australis was represented by a specimen in excellent condition, for which a cultural commendation was awarded. The species is a pretty little Fern very much in the way of Rhipidopteris peltata, and the variety appeared to differ very slightly if at all from the type. The fronds are divided in a fan-shaped manner into linear dark green segments, the stipes varying in height from 3 to 6 inches. Mr. C. Edmonds, Hillingdon, Middlesex, sent plants of Cyclamens, several of which were very fine, especially one named Mrs. Harry Veitch, white with a purple throat, the petals being broad and the flowers numerous. Purple King had flowers of smaller size, of good rich colour, also abundant; good white varieties being Miss Lillian Cox and Charming Bride, for which certificates were awarded. Mr. F. Moore, gardener to C. Pickersgill, Esq., Blandon Hall, Bexley, exhibited a specimen of Lycaste Skinneri giganteum superbum in a 32-size pot, and bearing six large handsome flowers, the sepals broad, and the petals with a rich crimson tinge. The plant was in excellent condition. The same exhibitor also sent a flower of Lycaste Skinneri virginialis, the beautiful white variety of this well-known Orchid. A vote of thanks was accorded. G. F. Wilson, Esq. Heatherbank, Weybridge, sent two cut spikes of Odontoglossum Alexandræ, one bearing thirteen and the other sixteen flowers, which were large, of good form, and with a fine purplish tinge in the sepals. A vote of thanks was accorded.

Mr. C. Green, gardener to Sir George Macleay, Pendell Court, Betchingley, sent flowers of Canna iridiflora var. Ehemanni of great size and deep crimson colour. A note appended stated that the plant from which the flowers had been gathered had been in bloom for the past seven months treated as a sub-aquatic—namely, planted with the crown about 9 inches above the surface of the water in a warm tank devoted to Nymphæas. It is not rested during the winter like other Cannas, and is still flowering, having eight growths about 7 feet high. Fine flowers of the beautiful Vanda Cathcartii were also sent, and a vote of thanks was accorded. Mr. W. Masson, gardener to Dr. Alfred Meadows, Poyle Park, Colnbrook, Bucks, obtained a cultural commendation for a number of large Cinerarias, with flowers of great size and excellent colour, but very loose and of bad form, the plants also being rather coarse. Mr. R. H. Vertegans, Chad Valley Nurseries, Birmingham, obtained a vote of thanks for a basket of double Cinerarias with flowers of good form, chiefly purple and crimson in colour, some having the colours mixed. Mr. James, gardener to Mrs. Watson, Redlees, Isleworth, exhibited a box of extremely fine Cineraria blooms such as he is noted for. They were very handsome in shape, and comprised some rich and varied colours. Two plants were also shown—one, Mr. H. Little, for which a certificate was awarded, and the other Mrs. Little, with flowers of excellent form but of rather peculiar pale purplish tint, or no doubt that would have received a similar award. Messrs. John Laing & Co., The Nurseries, Forest Hill, sent a plant of Begonia Roezli with its small bright coral-coloured flowers. Mr. H. Gohn of the Springwell Nursery, Middlesex, sent plants of Crimson Beauty Primula, the flowers of good colour but rather poor in shape. Messrs. Wm. Paul & Son, Waltham Cross, obtained a vote of thanks for a basket of Primrose Scott Wilson, the plants being in good condition and bearing their purplish blue flowers profusely. J. T. D. Llewellyn, Esq. of Penllergare, Swansea, sent a pot of the diminutive Crocus Sieberi collected at Florence thirteen years ago. The flowers are of a lilac purple tint, and rise about 2 inches above the soil.

In the conservatory as noted above the display was unusually bright, the stage along one side of the entire path being entirely

occupied with large and beautiful groups of plants. The most noticeable were those from Messrs. Veitch, the Orchids and Amaryllises being particularly attractive. Among the former were several specimens of the fragrant *Dendrochilum glumaceum* with numerous spikes of its diminutive flowers. The charming *Angræcum citratum*, recently figured and described in these pages, was represented by a specimen flowering very freely in a shallow pan. The pretty *Dendrobium Ainsworthi* was in good condition, its rich purple-lipped flowers being numerous. One specimen of *D. crassinode* had a growth about 3 feet long bearing twenty fine flowers. Many other handsome Orchids were also observable, among them being several good varieties of *Cattleya Trianae* and *Epidendrum macrochilum album*. A specimen of *Rhododendron Veitchii* was shown with abundance of its beautiful large white crisped flowers. *R. Taylora* was also exhibited in good condition, and near them was a group of *Rhododendron Early Gem*, a dwarf form, with oval dark green leaves and purplish-lilac coloured flowers of medium size, but produced very freely. It appears a useful plant for decorative purposes owing to its dwarfness and floriferousness. Plants of *Guelder Rose* 2 feet high in 32-size pots had a profusion of their balls of white flowers. The double purple *Cineraria* Mrs. Thomas Lloyd was in similarly good condition. *Cyclamens* were contributed in vigorous health, but the Amaryllises were the chief feature of the groups, a large number being exhibited of various shades of colours, some very rich, and the flowers generally of excellent form. A gold medal was deservedly awarded for these fine collections.

Mr. B. S. Williams also obtained a gold medal for a large and handsome group of Orchids, including some fine specimens of *Cypripedium villosum*, one central plant about a yard in diameter having more than three dozen flowers, while several others of less size had from twelve to twenty. *Dendrobium Freemanii* had two growths, each bearing twenty of its warm purple-tinted flowers. Two large healthy specimens of *Phaius grandifolius* had a dozen spikes each. A plant of *Masdevallia ignea* had more than thirty flowers, but rather small, owing to a check the plant had received, as the variety is really a very good one both in depth of colour and size of flower when in good condition. *Cymbidium eburneum* was well shown, also the pretty *Odontoglossum Rossii majus*, and many others which cannot now be particularised.

The General Horticultural Company contributed an attractive and elegant group of fine-foliaged and other plants. Very noticeable were specimens of *Echmea* (Chevalliera) *Veitchii* and *Tillandsia Saundersoniana*. The former has been in flower for a long period, the spike of closely imbricated crimson bracts with their serrated margins being very distinct. The latter has recurved glaucous green leaves with reddish spots, and a large spreading inflorescence of flowers which were not open, but the pale yellow bracts rendered it attractive. Small plants of *Dracæna bella* occupied the centre of the group. This is a charming dwarf variety with narrow crimson leaves, and admirably suited for table decoration, as it colours well in a young state. The elegant *Adiantum Bausei* was in good form; several good specimens of *Nephrolepis Duffii* being also exhibited, with *Aralias*, *Palms*, &c. A silver Flora medal was awarded.

Sir Trevor Lawrence, Bart, Burford Lodge, Dorking (Orchid grower, Mr. C. Spyers), exhibited a very beautiful collection of Orchids, chiefly *Odontoglossums*, some of which had, however, been lent by Messrs. Veitch and Williams to permit the representation of a larger number of species and varieties. More than twenty forms of *Odontoglossum* were shown, some in extremely fine condition; one specimen of *O. Alexandræ* having a long spike with sixteen flowers. The pretty *O. roseum* had seven spikes of its rich rose-coloured flowers. *O. Rossii majus* had five spikes of its large flowers; while the peculiar and distinct *O. Uro-Skinneri* had a long spike of blooms, of which the purple marbled lip is so striking. Among other Orchids was a good example of *Miltonia cuneata* with about a dozen spikes, some bearing ten flowers, *Cymbidium eburneum* being also well represented. A silver-gilt Flora medal was awarded.

*Cyclamens* occupied a considerable space, three good collections being staged—namely, from Mr. H. B. Smith, Ealing Dean; Mr. R. Clarke, Twickenham; and Mr. Charles Edmonds, Uxbridge; to each of whom a silver Banksian medal was awarded. All the plants were in excellent condition and flowering very profusely, the collections differing chiefly in compactness of habit and height of the flowerstalks. Messrs. Osborn & Sons, Fulham, were awarded a silver Banksian medal for a bright group of decorative plants, comprising *Azaleas*, *Cytisuses*, *Spiræas*, *Ericas*, *Hyacinths*, *Cinerarias*, *Richardias*, &c., tastefully arranged. A bronze medal was also accorded to Mr. Aldous, Gloucester Road, for a similar group. Messrs. W. Paul & Son, Waltham Cross, exhibited ten boxes of fine *Camellia* blooms, *Alba plena* being particularly fine, and other good varieties were *L'Avenir*, excellent form, clear pink; *Countess of Derby*, similar but larger; *Reine des Fleurs*, fine crimson, very useful variety; *Ninfa Egeria*, white, good substance and excellent form; *Fimbriata*, white, very symmetrical; and *Mathotiana*, a large flower, rich crimson colour. A silver Banksian medal was awarded. Mr. R. Dean, Ealing, sent some pretty *Primroses*; and a group of plants was contributed from Chiswick, containing a good assortment of useful decorative plants, the fine specimens of *Pteris serrulata cristata major* being especially noticeable.

Mr. S. Ford, The Gardens, Leonardslee, Horsham, staged a very fine collection of Apples and Pears in excellent condition. The

Apples were the most numerous, and were greatly admired for their plump fresh appearance. About sixty dishes were shown, and the silver Banksian medal awarded was well deserved.

First-class certificates were awarded for the following plants:—

*Cineraria* Mr. H. Little (James).—A very distinct and striking variety, quite a new break in *Cinerarias*. It might be appropriately called tricolor, for the flowers have three clearly marked concentric bands of colour, the marginal one about a quarter of an inch wide, deep maroon, the next crimson, and the centre white. The flowers are of good form, about 1½ inch in diameter.

*Primula The Queen*.—Mr. J. Tomkins, Showell Green Nurseries, Birmingham, obtained a certificate for this variety, the flowers of which were fully 2½ inches in diameter, of fine substance and good outline, but not so flat as might be desired. It is one of the Fern-leaved type, of neat habit, the colour of the flowers being white with a slight pink tinge and a yellow eye.

*Phaius tuberculatus* (Sir Trevor Lawrence).—A remarkable and pretty Orchid from Madagascar. The leaves were similar to those marking the genus, but not so large as in the majority of species. The flowers were 2 inches across, in spikes about 9 inches high; the sepals and petals ovate acute and white, the upper slightly arching; the lip was about 1½ inch long and 1 inch broad, constricted in the middle; the base and sides were yellow thickly dotted with a reddish tint, with a tuft of yellow hairs at the base, and the three bright yellow ridges in the centre; the apex was white and pink, with a crisped margin. Four to six flowers were borne in a spike.

*Cyclamen persicum* vars. *Lilian Cox* and *Charming Bride* (Edmonds).—These were two good white varieties, very similar in appearance, but differing slightly in the breadth of the petals, which in both were of good width and substance. The habit was compact, and the flowers numerous.

*Amaryllis John Heal* (Veitch).—Flowers of excellent form; division broad, white at the tip with a band down the centre, deep scarlet at the sides, greenish in the centre. Certainly one of the finest formed Amaryllises that have been obtained; the broad and rounded petals and good general outline rendering it unsurpassed in that respect.

*Amaryllis Royal Standard* (Veitch).—Flowers neat in form and size, similar to the last in colour, but richer and with less green in the centre.

*Amaryllis Miss Alice Gair* (Veitch).—Large flower; broad divisions of a very rich vermilion colour. An excellent variety, and scarcely equalled in brilliancy of tint.

*Asplenium Baptistii* (Williams).—A very distinct species with bipinnate fronds 1 foot to 18 inches long; the pinnæ narrow, serrated, dark green, half an inch broad, and 3 to 5 inches long. The plant is a native of the South Sea Islands, and was introduced about two years ago. It was certificated by the Royal Botanic Society last year.

*Imantophyllum miniatum Martha Reimers* (Williams).—A noble variety of *Imantophyllum* obtained by Mr. Williams from the Continent. The plant shown had fine rich green leaves 2 feet or more in length; two umbels of flowers, one on a peduncle 2 feet in height and comprising nearly thirty large blooms. The corollas are 3 to 4 inches long, brilliant orange scarlet, with a lighter centre. We give the name as rendered by Mr. Williams, but we presume the variety is the same as that figured in the "Flore des Serres" last year as *Marie Reimers*, and which was one of several in Van Houtte's nursery, raised by M. Theodore Reimers, gardener to Madame Donner, near Hamburg.

SCIENTIFIC COMMITTEE.—Mr. Schofield gave some account of an experiment of M. Alfred Dumesnil, who grew in baskets for ornamental purposes a number of plants without earth, but surrounded with moss and apparently in some nutritious matrix. They were exhibited in The Square, Solferino, at Rouen. Mr. W. G. Smith exhibited cut blossoms of *Narcissus Tazetta* var. *floribundus* growing wild (naturalised) at St. Michael's Mount, Cornwall, flowering three months earlier than near London. He also exhibited "Jew's Ears," *Hirneola Auricula-Judæ*, gathered from semi-decayed Elder branches at Ely. Mr. Maclachlan reported on the Wheat culms attacked by some insect, and considered peculiar that it should be a Chalcid—a parasite, there being no evidence of the usual host—a dipterous insect—having previously attacked the Wheat. Rev. H. Crewe exhibited *Galanthus Redoutii*, *Shaylockii*, *spirescens*, and a small species with a yellow ovary, probably *reflexus* (?). Mr. Pascoc exhibited twigs attacked by a *Thelephora* from Pava, Brazil. Dr. Masters exhibited a specimen of Hazel with an enormous protuberance caused by hypertrophy, possibly due to overpruning. He also showed galls on *Picea polita*, the Japanese Spruce; also a remarkable malformation on the calyx of *Eucalyptus*, in which the five lobes had become separated. It was forwarded by Baron von Müller. Proliferous flower of Foxglove, from Dr. G. Bennett of Sydney, with the corolla regular, from the centre of which the shoot proceeded. Mr. Boscawen forwarded *Narcissus triandrus* and a leaf of Paris Daisy undermined by the larva of a moth.

LECTURE.—The Rev. G. Henslow first alluded to a fine group of Amaryllises exhibited by Mr. Veitch, and made some remarks upon the order Amaryllidæ to which it belongs. He spoke of the uses to which *Agave americana* is put, as for fibre and an intoxicating drink, &c., while *Hæmanthus toxicarius* supplies a poison to the Hottentots. The common Daffodil is also said to be extremely poisonous. He next entered on a description of the principles and methods of fertilisation of flowers, describing the structure of stamens

and pistil with the view of illustrating the process by Orchids, of which Messrs. Veitch, Sir Trevor Lawrence, and Mr. Williams contributed very fine groups. He first pointed out methods of attraction afforded by plants to insects in order to secure fertilisation by intercrossing, that although the corolla or the perianth was the normal organ, yet bracts and calyx were sometimes utilised by being brilliantly coloured. *Anthurium Schertzerianum* and *A. Andreanum*, as well as *Tillandsias* illustrated this peculiarity. This change of function, so to say, often took place, and at the same time illustrated the principle of compensation, by which one organ undertook the functions of another, not infrequently becoming modified accordingly. Some plants of Guelder Rose and double Cinerarias were taken to illustrate this, to

which corollas had grown abnormally at the expense of the essential organs, or stamens and pistils; a plant of *Xylophyllum* with flattened branches superseding leaves also showed the same phenomenon. Mr. Henslow then proceeded to describe the structure and method of fertilisation of several Orchids, such as *Phalænopsis*, *Dendrobium*, *Cattleya*, and *Coryanthes*, principally following the details as explained by Mr. Darwin in his work on the "Fertilisation of Orchids."

#### VIOLET "ODORATISSIMA."

MR. CANNELL of Swanley has sent us blooms of the above variety of remarkable size and substance, and deliciously perfumed.

Fig. 46.—VIOLET ODORATISSIMA.

Last year Mr. Abbey wrote as follows on this Violet:—"It has fine blooms, freely produced, and very sweet; it greatly surpasses the Russian, Czar, Giant, single white and single red." The flowers we have received confirm that statement. They have also very long and stout footstalks, which add greatly to their "bunching" and using in bouquets. How far the soil of Swanley has contributed to the production of such fine flowers and how much of his "invigorator" Mr. Cannell has given to the plants we know not, but larger and more fragrant Violets we have never seen. The annexed engraving by Mr. Smith, which we have obtained from Swanley, shows this excellent variety in good condition.

Some of the flowers sent to us were more than  $1\frac{1}{2}$  inch across and of a bright pleasing colour. Many of our readers, we doubt not, will endeavour to produce flowers of Violet odoratissima similar to those represented, and they may succeed with young plants established in good soil and a suitable situation.

CINCHONA CONSUMPTION.—A writer in the *Colombo Observer*, referring to this subject, says:—"I do not think I am overestimating the number of Cinchonas that will be planted in 1880 throughout the island at 20,000,000; allow 5,000,000 for failures,

and add 5,000,000 for plants planted in previous years and now alive, and it will give you 20,000,000 Cinchona trees, which in five years will yield, either by taking strips and mossaing, or by the shaving process, about 10,000,000 lbs. of dry bark a year." Mr. Ferguson, in his *Ceylon Directory*, estimates the production of Cinchona bark for the world at 13,471,000 lbs., of which Ceylon is put down for 150,000 lbs.; "but when," remarks the correspondent referred to, "it produces 10,000,000, as I believe it will in 1885, the total production of the world will exceed the demand of 1876-78 by 10,847,000 lbs. The question therefore arises, Will the demand for Cinchona bark in 1885 equal the supply, or will the bark become unsaleable except at unremunerative prices?"

## KITCHEN GARDEN.

WITH March a busy season usually commences, but the presence of snow in many localities, and the unfavourable state of the ground for the reception of seed, will necessitate prompt attention in preparing it at the earliest opportunity. Onions and Parsnips should be sown as soon as possible, also good breadths of Early Horn and James's Intermediate Carrot, reserving the main sowing for winter use until April. Leeks also should be sown when the ground is in a fit state. Sow early Turnips—Early Munich is valuable. Lettuce and Radishes from this time forward should be sown about every three weeks. A successional sowing of Peas and Broad Beans must also be made, sowing some of the early Peas when the main crop kinds are commenced with, so that there may not be any break in the succession. Where the soil is not heavy and the snow has gone Asparagus beds may be lightly forked over, and the alleys prepared for planting with Cauliflowers. When the requisite quantity of Asparagus roots are taken up for forcing a corresponding number of roots should be planted annually, deferring the planting, however, until the tops of the seedlings are visible, as they succeed best when starting into growth. Complete planting out Horseradish. Spinach may be sown between the rows of Peas.

## FRUIT HOUSES.

*Figs.*—The earliest forced Fig trees in pots will now have the fruit swelling freely, and should be well supplied with liquid manure at a temperature of 70° to 75°. Continue the night temperature at 60° to 65°, and 75° to 85° from sun heat with free ventilation, closing at 80°. Syringe the trees twice a day to keep red spider down, also to secure a genial condition of the atmosphere. Fig trees permanently planted out will, if forcing was commenced as advised, be making rapid growth, and will require attention in removing all overcrowded shoots and stopping those intended to make well-developed spurs for the second crop. This thinning and stopping the shoots is highly necessary, as it renders the trees more fertile and affords more light and air to the swelling or ripening fruit. There must not be any deficiency of moisture in the border, supplying weak tepid liquid manure abundantly.

*Peaches and Nectarines.*—In the earliest house the fruit will shortly commence stoning, during which period the temperature must be kept as equable as possible, being careful not to unduly excite the trees by a too high night temperature, nor give a check by draughts of cold air in the daytime. The night temperature may range from 60° to 65°, and 70° to 75° in the daytime from sun heat. Attend to tying the shoots to the trellis as they progress, and syringe twice a day with tepid rain water to keep red spider under; and if it appear promptly apply an insecticide, for under no circumstances must this pest be allowed to remain. Disbudding must be carefully attended to in succession houses, removing those shoots that are not required, having the leading shoots tied down, taking care not to overcrowd them. Thin the fruit gradually, leaving those in sufficient quantity that are well exposed to light and air until the final thinning. Fumigate the trees upon the first appearance of aphides.

*Melons.*—The first batch of Melon plants in houses will now be growing well, and should not be stopped until they have advanced quite two-thirds of the distance they are intended to be trained. To prevent crowding every alternate lateral should be rubbed off. Fruit may be expected at the second or third joint on the laterals. When the pistillate flowers are expanded fertilise them every day, having the soil rather dry at the roots of the plants, and secure a dry atmosphere, continuing this until the fruit commences swelling, then stop the shoots one joint above the fruit. To obtain a succession of fruit remove all the flowers from some of the plants and stop the laterals at the second or third joint, removing every alternate lateral, and these will break again and show fruit freely. Do not earth up the roots until the fruits are swelling, first giving a thorough soaking of water, and moderate amount of soil only will be necessary to grow the first batch; and the crop also must be moderate if the plants are intended to carry a second, two or three (at most four) fruits to each plant. Maintain a moderately moist atmosphere in bright weather by damping available surfaces morning and evening, and a gentle syringing overhead at closing time, which should be as early in the afternoon as is safe, and so as to raise the temperature to 85° or 90°. Ventilate from 75°, but be careful in giving air so as not to lower the temperature, nor admit cold currents of air; 70° to 75° should be maintained by day artificially, falling 5° on cold nights.

*Cucumbers.*—The weather at the commencement of the month was very winterly, rendering extra firing necessary to maintain the night temperature between 65° and 70°. In the daytime 70° to 75° must be secured, and 80° to 85° with sun heat, ventilating from 75° and closing at 80°, when the house should be damped and the foliage lightly syringed, but the latter only on fine afternoons. On bright days the top heat should be turned off for an hour or two at midday to lessen the necessity for excessive ventilation. Stop the growths one or two joints beyond the fruit. Thin out old foliage and encourage fresh shoots, but be careful not to overcrowd them. Water will be needed more frequently, and liquid manure occasionally, according to the condition of the plants. Those becoming exhausted may be restored by removing the surface soil between the roots with a small fork, supplying fresh loam previously warmed, following with a supply of weak liquid manure at 90°. The cold weather lately experienced will render it necessary to apply linings to dung-heated beds made up a few weeks ago. When the bed is reheated be careful to allow the escape of steam, especially when the sun is powerful. Add a little more soil as the roots spread over the surface; water carefully, and do not damp the foliage at present. Train and peg down the shoots at the joints as they advance. In making up hot-beds in pits or frames the materials must have been thoroughly incorporated and prepared by repeated turnings. For frames choose a sheltered situation, but well exposed to the sun. If the situation be wet employ a good layer of faggots as a foundation, and have the bed not less than 20 or 24 inches wider than the frame on all sides, and carry it up about 4 feet above the faggots, treading it well down as it is made. The frame may then be placed on. In about a week the bed may be levelled, a thin layer of turves being placed grass side downwards over the surface, and in the centre of each light raise a hillock of soil about 10 inches high and with a flattened top a foot across. When the heat in the hillock is from 85° to 90° the plants may be put out. Night coverings will be necessary to maintain a suitable night temperature of 65° to 70°.

## MUSHROOM HOUSE.

Beds made-up in early autumn are now exhausted and should be renewed. Fresh materials may be prepared by shaking out the fresh horse droppings from the litter with any short material. There is no necessity to dry it unless very wet, and then it should be spread on the floor of an open airy shed, or thrown into a heap to dispel excess of moisture by fermentation, turning it over about twice a week. When the excessive moisture is expelled it may be made into the bed, treading and beating it as firmly as possible. In a few days the bed may be spawned, but if the heat exceeds 90° wait until it declines to between 75° and 80°. Make holes at 9 to 12 inches apart every way and 2 inches deep, inserting in each a piece of spawn about 2 inches square. In a week or ten days cover with 2 inches thickness of rich

turfy loam, beating it firmly and smooth with the back of the spade. In about six weeks Mushrooms will appear, when careful sprinkling with tepid water will be needed to keep the surface moist. Beds that are becoming exhausted may be improved by a good soaking of liquid manure at a temperature of 100°.

## THE BEE-KEEPER.

### SEASONABLE HINTS.

[THE following hints were prepared before Mr. Cheshire's calendar for March appeared last week. But I venture to think their insertion may still prove seasonable, especially in these northern parts where winter still holds unmitigated sway.—W. R.]

NOTWITHSTANDING the almost arctic severity of the winter, stocks that have been properly prepared have generally wintered well; that is to say, they have come through thus far with comparatively little loss of strength or waste of stores. In inland localities where the frost has maintained its hold till now, and the snow is still deep, the opportunity for a cleansing flight has occurred so seldom that soiled combs are found in a good many hives, generally, however, in those only that had not been sufficiently contracted to enable the bees to keep the whole interior warm with an ordinary consumption of food. A hurried examination a fortnight ago showed that nearly all my stocks had patches of brood in all stages and many of them young bees—a proof that breeding can go on even during a period when the external temperature is frequently below zero.

There is considerable danger in making the necessary overhaul of stocks after a long period of confinement. If the first fine day be taken for this purpose, as is very generally recommended, the very act of opening the hives will cause the bees to sally forth with such haste that, failing to mark their locations as they ought to do after a long confinement, many will return to the wrong hives, and thus endanger the lives of the queens. The large number of cases of queen-encasement observed during or after such commotions is entirely owing to the presence of strange bees in the hives, and not, as Mr. Abbott so ingeniously suggests, with a view to exciting the queens to lay eggs. Certainly, where any suspicion of short stores exists, the first opportunity must be taken of certifying whether or not food is required; but there need be no disturbance caused by so doing. It is only necessary, as late in the day as possible, to turn back the quilt without any smoke until the cluster is reached. A hurried glance at the top of the combs will show by the amount of sealed honey visible whether anything further requires to be done. In cases of necessity nothing is so good at this season as well-made candy cake with or without flour. Having a supply at hand in thin slabs, one of these can be quickly pushed under the quilt.

A more thorough overhaul should be made after the bees have had a flight on several successive days. With as little disturbance as possible notice must be rapidly taken of the following points—viz., the amount of stores still available, the presence or absence of a queen or brood, the amount of dead bees or *débris* on the floorboard, the condition of the combs as to dryness or mouldiness, and, in localities where foul brood may be suspected, whether any trace of it is visible in the combs. If it be possible to remove any combs, so as to confine the bees into less space, this may be done at the same time; but if there are many hives to go over, other requirements should be merely noted down to be attended to when all needful appliances may be ready to hand.

Such an examination is very interesting, presenting as it does in every separate stock a different problem for immediate solution. What to do with queenless stocks or with those having queens we wish to save and which are yet too weak to risk longer as they are, how best to supply the want of honey or pollen, how to deal with the first discovery of foul brood, and generally how to assist every stock in maintaining or increasing its strength as much as possible—such are some of the questions that thrust themselves all together on one's attention. The limits of this article forbid my giving more than the following hints.

1, Contract the brood nest by removing all combs which the bees cannot cover, and closing in the division boards. 2, Maintain the chaff packing until the bees have increased to cover six or eight frames. 3, Supply flour candy to keep up breeding until natural pollen is being gathered, after which commence syrup feeding in small quantities, and give pea flour in the open air. 4, Transfer from damp or soiled hives to clean ones, and give clean combs where these are available. 5, Clear out dead bees and

*débris* from all other hives. 6, Put bees of infected hives on clean combs or sheets of foundation after twenty-four hours quarantine, and feed with both syrup and flour candy which have been treated with salicylic acid. Melt up all infected combs, scald and fumigate hives and frames, and take care that no other bees do any robbing while doing so. 7, Join queenless bees to the nearest stock by shaking all the bees from both stocks into a common box, afterwards running them in as a swarm, and caging the queen for twenty-four hours. 8, Pack weak stocks into a common hive with only a thin partition between, giving separate entrances. When one of the queens is required elsewhere, remove the divider and allow the stocks to amalgamate.

It is to be borne in mind that from this time forward, probably till April, the strength of our stocks may be expected to decrease steadily, owing to the loss of old bees exceeding the gain from breeding. Consequently everything should be done that tends to husband their strength. Entrances should be contracted and shaded when snow is on the ground; as little disturbance as possible should be made; heat should be economised by means of warm packing and necessary supplies of saccharine food; pollen substitutes and water should all be at hand to save the bees from the necessity of taking long flights in uncertain weather. Now is the time to get hives, supers, and other supplies in readiness for the day of need, also to provide seeds of honey plants—of which I last season found the yellow Melilot by far the most profitable. At the time of sowing, attention should be given to making everything about an apiary as tidy and attractive as possible. I could tell of wondrous arrangements in the marine store line that I have witnessed in some apiaries, but at present the hint may be sufficient. It seems as if foul brood were about to become epidemic in some districts. Various correspondents have recently informed me of serious outbreaks in Ireland and some parts of Scotland. It ought to be specially guarded against, and no pains spared to stamp it out on its first appearance.—WILLIAM RAITT, *Blairgowrie*.

### HOW TO USE THE EXPANDING AND CONTRACTING CAPABILITIES OF BAR-FRAMED HIVES TO THE UTMOST PROFIT.

THE discovery of the great value of expansible hives is a marked feature in the progress of scientific bee management. For many years this principle has been gaining in favour with all but the fixists. Nay, even they—some of them—have adopted the principle in regard to supers, enlarging super-space over a hive by a kind of telescopic movement upwards, thus gradually elevating the super. The objection to this particular adaptation of the principle of hive-expansion lies in this, that it tends to the production of unsaleable honey in unwieldy boxes; but if quantity alone is the profit aimed at, and not money value, this adaptation is excellent. We are now, however, dealing with laterally expanding bar-framed hives. Last year one of these in my garden containing sixteen frames, to which the bees were gradually admitted by removal of the dummies, was found to have filled every available space from end to end at the end of June, but the central combs were too full of pollen. The brood cells were found in quantity in the combs at each end of the hive, but comparatively few in the six or seven intervening combs. Not so an adjoining hive, which was exactly similar in all respects, the queens being both hybrid Italians of the same age, and having begun the year with a population little if at all greater the one than the other. Both hives, in fact, were still somewhat weak in numbers at the beginning of May. In the case of the second stock the combs were pretty evenly filled with brood throughout, nor was there much pollen. Incidentally I would notice that this shows we cannot manage our bees on any plan which shall produce a uniform effect. Start two hives side by side as fairly even in all respects as can be done, and in the course of the season the results of their procedure will widely vary. Hence it is I never can believe in any reliable estimate as to the relative value of hives coming out of such trials as are proposed from time to time.

I have, however, instanced the case of these hives because the excessive quantity of pollen in the one was, I feel assured, a main reason why it disappointed me as regards the quantity of honey obtained from it, and set me thinking if there was any remedy to be found. Would it have been possible to baffle the bees, and to make them gather honey instead of storing so much useless pollen—useless at least at that particular time, which was the very height of the splendid honey harvest of last summer? What if I had removed all these combs, putting them by for use later on; and what if I had contracted the brood nest to, say, the nine or ten combs actually filled with brood, while giving them plenty

of super space above the hive, and perhaps also nadir room below? Would they not have taken to the supers in force, being compelled to move up there from sheer lack of space, and given me a splendid lot of beautiful honeycomb, especially if I had kept out the queen? I did take a considerable quantity of honey from this stock in spite of its having swarmed during my absence from home in July, but nothing to what I ought to have got from it. It is hardly likely either that they would have swarmed if they had taken kindly to a number of supers just when the honey glut came on. Moreover, as the young bees issued from the combs below, most of these latter would be filled with beautiful honey hardly less inferior in quality to that stored in the supers, because these combs were all of quite recent construction. Then, at the close of the season, when the final plundering took place, any hives that were deficient in bee bread would have gladly welcomed the pollen-filled combs, some of which might have been returned to the parent hive in place of some of the sealed honeycombs found there. We all know how frequently the supply of pollen is deficient in autumn and early spring in some hives, so that it has even to be supplied artificially.

It will be seen that this idea of treating an expanding bar-framed hive tallies in the main apparently with Mr. Cheshire's suggestion, but only in the particular case of a superabundance of pollen in those combs which are to be "removed." I do not know if he was thinking of pollen-filled combs or what he would recommend to be done with the combs thus removed. The only other combs not filled with brood would be more or less filled with honey. I hardly think these should be removed.

However, I ventured to suggest a quite different treatment of the hive, and to this I now come. This, too, occurred to me in consequence of the state of the pollen-filled stock just referred to. It occurred to me that such a hive might be profitably treated in the following manner:—First remove all combs that may be overfilled with pollen, which (after slinging out all the honey that may be found in the open cells) should be put carefully by for subsequent use as before mentioned. The bees will first have been swept back into the hive after capturing and removing the queen, and she must be sought for and destroyed upon whatever comb she may be found; at the same time let every semblance of a royal cell that may be found in any part of the hive be cut carefully away. Next after removing the pollen-gorged combs take out in the same way those frames which are fullest of sealed broodcomb, to be treated as I shall presently advise.

By means of this comb-removal the brood nest in the hive will probably be narrowed to some seven or eight combs out of, say, sixteen. The dummies can then be introduced and all lateral comb-making will cease, while the bees will be driven to work in such supers as the bee-master may find it good to place over the hive, according to the requirements of the particular stock.

The result of this treatment will first of all be apparent in the arrest and defeat of all immediate swarming intentions. In the next place the bees, not having any call upon their time beyond attending to the brood actually existing in the hive, will, for a fortnight at least, have their attention increasingly, and at last solely, devoted to the ingathering of honey, which, for lack of room below, will all be stored in the supers. At the end of that time of course swarming must be looked for as soon as the artificially reared queens begin to pipe; but an overhaul of the hive and an excision of all royal cells after the issue of the first swarm will restore matters, leaving the whole of the bees for perhaps another fortnight to the undisturbed collection of honey. I presume, of course, that the swarm with its young queen is immediately returned to the hive.

As for the sealed broodcombs which were removed from the hive, they can be utilised with much advantage for the strengthening of some weaker hive, of which there are sure to be some in every apiary. Their removal would, of course, be unnecessary in any other case save where it is desired to force the bees into supers. As the young bees in them would in the course of a fortnight mostly have left their cells, it is plain that the bees would at once proceed to fill these cells with honey as they become untenanted, to the diminution of the stores which would otherwise find their way into the supers.

At the close of the honey season it is obvious that in a stock treated on this plan—the young queen being ready and eager to breed—the bees would require pollen in increased quantities. Here, then, it might be advantageous to return some of the pollen-filled combs before removed; and these might be substituted in place of others that were full of honey.—B. & W.

#### A GERMAN APIARY.

AFTER the close of the Exhibition, which has already been described, my friend and myself (for I was accompanied from London

by Mr. S. Stutterd of Banbury, who is conversant with the German language) started on a little tour into the country districts in order to obtain some insight into the mode of keeping bees in Germany.

Our first call was on Mr. A. Schlösser at Ehrenfeld, near Cologne, who was awarded a silver medal at the Congress for his large collection of honey and splendid colonies of bees (to whose exhibits at the Show reference has already been made). He is a fruit-grower on a large scale as well as an apiarian, and has a commodious house and garden. We were at once conducted to his bee-house, which is in the form of a cross, having four doors. Each one of the four wings projects nearly 11 feet, and is the same in breadth, which adding the space of the interior, gives a diameter from door to door of about 33 feet. One half the space of the interior is required for the necessary manipulations, the other half to the right and left is occupied by the hives. The first shelf is about 2 feet from the floor, the second tier is the same distance above, and the third is 2 feet higher. The hives are "Mehring's" twin-frame hives, and of much the same construction as Dzierzon's, except that the colonies are side by side, not end to end as is the case with the latter. Each shelf accommodates four twin stocks, so that the openings are cut in the boarding for eight entrances; thus there may be twenty-four colonies on each of the eight sides. This pavilion therefore holds when filled 192 hives of bees. At the time I was there many hives were away at the moors, consequently only a few were to be seen. The house is closely boarded and has a tiled roof. There is no admission of light except when the doors are thrown open. The hives open at the back, and are therefore easily manipulated without molestation by robber bees. Escape for any bees that are outside the hives is found through the open door.

There is plenty of space to work the extractor in the centre of the building. On inquiring if there was an apparent difference in the prosperity of the colonies facing the different aspects, Mr. Schlösser said that those exposed to the afternoon and evening sun, which induced the bees to fly out again, are placed in the most unfavourable position; but as long as the entrances are not exposed to the direct rays of the sun it makes no difference whether they face north, south, east, or west, and the only drawback which he finds to his "pavilion" is, that when quite filled the colonies are placed in too close proximity, which causes the loss of many queens in their return from their wedding flight.

This is an objection that might be expected, and favours our English plan of keeping hives on separate stands in the open. The German arrangement has an advantage in being able to keep a large number of stocks compact in a comparatively small space, and is likely to secure them from the risk of being stolen.

We visited some other apiaries in adjacent towns, but there was nothing very special to report, the construction of the hives being much the same as those before mentioned. At Zulpich we called on Mr. Schmidt, a tanner, who is also a bee-keeper; he received us very courteously, and learning that we wished to see apiaries in the locality, he not only showed us his own, but gave up some considerable time in escorting us to others. We learned from him that a bee-keeper in this neighbourhood had taken 1330 lbs. of honey from sixty stocks. This, however, was far excelled by an apiarian in this country, Mr. Alfred Rusbridge of Sidlesham near Chichester, who informed me at the Dairy Show at Islington that he had taken the enormous quantity of 19 cwt. of honey and honeycomb from twenty-five stocks of bees. It may be inferred that the quality was fine from the fact that his exhibits were awarded two first prizes. I may mention as a singular contrast, that in the season previous (1879) this gentleman was unable to take an ounce of honey from his apiary.

The past season seems to have been a favourable one in Germany as it has in this country, and we mostly found that bee-keepers were encouraged by their success. After much interesting conversation we took leave of our friend Mr. Schmidt, and on my companion apologising for occupying so much of his time, he replied that it had afforded him much pleasure to accompany us; for, said he, "I can work every day, but could not have the happiness of receiving visits from English bee friends every day." We left by rail for Aix-la-Chapelle, thence on to Brussels, and spent a day at the Exposition, with which we were much interested, but found no exhibits of bees. The display of machinery and manufactures was large, and considering that the Exhibition was purely national it certainly did great credit to Belgium, and was well worthy of a visit.—ALFRED NEIGHBOUR, *Regent Street, London.*

#### TRADE CATALOGUES RECEIVED.

George White, Carriagehill House, Paisley.—*Catalogue of Florists' Flowers.*

Cranston Nursery and Seed Company (Limited), King's Acre, near Hereford.—*Descriptive List of New Roses for 1881.*

J. Coombs, The Ferns, Enfield, Middlesex.—*List of Cuttings for 1881.*

Messrs. S. Ware, Hale Farm Nurseries, Tottenham.—*Illustrated Catalogue of Choice Hardy Perennials, and List of Hardy Florists' Flowers.*

Casbon & Son, Millfield, Peterborough.—*A List of Zonal and Fancy Pelargoniums.*

\* \* All correspondence should be directed either to "The Editor" or to "The Publisher." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Books** (*Inquirer*).—Miss Pratt's works are, we think, published by the Society for the Propagation of Christian Knowledge. The "Cottage Gardeners' Dictionary" can be had from this office, price 6s. 6d., or post free 7s. 2d. The "Horticultural Directory" is published annually in the autumn, price 2s. The last edition has been long out of print.

**Culture of Sarracenias** (*Young Gardener*).—You will find the information you require in No. 20 of the third series *Journal of Horticulture*, November 11th, 1880.

**Primulas** (*J. P. B.*).—The dark flower is of good form and substance; the colour is also deep, but brighter and richer flowers are in possession of the principal florists who devote special attention to Primulas. The lilac and white fimbriated flower is attractive, but not novel; the others call for no comment.

**Prolific Cucumber** (*J. J., Lancashire*).—The variety is evidently highly productive. The portion of growth sent, which is less than 6 inches in length, contains three joints and thirteen embryo fruits. Mr. Smeatham also appears to grow Cucumbers well.

**Cinerarias** (*J. H., Sussex*).—Some of the colours are particularly bright and rich, and most of the flowers are of good size, form, and substance. It is a good strain if the plants are of dwarf habit.

**Pelargoniums** (*T. M.*).—It is impossible for us, as we have many times stated, to recommend dealers either in plants or any garden requisites. If you write to those who advertise what you want they will no doubt quote special prices for large quantities, but it will be necessary for you to state your requirements more clearly than in the letter before us. You must state what type of Pelargoniums you require, and what class of plants.

**Heating Garden Structures** (*J. E.*).—By a proper arrangement of pipes and valves all your houses may be heated safely and efficiently by one boiler placed in the position you propose. If you are not practically acquainted with heating garden structures you will do wisely to employ someone who is competent in this work. With the feed cistern of the boiler on the same level with the highest point in the hot-water pipes the circulation will be free, the pipes being properly arranged, and all will be perfectly safe.

**Planting Ranunculus** (*Willesden*).—The present is a good time for planting, and there should be no unnecessary delay. The soil should be in fertile condition, fresh loam being added if needful, which is better than rich manure applied at this season of the year. Drills about 5 inches apart should be drawn for the tubers, which should be planted 3 inches apart in them, pressing them down slightly in sand, and surrounding them with the same material. They should not be covered more than 1½ inch deep with light soil.

**Vines Unhealthy** (*H. L.*).—The few roots sent are quite insufficient for a satisfactory investigation to be made respecting the cause of the unhealthiness of your Vines. We shall require four times the quantity, especially of the ends or fibrous portions, of which you have not sent any. They should also be wrapped in damp moss so as to arrive in a fresh state, those before us being quite dried and shrivelled. We believe there is some injurious substance in the border. As so much time has elapsed since you wrote to us before it will be necessary for you to re-state your case by informing us fully on the age of the Vines, the conditions under which they are grown, and the nature of the soil and state of the border. Owing to the great number of inquiries we receive on various subjects from all parts of the kingdom it is impossible that we can keep in mind the particulars of each case for several weeks after it was brought before us.

**Disbudding Vines** (*J. M. B.*).—Your sketch shows what we meant, but you must particularly avoid overcrowding of the foliage. The distance named is sufficient for Vines in a sound healthy condition; if very vigorous, and with unusually large foliage, the distance between the laterals may be increased. It does not follow that each lateral must carry a bunch of Grapes. We had in mind the shortness of the rods when we replied to your letter, and to thin out the laterals as you propose at once would not result in the thickening of the rods so much as is desirable. Commence as we have suggested, which will encourage root-action, and another year dispose the laterals according to their strength; but a final distance of 2 feet will with such short rods, we think, be ample, but everything depends on the vigour of the Vines and the foliage. If you will send us an average sample of the wood and foliage in the autumn we will readily advise you further on this subject.

**Raising Camellias and Azaleas from Seed** (*F. W., Isle of Wight*).—You will not find it profitable to raise plants from seed. When the seed of Camellias is saved from single varieties you can only expect singles in return; but if saved from good semi-doubles some double flowers may be expected. The time at which the seedlings flower depends entirely on the culture they receive; with your conveniences they would probably be as long as you name or nearly so. Cuttings of free-growing varieties make as good stocks as seedlings, but you will find it much more profitable to purchase small worked plants than to attempt raising stocks and grafting them yourself, as in all probability you would only be wasting time by endeavouring to do the work of a skilled propagator who has proper means at his disposal for carrying out his work success-

fully. We have flowered seedling Azaleas in four years, but had better means of growing the plants than are at your disposal; in fact you do not appear to be in position for carrying out your project.

**Abutilons from Seed** (*Idem*).—Plants raised from seed sown in the spring usually flower the same season if they are grown in pots under glass. You will not be able to preserve the plants if you cannot protect them from frost during the winter.

**Ericas** (*Constant Reader*).—It is impossible for us to give useful replies to correspondents who request us to name good varieties of plants without knowing, at least approximately, the number they require. You give us no idea whether you want a dozen or fifty. If you will state your wants more precisely your letter shall have our attention.

**Primula sinensis fimbriata** (*R. L. Quinn*).—We are unable to decipher the most important word in your letter. If you wish to know how to "save" seed you cannot do better than place the plants on a shelf in a greenhouse where the atmosphere is dry, and water them as carefully as if they were flowering; in due time seedpods will form, and when these turn brown they may be gathered. Plants that flower late—from the present time onwards—usually seed much more freely than those that flower in midwinter, as during the dull period of the year the pollen does not become sufficiently dry for dispersion and fertilisation. If you desire to know how to "sow" the seed, drain the pots well and fill them nearly full of light sifted soil, such as decayed vegetable matter; do not press it firmly; water it, sprinkle the seed on the surface, cover it very slightly, lay a square of glass over the pot, and keep it shaded until germination takes place, then admit light and air gradually to promote the healthy growth of the seedlings. A heated frame is a good position for raising Primulas during the early months of the year.

**Planting Vines** (*E. A.*).—You had better keep the Vines quite cool and allow them to break naturally. When they have fairly commenced growing turn them out of the pots, removing all the soil from the roots, which spread out straight in the form of a fan, covering them 4 or 5 inches deep with fresh loam and a free admixture of burnt refuse or wood ashes, and mulch the surface with short manure. Immediately after planting give a good watering at a temperature of 120° to settle the soil amongst the roots. Do not force them. A night temperature of 50° will be sufficient for three weeks after planting, then raising it to 55°. When the Vines are in full growth the night temperature may range from 60° to 65°. The day temperature without sun may be 5°, and with sun 15° higher than the respective figures, maintaining a moist genial atmosphere. Vines so small ought not to bear any fruit this year.

**Plants for Peat Soil** (*A. C., Bournemouth*).—The following have been found to thrive well on a peaty sandy soil, but it must be understood that many of them are more vigorous and lasting on a good loamy soil. **Bulbs**.—Crocus in variety, Snowdrops, *Gladolus purpureus*, *G. brenchleyensis*, *G. gandavensis* in variety, Narcissuses, *Bulbous Irises*, *Lilium candidum*, *L. tigrinum*, *L. auratum*, Winter Aconites, *Erythronium Dens-canis* (Dog's-tooth Violet), *Scilla sibirica*, *S. bifolia*, *S. nutans*, *Fritillaria meleagris*, *F. imperialis*, *Funkia Sieboldi*, *F. ovata*, *Tritonia aurea*, *Eucomis punctata*, *Muscari botryoides*, and *M. monstrosum*. **Perennials**.—*Orchis mascula*, *O. Morio*, *O. ustulata*, *Statice Gmelini*, *Tritoma Uvaria*, *Anemone Honorine Jobert*, *A. Pulsatilla*, *A. appennina*, *Spiraea filipendula plena*, *Saxifraga granulata*, *S. granulata plena*, *S. crassifolia*, *S. umbrosa*, *S. paniculata*, *S. aizoides*, *Stachys lanata*, *Mimulus cardinalis*, *Dielytra spectabilis*, *D. eximia*, *Corydalis nobilis*, Foxgloves, *Paeonia tenuifolia*, *Oxalis acetosella*, *O. Bowiei*, *O. atropurpurea*, *Iris foetidissima*, *I. foetidissima variegata*, *Arabis alba*, *A. alba variegata*, *Iberis saxatilis*, *I. corraefolia*, *Campanula carpatia*, *C. carpatia alba*, *C. rotundifolia*, *C. pusilla*, *C. pusilla alba*, *Salvia patens*, *S. fulgens*, *Fuchsia globosa*, *Lathyrus latifolius*, *Lychnis Flos-Jovis*, *Veronica prostrata*, *Thalictrum minus*, *Isopyrum thalictroides*, *Aubrietia purpurea*, *Phlox subulata*, *Acanthus spinosus*, *Symphytum officinale*, *Columbines*, *Cerastium tomentosum*, *C. alpinum*, *Polygonatum multiflorum* (Solomon's Seal), *Gentiana acaulis*, *Gnaphalium arenarium*, *Hepatica triloba rubra*, *H. triloba caerulea*, *Omphalodes verna*, *Sedum spectabile*, *S. Sieboldi*, *Stipa pennata*, *Veratrum nigrum*, *Vinea major*, *V. minor*, and *Primroses* double and single in variety. **Biennials**.—*Lunaria biennis* (Honesty), Canterbury Bells, Wallflowers. **Annuals**.—*Collinsia bicolor*, *Omphalodes linifolia*, *Coreopsis Drummondii*, *C. tinctoria*, Sweet Alyssum, *Nasturtium* (Tom Thumb varieties), *Saponaria calabrica*, *Virginian Stock*, *Helichrysus*, *Silene pendula*, *Clarkia pulchella*, *Brachycome iberidifolia* (Swan River Daisy). All the annuals, with the exception of the *Brachycome* and *Tom Thumb Nasturtiums*, would make a better display and flower longer if sown the last week in August to flower the following year. *Weigela rosea*, a dwarf shrub, we have known to flower abundantly in a bed composed of peat soil in which hardy Azaleas and Rhododendrons were planted.

**Herbaceous Plants for August** (*J. Henshaw*).—Plants that bloom towards the end of August are much more limited than those flowering at midsummer, but the following may generally be depended upon to bloom about the period you desire:—*Anemone japonica* var. *Honorine Jobert*, *Pyrethrum uliginosum*, *Aster Amellus*, *A. hyssopifolia*, *Sedum spectabile* (syn. *fabarium*) *Solidago lanceolata*, *S. altissima*: these may be had in bloom at the time named and through September if they have a favourable position and catch the full sunshine. *Coreopsis lanceolata*—this is usually at its best the end of July if left undisturbed in the border; but if taken up in April and transplanted its blooming period will be retarded for ten days or a fortnight. The *Pyrethrums* and *Asters* above named should not be disturbed at their roots in the spring if wanted to bloom at the end of August. Other plants we have usually found to bloom at this time are *Rudbeckia Newmanii*, *Echinops ruthenicus*, *Lathyrus rotundifolius*, *Fuchsia globosa*, *Statice Gmelini*, *Tradescantia virginica*, *Campanula rotundifolia* (Harebell), *Polygonum Brunonii*, *P. Sieboldii*, *Oenothera macrocarpa*, *Lobelia cardinalis*, *Tritoma Uvaria glauca*—the two last-named should have a little cocoa-nut fibre or ashes placed around the crowns at the commencement of winter for protection. *Tritonia aurea*, *Eucomis punctata*—these two are bulbous. *Veratrum nigrum*, *Liatris squarrosa*, *Physalis Alkekengi*—the last-named is berry-bearing, and has a handsome inflated calyx. One of the finest of herbaceous plants is *Delphinium formosum*, usually in bloom at midsummer, but may be had in bloom the end of August by cutting down the leading shoots about the middle of May; other shoots will spring up, and these will be found of great service in August and September. The herbaceous *Phloxes*, too, must not be overlooked, a great number of varieties being now in commerce, as they are amongst the very finest of plants for the herbaceous border to bloom at the time named. These like a deep rich soil, and are greatly benefited by some well-decayed manure being forked in about their roots in the spring, and after a few years when the stools are too large they should be taken up and divided.

**Name of Conifer** (*Young Gardener*).—*Taxodium sempervirens*.

**Names of Plants** (*Arthur Paine*).—*Physalis Alkekengi*. (*Workshop*).—The *Primula* is a very good one, the flowers being not only large, but of excellent shape. No. 4, *Asplenium viviparum*. The other specimens were not only

insufficient, but were quite withered. (*J. E.*)—1, *Asplenium caudatum*; 2, *Camp-tosorus rhizophyllus*. The Orchid is *Ansellia africana*, the Fern is *Davallia dissecta elegans*, and the other specimen is a leaf of *Dasyllirion acrotrichum*.

**Moulded Combs—Dead Bees** (*Comber*).—We have submitted your query to Mr. Cheshire, who replies thus:—The fact of the pollen being mildewed is not serious. As the bees strengthen and the weather grows warmer they will remove the refuse pollen and clean the combs perfectly. No doubt you left your hive too large. Bees must be confined by a division board or dummy to a number of combs proportionate to their strength, only so many being given them as they are able fairly to cover. The division boards should be either good non-conductors of heat themselves, or they should be protected by having all the space between them and the hive side filled with chaff. This matter we shall be very soon illustrating by woodcuts. The fact of dead bees being found in numbers on the side frame shows an error or omission. It is usual to cut holes through the combs, called winter passages, and by means of these the bees are able to condense as temperature falls, the passages giving an opportunity to those bees of the side seams to pour through the openings as the others retire from them in the act of condensing. These winter passages we have come to regard as an old-fashioned expedient which we now, for a double reason, never use—an advantage, as this hole-boring is a destruction and loss of many cells. First, we use flour cake, and this turned down upon the frames is quickly bored away by the bees as they consume it, leaving passages in the very snug part of the hive, as we now winter them with quilt and chaff box above; and, again, we use hives so thoroughly non-conductive that the bees prefer to cluster, not in the centre of the frames away from the walls, icy cold as they are in too many hives, but against them, and they are always free to pass round the frame end from comb to comb. In this way the bees are warmer than they can ever be made by the inconvenient and retrograde closed frame ends for the introduction of which an effort is now being made.

#### COVENT GARDEN MARKET.—MARCH 9.

TRADE keeps very quiet, supplies being limited, and business the reverse of brisk.

#### POULTRY AND PIGEON CHRONICLE.

#### MANURING AND IMPROVING OF PASTURE AND PARKLANDS.

(Continued from page 181.)

IN the management of grass land we cannot overlook the great variety of soils and climates in which they are found. For instance, we have the poor hill pastures on the chalk, limestone, sand, and gravel formations; on the other hand there are the alluvial soils of Somerset, with the strong loams or clays of Leicestershire and some other counties. In the letting value of these pastures and their intermediates there is a great difference, probably varying from 5s. per acre to as many pounds sterling; it is therefore evident that the manuring and management must vary greatly. Where there is good natural pasture little manure will be required, but it must be remembered that good management is the only way the best of pasture can be made to yield its full benefit and profit to the occupier. On the other hand, the hill

pastures will require judicious outlay for manures and improved modes of feeding by stock. Under any circumstances where the land is thin and poor, manuring and maintaining a full plant of grasses should be attended to; and it is also especially advisable that all manuring should be accompanied by mixtures of earthy substances as composts, excepting on the steep hillsides, where carting of heavy materials would be expensive and often impossible.

The advantage of maintaining a full plant of herbage, even in the best pastures, is frequently made a matter of only secondary importance. The destruction of the finest and best herbage is often caused by the injurious feeding by sheep stock during the winter months, and we speak of this in reference to the best bullock pastures especially; we will therefore quote from Mr. Lawes' paper, illustrating the value of the Clovers in the best pastures of Leicestershire. He states, "In my last letter I mentioned that through the kindness of Mr. Pell, M.P., I had been given the opportunity of investigating the properties of the herbage and soil of a rich Leicestershire pasture, and added that I proposed in a future communication to make some further remarks in illustration of the subject of grass land in general as derived from my examination into the properties of this specially rich pasture. There is a common saying in Leicestershire, 'The more white Clover the more beef,' and it is evident that in the pasture which I have had under examination white Clover occupies a very prominent position. It is probable that an increase of live weight equal to 500 lbs. is produced upon each acre of this land in the six months' grazing; but it is hardly possible to form any accurate measure of the amount of grass which is consumed in the production of this result. It is also evident that to fence off a small portion of the field, and then cutting the produce two or three times in the year, would give a false estimate of the quantity grown, as well as the quality of the grass which enters the animal's stomach day by day. To meet this difficulty the plan was adopted of plucking the produce by hand at intervals of a few days, and by this means we obtained a sample which fairly represented the character of the food. In our various experiments upon fattening oxen we estimated that about 12 to 13 lbs. of dry food was consumed to produce 1 lb. of increase. In the experiments carried on many years ago at Woburn the following quantities of food were consumed to produce 500 lbs. increase in a fattening ox:—1½ ton of Clover hay, 16 cwt. of corn or cake, and 5 tons of Swedes. The sum of these would be about equal in weight to 3½ tons of hay. Now, without going into the question of how far the grass on an acre of the Leicestershire pasture would be equivalent to the food I have named, its consumption at all events brings about the same result so far as the production of 500 lbs. increase of live weight in a fattening animal is concerned, and we get in the comparison some idea of the wonderful qualities of such a pasture as that which I have under examination. If it be an accepted fact that the production of a large accumulation of food of which the two most important elements are nitrogen and potash, and further that a very essential plant in a good pasture is white Clover, the question of producing a good pasture is in a great measure reduced to the means of providing the nitrogen and potash at the lowest cost, and to the treatment of the land in such a way as to encourage the growth of white Clover."

Taking this quotation as a whole it is extremely significant, and highly suggestive in relation to various points in the establishment of a new pasture, as well as the treatment of old grass land. One point seems to stand out in bold relief—that of the value of perennial white Clover, if not the actual necessity of it. The only question arising in our mind is the desirability of considering the kind of soil, for when we know the manures required to produce it in perfection to be nitrogen and potash we can

understand the reason why white Clover succeeds so well upon strong and clay loam soils, and how difficult it is to maintain a plant of it upon light and poor soils; it is therefore clear that in nearly all strong soils potash is a constituent, requiring in consequence but little or none to be added in the manure. In the light poor soils, however, the potash being almost or entirely absent in the composition of the subsoil, it becomes necessary to apply manure composed largely of potash. Mr. Lawes has shown that the white Clover is found to prevail in all the best and most fertile bullock pastures, and this the home farmer should bear in mind. Upon any soil we should endeavour to obtain and maintain this white Clover if we wish to have a good turf and valuable pasturage, and this will be best secured by constant and judicious feeding with cattle, and giving liberal quantities of decorticated cotton cake to the animals whilst grazing. The practical treatment, however, of the droppings of the stock must have direct and constant attention, by either knocking and spreading the dung or collecting it, and mix with earth as a compost for future use; for the manurial value of dung voided by cattle eating decorticated cotton cake is proved to be so strong as to act injuriously on certain spots, unless it is spread or collected until a year or more has elapsed.

Obtaining a plant of white Clover where it is deficient, either in old or recently laid down grass land, is not only a difficulty sometimes, but practically the seed should be sown with permanent grasses if necessary. If, however, the Clover only is deficient, the renovating may be obtained in most soils by frequent manuring. In general it will be necessary to sow about 10 lbs. of seed per acre, and the best time to sow it is during the latter half of July or early in August. Before the seed is sown the land should be thoroughly dragged, so as to produce a loosened surface, and be finished with a heavy roller. Our reason for referring to this matter minutely is because when the seed vegetates it requires protection in its first and second leaves against the depredations of slugs, and we find this is best obtained by the young grass blades which shoot up from the old stocks, and which protect it, and until the following spring the grass should never be fed off by cattle or sheep; it will then be found that the autumn growth of the old grass will act as a protection during the winter months, not only against insect depredations, but also the damage which might accrue from the effects of frost and adverse winter weather. In renovating light poor soils, instead of employing perennial white Clover seed only, we prefer to mix about half the quantity of seed required with *Trifolium minus* or yellow Suckling Clover; this is also a perennial Clover, and will be quickly established on light soils if the same means are used as recommended both in seeding, manuring, &c., as for white Clover, except that instead of depending upon the soil to supply potash it will be necessary to supply with a liberal hand not only potash and nitrogen in the manures, but bone phosphates also.

The after-management of the turf upon light land requires some remark here in contradistinction from the best soils fed by cattle only or chiefly, for in our light soil pastures we are bound almost entirely to feed with sheep. The point of management which then arises is to do this and maintain the plant of grasses of superior sorts whilst making use of the produce for grazing, for although we may feed with sheep eating the best cotton or linseed cake, yet the plant may be destroyed by injudicious feeding. For instance, the sheep should not be allowed to crop the turf too bare, especially in the winter months; and the best way to prevent injury is to avoid promiscuous feeding, and fold off the produce occasionally as the food becomes sufficient, not allowing the sheep to lie back more than one fold. It is evident that there are at least two ways by which either old or new pastures may be seriously injured, the latter especially—namely, the plants of the best grass being starved out for want of manure, or eaten by hungry sheep. In our next and concluding article we may have to quote again from Mr. Lawes' paper upon some important points connected with our subject.

(To be continued.)

#### WORK ON THE HOME FARM.

*Horse Labour.*—Some of the lost time must now be recovered by making all possible speed in working the animal power of the farm, whether horses or oxen. The latter, upon many farms where steam power is not available and the land has become foul, may now be worked with advantage for the remainder of the season, and until after the Wheat seedtime is completed. They may then be put into boxes for winter fattening, for which purpose they will be in forward condition if they have been liberally fed during the working period. They should be fed at the same cost per head per week as the horses; they will then not only be strong in their work but will gain flesh at the same time. We do not, however, recommend ox labour in lieu of steam power, but advise the home farmer to anticipate all the labour

on the land likely to be required; and, in order that the work may be kept well forward, to employ steam for the heaviest work on the fallows for roots during the time that the horses are employed upon the Lent corn seeding. Upon the mixed soils where roots have been fed off by sheep we much prefer to sow the white Canadian Oats, or other early white Oat, instead of Barley, as the latter often proves only a thin grinding sample, whereas the Oats are sure to prove good if sown in good time. It is a matter, too, of considerable consequence whether the land is to be seeded with Clover; for if not, we have often grown capital stubble Turnips after the early Oats, as they are usually fit to cut ten or twelve days before the earliest Wheat. When the Oats are tied and set up in stook our plan is to plough and drill the Turnips between the stooks every evening. A capital crop will generally repay for such a practice.

We have lately referred to the stable management of farm horses, and we consider their health and well-doing is of so much importance that we return to the subject. It is quite usual for farm horses to stand in the stable tethered three or four in a row; but we dislike the plan, for they cannot feed so comfortably as they should do, and are far more liable to accidents. Instead of the old-fashioned rack overhead with manger below—in which the animals are accustomed to feed, the stronger animal getting the chief share of the food—we place the horses in pairs in stalls divided with boarded partitions 10 feet 6 inches in width. The horses being tethered at either corner are not liable to accidents by crossing ties, nor can they interfere with each other at feeding time, as the boxes in which they are fed (being 2 feet by 2 feet) are placed at each corner of the stalls, with the rack or deep manger for hay or straw on the same level and between the two feeding boxes, wherein they can eat in common. Horses placed in pairs in this way should stand in the stable as they work in the field, those which are found to agree best together being paired. It will then be found that the numerous accidents and losses which occur to farm horses may often be traced to promiscuous intercourse in the stables or yards, which it is the especial object of this system of management to avoid.

*Hand Labour.*—All root heaps or stores should be carefully looked over, and any frosted or decaying roots picked out and used before becoming entirely worthless, after which the heaps may be made up again and rethatched or stored for use during the spring or summer. Many of the Swedish Turnips being injured by the frost will not only prove a serious matter for maintaining the condition of both ewes and lambs, whether as stock or feeding for the butcher, and will require to be largely supplemented by purchased food. We find that the early horned ewes and their lambs have made good proof considering the adverse effect of heavy snow and frost. Many of these lambs have been sold in the London markets, and are fetching a satisfactory price. The early-lambing Dorset downs and their lambs are making satisfactory progress, and a large portion of the latter will be fit for sale at Easter. The Hampshire ewes and lambs of the stock flocks have done fairly well, the number of lambs saved being rather over the average. We find that the lambs are now dying in considerable numbers with the white scour, no doubt the effect of the ewes eating Swedes which are in a partially decayed state, which have a tendency to cause the milk to be unwholesome for the young lambs. It is whilst they are young and before they can eat that lambs suffer from this peculiar kind of diarrhoea. Our remedy, which for many years has proved successful, is ten or twelve drops of tincture of opium, commonly called laudanum, in a wineglassful of water given every three or four hours until the diarrhoea is stopped. The dose for lambs three weeks or a month old is a teaspoonful of laudanum in the same quantity of water, and repeated in the same way until either success or death occurs. The water meadows are rather backward this year, but in consequence of the decayed Swedes, where a deficient provision of Mangolds occurs, the feed of the meadows will be invaluable upon the hill stock farms. We hear much complaint of the ewes suffering from what is termed the foot-and-mouth disease, and also the wether and teg flocks. This has been in cases certified by veterinary professors as foot-and-mouth disease, and treated as the same. We have much evidence to offer, the result of our own experience, as well as that of other practical farmers, that there is this difference in the epidemic fever from which the sheep suffer—that we have never known the sheep take it from the cows, nor *vice versa*; in fact, in certain districts we have never been without it in the sheep, accompanied by lameness, during the several years which the cattle of the kingdom have until recently been perfectly free.

#### VARIETIES.

*MANURE FOR POTATOES.*—"As a rule, I find," says Dr. Voelcker, "that potash salts by themselves do not produce a very marked effect. They produce a greater effect when used in conjunction with phosphate of lime and ammonia. I have found good results from 4 cwt. of mineral superphosphate, which will cost about 15s., and 3 cwt. of potash salts—that is, kainit. That would cost 8s. Then 2 cwt. of sulphate of ammonia, taking it at an average price of 18s., would be 36s.; so that it would cost nearly £3. In many instances when I have applied this mixture I have more than doubled the crop—raised the produce from 6 tons to 12 tons. I need not say that that paid

remarkably well. I should mix the manure and apply it as early in spring as possible, as soon as I had got the ground ready—even before winter. Potash is not liable to be washed out of the land, neither is the phosphate of lime. The only risk you run is that in very wet weather some of the ammonia may be washed out. Artificial manure is not a preventive against disease. I recommend it in order to ensure as large a yield as possible, and a manure which supplies all the constituents in the proper proportion. Farmyard manure might be applied or let alone."

— FARMING IN THE NORTH OF ENGLAND.—A correspondent writes to *Newcastle Journal* as follows:—The storm which we have experienced in this district since the 10th January is now telling with most serious effect upon all hill stock. Hand-feeding of stock with hay has been day by day resorted to, till at last the supply of provender is all but exhausted, and relief cannot easily be had. Never has there been greater anxiety in the minds of flockmasters than there is now. Sheep-rot is prevalent all over the low-lying pastures. Serious losses have already befallen the farmers through deaths, and in scores of instances whole flocks have been sent to the butcher to save them from a total loss. March has come in, true to the tradition, like a lion. The outlook is more doleful than we like to report. Turnips are much injured. Upon arable farms work is very far in arrears. No spring Wheat has been sown, nor will there be any now. Clover leas are yet unploughed to a very great extent, and all the land for the Barley crop lies awaiting the plough. When we will get seed time it is difficult to say; the time of the year is now at hand, but the season to sow is lost, especially for Wheat, and what is intended for Beans, like the land for oats and Barley, is yet all to make ready. With two months of arrears of ploughing lying before him, the corn farmer's prospect is not one bit better than the grazier. The position of either is certainly not an enviable one.

— A SIMPLE TEST OF OLEOMARGARINE.—As there is much more of this product sold in England than the public are aware of we publish this test, which we believe to be a good one, from the *American Farmers' Magazine*. Persons familiar with the process of manufacture of oleomargarine are aware that it is subjected to heavy pressure to express all extraneous matter, so consequently, when ready for sale, it presents a perfectly compact homogeneous mass. In order to detect the fictitious take a smooth-bladed knife and cut oleomargarine. It presents where cut a perfectly smooth surface, while genuine butter when cut with a knife does not present such an appearance, for you will find water oozing out and numerous small holes will appear. With this simple guide no one need be deceived as to the article they purchase.

— AYLESBURY DUCKS.—The Aylesbury trade is not conducted in large establishments, but is carried on exclusively by cottagers who, it has been computed, manage to divide between them something like £30,000 a year. All round Aylesbury the cottagers are wont to keep a small number of birds. The eggs produced are sold by the cottagers to the "duckers," who sometimes contract to take their whole season's supply at a fixed price. These "duckers" are for the most part labourers who are sufficiently independent in their circumstances to be able to devote such time as they may have occasion for to this particular business. They are in by no means a large way, six drakes and twenty Ducks constituting on an average the stock with which they commence the season's operations. They begin to collect eggs in October, and give perhaps 3s. 6d. a dozen for all that are laid, though occasionally, Mr. Fowler says, he has known 12s. a dozen offered. They hatch, not under Ducks, but under hens, usually Dorkings or Cochins. These are set in casks, or small hampers, or cheese boxes, and when the young birds are a few days old three or four broods are put together with one hen. Those intended for market, it is curious to observe, are never allowed to go into the water, but are kept very clean and dry on barley straw, and are fed on hard-boiled eggs, rice, and bullock's liver for a fortnight or so, after which they are treated to barleymeal and tallow greaves. They are kept under cover—whenever convenience can be secured for them—in hovels or in cottages, sometimes as many as 2000 or 3000 birds, partitioned off by boards into thirties or forties, preparing for

market under one management. It is, as we have explained, the "duckers" who accumulate stock in this way, and about this time of year they begin dispatching their birds to the London market; and it is said that, as the spring advances, it is not an uncommon thing for a ton weight of ducklings to be dispatched from that neighbourhood in a single night. Now a ton of young Ducks from six to eight weeks old will comprise perhaps 450 birds, or 225 couple, worth, in the best part of the spring, from 15s. to 20s. a couple. This represents, it may be, £150 or £160 a night, all or most of which goes, not into the hands of any large dealer, but, as it has been shown, is distributed among a very considerable number of people, who in no respect but their thrifty care and enterprise are better off than tens of thousands of Irish peasantry, to whom just such an industry might bring comfort and independence.—(*The Globe*.)

## POULTRY AND PIGEONS

### PRACTICAL SCIENTIFIC BREEDING.

(Continued from page 183.)

#### BREEDING THE SEXES SEPARATELY.

THERE is nothing which causes so much want of success amongst young fanciers as ignorance of the fact, that in many varieties of poultry it is necessary to mate-up distinct yards for breeding cockerels and pullets. We cannot but regret that this course should be necessary. It is in our opinion the result of an erroneous method of judging having been adopted in regard to one sex or the other. Either through a want of practical knowledge of the breeding of the varieties upon which they had to adjudicate, or through caprice, the judges adopted standards for the two sexes which were inconsistent with each other. That is to say, a pair of birds to which prizes were awarded as being of the same variety, were really so distinct that if mated together they would have produced chickens unfit for mating with either parent. The birds shown as a cock and hen of some particular variety were really of distinct varieties, and except in the show pen had nothing in common. Fanciers were more in the hands of the judges than they are now, and instead of resisting this false method of judging, they fell in with the views of the judges and set up separate breeding yards for each sex.

The standard having been thus wrongly fixed, has in regard to some breeds become so universally recognised that it would be quite useless to make any attempt to alter it now. In regard to these the breeder must therefore be prepared to submit to the inevitable, and in addition to his exhibition stock must purchase other birds which are worthless for exhibition, but which are suitable for mating with the exhibition stock of each sex. Two separate strains must, in fact, be formed. This, of course, necessitates the maintenance of a double number of breeding yards and the rearing of a larger number of chickens each year. It also necessitates the possession of a knowledge which is not always easily accessible—namely, the knowledge of the points which are the complement in one sex of the exhibition points in the other. All these considerations render it advisable that a beginner should, before taking up any variety, ascertain that it is not a variety which requires the two sexes to be separately bred, or if this be the case should master the method of breeding each sex.

We may say that there is hardly any variety as to which we have not heard of successful attempts being made to breed exhibition stock of both sexes from the same yards. Permanent success, however, can hardly be obtained in some sorts without breeding the sexes separately, and as to these it is mere waste of time and trouble to make the attempt.

There are, however, some varieties which have only for a comparatively short time been judged by an erroneous standard, and in which a struggle has been going on between the breeders and the judges. In Dark Brahmas, for example, the tendency of the judges was for several years in favour of excluding mottled-breasted birds from the prize list. It was found that the production of well-pencilled pullets and black-breasted cockerels from the same parents was almost impossible. The clearer the pencilling of a hen the more likely were the cockerels bred from her to be more or less mottled on the breast. The leading exhibitors persisted in exhibiting mottled birds. The Crystal Palace Show established a separate class for them. The matter was taken up in the poultry press, and in one way and another it has

now become recognised that a mottled breast is perfectly allowable in a Dark Brahma cockerel. In fact, at the last Crystal Palace Show the separate class for these birds was deemed no longer necessary, and nearly all the prizes were awarded to cockerels more or less mottled.

Many exhibitors of Brahmas had, in consequence of the tendency shown by the judges to exclude mottled-breasted birds, established separate strains for cockerel and pullet breeding, and some of these will doubtless be kept up, but it is no longer necessary to breed the sexes separately. In the case of varieties both sexes of which can be successfully bred from the same parents, it is clearly to the advantage of the breeder to adopt this method. It increases the intrinsic value of the birds individually and as a strain; it tends to preserve uniformity of type, and it does much to prevent those disappointments which so frequently dishearten young fanciers. We do not mean to advise that a yard should never be mated up specially for the production of one sex, but we do mean that this should not be carried to the extent of forming a separate strain.

We think that exhibitors should make every effort in their power to prevent the establishment of such a standard in any variety (the standard of which is not yet clearly settled), that it may be necessary to establish separate strains for each sex; and we also think that the judges should yield in all such points to the known wishes of the leading breeders of each variety.

There is a feeling abroad that it is the business of the judges to fix the points of each breed, and that exhibitors should humbly yield to their fiat, and do their best to produce the article required. With this view we cannot agree. Those who have had practical experience in the breeding of a variety are best qualified to settle the points of that variety. They and they alone can tell which points are most difficult to attain, and can estimate each point at its true value. In these days of all-round judging it is impossible that a judge can have bred all the varieties he has to adjudicate upon; how, then, can he be qualified to frame a standard of points? It is true that in one sense the judges do frame the standard, and we have heard it urged as an objection to the proposal that a formal standard of each breed should be drawn up, that the judges would refuse to follow it. Of course the value of any standard would depend upon its correctness, and it could only be deemed correct or incorrect so far as it represented or failed to represent the ideas of the leading exhibitors. If a standard were correct in this sense the judge who refused to follow it would clearly be in the wrong, and might easily be made aware of the fact. The system which has found favour of late years of having certain classes judged at the principal shows by actual breeders of high standing has done much to bring about unanimity between fanciers and judges. The drawing-up of an authoritative standard of each variety by the leading fanciers of that variety with the aid, if obtainable, of such of the judges as were or had been breeders of it, would, we think, be a further step in the right direction.

Although much is in the power of the judges, we think exhibitors are fairly entitled to have their views respected, and by abstaining from exhibiting under a judge who persistently ignores these views they can do much to prevent the formation of an erroneous standard. They can also, by giving public expression to their individual ideas and ascertaining how far these are in accord with the ideas of their brother fanciers, aid the formation of correct notions by such of the judges as have not had practical experience of the variety.

We cannot pretend to state positively as to which breeds or varieties it is absolutely necessary to breed the sexes separately. We shall be very pleased to hear from our readers as to their experiences in this respect.

(To be continued.)

### PROFITABLE POULTRY IN AMERICA.

LAST year I made a clear profit of almost 1000 dols. on a breeding stock of some two hundred chickens, Ducks, and Turkeys. I do not publish this to boast over my success, but to show others what a woman can do under the most favourable circumstances. These in my case were a splendid stock of breeding fowls, a healthy location, a thorough knowledge of my business in all its branches, and nearness to a first-class market.

Of course some doubting individuals stand ready to declare that it is impossible to make five dollars profit on every adult fowl kept; but if they will stop and consider that I get spring chickens into market during the months of April and May, when they sell readily for one dollar each; that I sell ten and twelve pound capons for thirty cents a pound; that I manage to have

eggs to sell in winter when I can get from thirty to thirty-five cents a dozen; and that I sell a few trios of exhibition birds every year, they will see where the big profit comes in.

Now don't stop right here and give up all thoughts of raising chickens just because you cannot get such prices in your locality, but wait until I give you a few hints from my experience.

I have kept poultry in the west where eggs sold at the "stores" for eight cents a dozen in summer, and poultry sold in the fall for seven cents a pound, live weight, but I made it pay. We lived on a line of railroad two hundred miles from a city market, but I soon found out that all the poultry and eggs from our place went to the city, and I could not for the life of me see why I could not ship such things just as well as the merchant, so I sent a thirty-dozen package of fresh eggs to a commission house in the city; they sold readily and there was call for more. "These small packages of eggs, every one warranted fresh, are just what we want," wrote the commission man. I did some more thinking, and then put on my good clothes and went to the city. Once there, it did not take me long to find a grocer who wanted thirty dozen of fresh eggs every week, so I shipped the eggs direct to him, and saved the commission man's profits. In the fall I sold my poultry the same way.

There was no thoroughbred poultry in the vicinity except that in my yards, and when people began to find out that my chickens were superior to the common mongrel fowls they bought a great many eggs for hatching. There was not one pair of any of the improved varieties of Ducks in the county. I sent a thousand miles for a pair of Pekins, and within a month after they arrived everybody had the Duck fever, and I was overrun with orders for Ducks before a single egg hatched. I also procured some Bronze Turkeys, and sold every egg that I could spare and every Turkey that I raised at good prices.

Every woman who goes into poultry-raising may not be able to get in these "extras," but every woman who desires to earn money by raising poultry and goes into the business with a determination to succeed will be sure to make it pay, even if she sells every egg and every chicken at market prices.—FANNY FIELD (in *Prairie Farmer*).

### TURKEYS AS HATCHERS.

WE translate the following interesting account of the method adopted in France of inducing Turkeys to hatch from M. Voittellier's work on incubation:—

In some places they have endeavoured to replace the natural incubation of hens by forced incubation of Turkey hens; but this mode of hatching has not become general because it has not given, as a rule, more than moderate results.

In order to make the Turkey hens hatch at times when Nature does not call upon them to do so, and when they have not laid (many of those which are subjected to this system after several years become sterile), the most simple means are employed. About the 15th of November a Turkey hen, which has up to that time been allowed the run of the poultry yard, and which has received no previous preparation for the rôle which she is intended to fill, is selected. She is then placed in a box or basket covered by a lid; a nest of straw is formed in the box or basket of such a height that the lid when closed on the back of the bird prevents her from standing upright; the lid is firmly fastened or loaded with large stones.

Every morning the birds are allowed a quarter of an hour's liberty for feeding, after which they are replaced in their narrow prisons. When several days have expired they begin to accustom themselves to their new rôle, and most of the birds set in the same place return by the force of habit to their respective nests after feeding without making any mistake. Some old eggshells filled with plaster are then placed under them by way of trial. They take little by little to the ways of hatching, and end by deciding to sit steadily. The lid of the box or basket is then left open; they receive twenty eggs and sometimes more according to their size and aptitude for sitting. All these preparations require from eight to eleven days. Some birds, however, obstinately refuse this forced maternity; these should be immediately sent to the fattening pen as being unsuitable to be bred from.

It is worthy of remark that the progeny of a Turkey hen, which is a good sitter and good mother, always resemble their parent in this respect. In some places Turkeys absolutely refuse, it is said, to be forced to hatch, but these cannot have been bred sufficiently with a view to the end which they are desired to attain.

Many henwives have a superstition that the time of hatching should be so arranged that the birds should hatch out in the last quarter of the moon. Our own observations on these points,

applied as well to natural as to artificial incubation, do not altogether negative this traditional idea. We avow at the same time that, without absolutely arriving at any rule upon the subject, the results obtained under these conditions have presented a certain advantage.

The Turkey hens which have ended by hatching can hatch out without any interval four or five clutches. They have been sometimes known to hatch as many as eight. As each batch is hatched out one mother takes charge of all the chickens, and the others continue to act as hatching machines.

In spite of its simplicity this system of winter incubation presents much inconvenience and gives much cause for anxiety. The eggs are broken by such of the hens as are too heavy or awkward, and the chickens are frequently crushed just before hatching out. The nests are fouled, and an evil which is without any certain remedy—the hatchers are covered with insects, with which they affect their chickens. The persons who carry on this mode of hatching reckon that from about four hundred eggs they will obtain a hundred chickens. Even admitting that the clear eggs can be removed (which is very difficult in consequence of the birds fouling their nests to such an extent that it is impossible to see through the eggs) and that the eggs are not broken, ten Turkeys at least must be employed to obtain this meagre result. Then how many anxieties are entailed by this abnormal method of hatching! It is necessary to take off the Turkey hens and clean the nests each morning, a work which cannot but be repugnant to the henwife; then what a quantity of food has to be given to the birds! All this is a mere nothing, however, compared to what may happen if an epidemic should reach the yard; then fifty or a hundred hatchers die in a few days, and there is nothing but ruin for a poultry yard in which the hatching is so managed.

#### TOY PIGEONS—AFRICAN OWLS.

THERE is no race of Pigeons which more truly merits the appellation of "Toy" than these little beauties of the sunny South. In our descriptions of nearly all the varieties of Toy Pigeons we have begun with due deference to the fanciers of the past by quoting descriptions of each breed from the older Pigeon books. In the present case we cannot do so, for the good reason that these diminutive Owls were unknown to English fanciers half a century ago. We owe their importation to the rapidity of transport in these days, as we owe the multitude of Parrots and other foreign birds imported by Mr. Cross and others, and which can now be purchased for a tithe of the price which our grandfathers gave for such exotics. The general characteristics of the African Owl are the same as those of the old English breed of Owls, save that its size is only about half that of the latter.

We believe that the first specimens of the variety ever seen in England were imported by Mr. Vernon Harcourt of Newnham some twenty years ago; they were white and very small. About eight years ago we saw a number of their descendants which had sadly degenerated in head properties and increased in size, from the stock being allowed to breed in a haphazard fashion. Their home is the northern shores of Africa, Algiers, and Tunis. We have also seen some imported from the Levant. In form they should be short in body with head well thrown back, very short in face and beak, very down-faced, and very round in head, their breast full round and full. Their colours when exhibited should be pure white, blue, or black. Some of the prettiest and most costly when perfectly marked are white with tail of some colour, as black or blue. In Africa they are bred more for form than feather. Their breeders, we believe, refuse to pick out those of any special marking, and consequently the great importers are obliged to take large and miscellaneous flights. We have seen beautiful collections freshly arrived at Mr. Baily's establishment in Mount Street, but the larger proportion of them, though capital in head properties, were not in feather such as to suit fanciers of feather; hence the high prices of the very few selected from them as match pairs. A young fancier who has a good chance can hardly do better than pick up at moderate prices some of the mismarked birds. We once purchased a tiny blue cock, exquisite in form, but with white cheeks and some white in flights; his produce were very good, probably as good as from a perfect bird at five guineas. To those, too, not entirely devoted to the exhibition mania there is a charm in looking for variety in the produce of our birds.

African Owls are said to be delicate, and we believe that there are well-known instances of large and expensive flights being carried off by exposure to east winds. We can only say that the above-mentioned little cock reached us in the month of November, and insisted upon roosting and nesting through the winter in an open cart shed, apparently to the great advantage of his health. Among

collections of African Owls peak-headed birds are occasionally seen, and these when white are sold as White Turbits. Of course foreign Owls from the fineness of their heads have been much used to improve English Owls. We do not approve of crossing the two kinds, and look with suspicion on very small specimens shown as of the English type, believing them to have an admixture of foreign blood. African Owls are bright and lively little things, and in a good situation may have complete liberty.—C.

VERMIN ON FOWLS.—It seems strange to me to see in the "Country Gentleman," every now and then, inquiries as to what will kill lice on fowls. Let me give you my experience with fowls; then you will see why these inquiries seem strange to me. Just about five years ago I purchased some show Bantams. When the spring of the year came I soon had chickens; it was not long before one or more began to be dumpish, would continually gape, and finally die. I could not account for it for some time, but one day, just after a pretty Silver chick died, I held it in my hand, and on thoughtlessly rubbing up the feathers a little I saw something on its head, and quickly discovered it to be a patch of lice boring into its head, which seemed to me quite enough to cause its death. Then I found some under its neck. I had seen in the "Country Gentleman" a statement that kerosene mixed with lard enough to prevent its running would kill lice on fowls. I tried it, and it thoroughly killed them. I now go over every brood of chicks when they are ten or twelve days old, and rub the kerosene and lard on their head and under their wings, and wherever else I find lice. They look very rough for some hours afterwards, but it is not long before they look all right again. From the time I began to do this I have had no chickens gaping and dying. I lose chickens from time to time, and fowls, but not on account of lice.—J. J. (in *Albany Country Gentleman*).

#### OUR LETTER BOX.

**Egg Tester (N. S. R.).**—You will find full particulars in "Our Letter Box" on page 144, No. 34.

**Spice for Chickens (Idem).**—There are many sorts in the market. We never recommend any particular manufacturer. We do not use any. As a stimulant we advise bread and ale given once or twice a day. If the food given be varied and chosen with due regard to its heat-giving and flesh-forming properties, stimulants should only be necessary in exceptional cases.

**Curing Egg-eating Hens (C. W.).**—Hens generally eat their eggs from want of lime or the material necessary for forming the shell. They eat it first for the sake of the shell, in order to form that which is in course of being produced. Nothing is so good as to throw some baskets of bricklayers' rubbish about in their haunts. It is from want of this that hens in their laying season eat the mortar from between the bricks. When they eat the shell they learn to like the yolk, and then take to the egg. There is no real cure, but if they are watched when they lay, and driven from the nest after the operation is complete, they sometimes give up the habit. Another less troublesome plan is to obtain some very hard artificial nest eggs and put them in the nests, and to lay them about their haunts. They peck at them, and finding it fruitless give up the habit.

#### REMARKS.

- 27th.—Slight snow showers in morning; bright sunshine in middle of day; starlight evening.  
 28th.—Calm, cold; fine with some sunshine.  
 1st.—Fine, cold; bright sunshine all day.  
 2nd.—Fine, bright sunshine in morning; afternoon and evening hazy.  
 3rd.—Cloudy and dull; high wind latter part of the day.  
 4th.—Damp and misty, with rain greater part of the day.  
 5th.—Mild rain in early morning; fair with some sunshine during the day; heavy rain in evening.

Temperature on the whole rather above the previous week, but still below the average. Rainfall much above it, the fall on the last two days being very heavy.

### GROWING MELONS IN COLD FRAMES.

**I**N treating of Melon culture in cold frames or cool houses I do not wish to disparage hot-water-heated structures and pits or frames warmed by fermenting materials, for I grow Melons in them every season. By such means fruit is obtained at earlier and later periods, and with greater certainty in summer; but there is no reason why Melons should not be satisfactorily grown in cold frames. This I have proved for ten consecutive years, and though the crop was not equally good each year, there has not been what could be termed a failure. The fruits were sent in to table with those grown in artificial heat, and, what is of more consequence, the varieties were the same; indeed, they were the choicest named varieties, and a great number of seedlings, not one inferior to any in commerce. All depends on the treatment; therefore any variety will succeed under this mode of culture, a good Melon being as easy to grow as a bad one.

The seed is sown at the beginning of April in turfy loam rubbed fine, three parts filling the pots, and pressing the soil down gently. The seed is covered half an inch deep, and the pots placed in a hotbed in which Cucumbers or Melons are growing. When the seedlings appear the pots are raised on inverted pots so as to have them near the glass, for it is important that the young plants be kept sturdy. When the seed leaves are formed pot-off singly in 3-inch pots and return to the hotbed, shading from bright sun until established. Water must be carefully afforded to keep the soil moist. The temperature of the hotbed must be 60° to 65° at night, and 70° to 85° by day, according as sun heat may affect the day temperature. Two things are important—the plants must not be given bottom heat, and they must be kept near the glass. Pinch the point out of each plant at the second rough leaf if intended for frames, but if intended for trelliswork allow them to grow, securing the growths to a small stick, and rub off the laterals as they show until stems are secured that will reach from the soil to the trellis. Shift the plants when the pots are filled with roots into 5-inch pots, render the soil firm, and return to the hotbed. The plants must not be allowed to root into the bed, but should be placed on slates or inverted pots to prevent this. Two or more shoots will result from the stopping, and should be reduced to four if more than that number; and if but two shoots start stop those at the second leaf, and when the new breaks are produced reduce them to four, as that number will be required—*i.e.*, two for training to the front, and two to the back of the frame.

By the middle of May the plants will be strong and the

frames at liberty, having probably been occupied with bedding plants, winter Lettuces, forced Potatoes, or Violets. The pits must face south, be well exposed to light, and have shelter from the north. Their depth from the glass to the soil may be from 12 to 15 inches. Ours are lean-to pits, and frames both lean-to and span about 4 feet wide, used for Lettuces and Violets through the winter. If the depth be more, material should be placed in to bring the surface of the soil up to the required height, about 10 inches depth of soil being necessary, and that need only be ordinary garden soil, preferably rather strong. The soil is scooped out in the centre of the frames lengthwise to the depth of a foot in the middle, forming a concavity, and this is filled with any short littery dung and leaves in a partially reduced state that may be at hand. It is trodden down and covered with about 6 inches depth of soil, which is also rendered firm. The lights are placed on and kept closed for three days or a week. In that time the sun will have warmed the soil, and the plants may be placed out one in the centre of each light, the soil being well firmed about the balls, giving a good supply of water at a temperature of 90°, and extending a foot from the plant all around. Water them very carefully afterwards for some time.

In after management it is necessary to afford a protection of mats or other covering at night up to the middle of June, putting them on about 5.30 p.m., and withdrawing them about 7 a.m. unless there is frost, when they may be allowed to remain an hour later. Commence ventilating from 75°, and allow the temperature to range from 80° to 85°, and close at 75° to 80°, but not so early as to cause a rise above 90°. At closing time a sprinkling of water at 90° over the surface of the bed from a rose watering pot will be an advantage, being careful to keep it from the collar of the plants, and to employ it only on bright afternoons. Attention must be given in training the shoots, taking two to the back and the same number to the front at regular distances, securing them with pegs if necessary, but only for a time, as the pegs cause water to lodge, and this induces decay of the stems. Rub off all laterals to within 6 inches of the stem, and remove every alternate lateral on the shoots. This is necessary to prevent overcrowding. Stop the shoots 9 inches from the sides of the frame or pit. The laterals will show flowers at the second or third joint or both, and when these are beginning to open the sprinklings must be discontinued, leaving the lights open about half an inch constantly at night, ventilating freely in the daytime when circumstances admit. Fertilise the pistillate flowers on a fine day, taking care to apply the pollen to the stigmas. Continue this treatment daily until the requisite number of fruit is set, which should not be more than four to each plant; and if the frames are only 4 feet wide, two are sufficient to insure fine fruits. When the fruits are swelling freely a good watering should be given at 90°, and every week for the following six weeks, regulating the supply by the weather, for, if very hot, water will be required twice a week. Damp overhead every fine afternoon at closing time. Ventilate at 75°, keeping the day temperature between that and 85°, and close sufficiently early to secure an advance to 85° or 90°. When indications of ripening are observed, which may be expected in fifty to sixty days from impregnating the flowers, cease watering, omit the sprinklings, and ventilate a little above 70° so as to dispel moisture early in the day, allowing the temperature to rise to 85° or 90°, and if the weather be

damp ventilate slightly constantly. When the fruit is separating from the footstalk, as it will as soon as it ceases to derive support from the plant, cut it with a portion of stem, and place in a dry airy room for a few days until it acquires an even ripeness, when it will be in suitable condition for table. Some experience is necessary to discern exactly when Melons are at their best. Over-ripe Melons as compared with those even under-ripe are very poor. A good Melon should hold its flesh well and yet be as melting as a Pear.

Other matters of detail requiring attention are stopping the shoots one joint beyond the fruit at the time of impregnation, and to keep subsequent growths stopped to one joint. The plants should be examined at least once a week for this purpose, thinning the growth when it becomes so crowded as to interfere with the principal foliage, which should have full exposure to light and air, the laterals being cut back or removed altogether so as to admit light to the principal growths; but do not make great reductions of foliage at a time, cutting back or removing a few laterals at a time and frequently, so as not to give the plant a check. The fruit must have a slate or piece of glass placed under it to keep it from the soil.

A sowing may be made a fortnight later than the first, which will afford plants for putting out early in June, and will produce successional fruit to the first batch.—G. ABBEY.

### TEA ROSES.

I HAVE received a letter from one of the Hon. Secretaries to the National Rose Society requesting me to correct a statement which I made in my last letter on Tea Roses. Mr. Mawley appears to think that I was referring to the number of Tea Roses required to be exhibited by amateurs. Although I was not doing so I cannot refuse his request, as many other readers of the Journal may have been misled. I cannot do better than quote Mr. Mawley's words. "In your letter to the *Journal of Horticulture* on Tea Roses you appear to be under the impression that Mr. Prince has offered in the amateurs' classes prizes for twenty-four and eighteen Teas respectively. This, however, is not the case, as the enclosed schedule will make clear. It is true that it was at Mr. Prince's suggestion that the number of Teas to be shown by nurserymen was decided upon for the present year to be twenty-four and eighteen. Hybrid Teas were excluded from all the Tea classes last year, and will be again excluded this year. The box of fine Teas was last year disqualified for having a bloom of Cheshunt Hybrid in it."

My remarks were directed to the large number of Teas and Noisettes required of both amateurs and nurserymen, but especially with regard to the latter. Mr. Robert Baker also writes correcting a statement I made as to his not being upon the Sub-committee. I do not know how I can have been misled on this matter, as I was Chairman of the meeting at which the members of the Sub-committee were decided upon, and I distinctly remember the discussion upon the uselessness of nominating men, however valuable, who lived at a great distance from London. However, I am delighted that Mr. Baker is on the Sub-committee, as no one is better qualified than himself.—WYLD SAVAGE.

"WYLD SAVAGE" may be right when, on page 187, he says that twelve should be the maximum number of distinct Teas or Noisettes for which prizes should be given. This is a question upon which opinions differ; but I feel sure that seven out of every ten growers of *Rosa indica odorata* would say with "WYLD SAVAGE" that to get a perfect stand of these Roses, such as would be considered "one of the most lovely sights of a Rose show," twelve trusses must be the limit. But when "WYLD SAVAGE" begins to enumerate the very few Teas and Noisettes which alone he considers fit for such a stand, he alarms me. He abstains from even mentioning names which must bring happy memories and pleasurable sensations. A Lenten penance it must be; or where are Anna Olivier, Comtesse de Nadaillac, Innocente Pirola, Jean Ducher, Madame Willermoz, Perle des Jardins, Rubens, and Marie Van Houtte? Yet all the above are grown for sale by Mr. B. R. Cant as fit for exhibition. And as for Noisettes, may I not add Caroline Kuster?

The last three cruel winters have done much to discourage growers of Tea Roses, and such communications to the Journal as this one from "WYLD SAVAGE" will not improve matters. I should like to see a hundred Teas grown where one is now grown. I should like also to see these lovely Roses shown at the two National Shows in trebles and in masses. As "WYLD SAVAGE" says, the blooms must be most perfect if your stand of twelve is

to come up to a high level of excellence; but in my humble opinion stands of these Roses, as I have seen them at some shows where prizes are offered for the best collection of Tea Roses, are infinitely more lovely than twelve distinct single trusses. Probably Mr. George Prince in choosing twenty-four and eighteen as the number of varieties to be shown has for his object the encouragement of this branch of Rose culture. All amateurs to show eighteen distinct must increase their stock, and some of them the number of their varieties. This will be a good result of Mr. Prince's stipulation. However, I am not going to say that "WYLD SAVAGE" has made a mistake in publicly doubting the expediency of giving prizes for twenty-four distinct Teas, for he is and has been for years a connoisseur in those Roses, and I am one of his young unknown pupils; but I do think that his protest led him to forget the existence of six or eight of the most lovely of his favourite Rose family.

Reverting once more to Tea Roses and exhibitions, how one longs to see stands of trebles, yes, and double trebles, which will include in the half open and bud state Safrano, Madame Falcot, Homère, Céline Forestier, David Pradel, &c.—varieties which the exhibitor proper either does not grow or reserves for his button-hole.—J. A. W.

[Another interesting letter on this subject will appear next week.—ED.]

### THE VEGETABLE AND FRUIT QUESTION.

#### A REPLY TO CRITICS.

I AM truly glad that I happened to start a subject which evidently interests many, and which having led to, I hope, a useful discussion, will lead as a result to profitable action. There have been on the whole up to this time (March 4th) eight articles long and short written and printed since I last wrote, hence it seems now time for me to venture on a reply. I have joined fruit to vegetables in the heading of this paper, because they are combined in my thoughts, and one as much as the other wants investigating, and the supply of both I believe to be inadequate to the needs of the people. An increase of the supply would also, I believe, lead to much profit if the suppliers have energy and discretion. Also the Editor has done me the honour to transcribe to these pages a letter of mine in my county paper, entitled (and I chose, I hope, a catching title), "Plant Apple Trees." I beg to thank Dr. Hogg very much for thus giving a national circulation to what before had only a local one. I want to do good afar off as well as near home.

Now the letters that have appeared from other pens than my own have been naturally of two kinds—letters of approval and the opposite. One general remark: In this almost universal agricultural depression I find it so difficult to get men out of their life-long and set groove, and to get them to grasp a new and probably more profitable undertaking. I fear this sluggish nature which almost prefers quietly starving down to entering upon a new and fresh career is inherited by Englishmen from their Saxon ancestors, those "heavy men in country bred," who loved to eat and sleep, but lacked the adaptiveness of the Norman's nature.

My views have, as I said, been approved and disapproved, the former by the buyers, the latter pretty generally by the sellers. For the benefit of these latter I will tell the following tale: In a certain town the tradesmen in one special line of business, and that one embracing principally the necessities of life, were always complaining that there were too many of them; that trade was slack, nay, insufficient for all to do even comfortably well. Many were worthy men; most were a little bit drowsy, whistled often for want of thought, not seldom had their hands in their pockets—not, they would have said, to turn their money over, but to be easy and comfortable. They did not agree with each other very well, because each wished one or two others would be off somewhere else. But if they disagreed in some points they all agreed in this—that there were too many of them. When lo! another of the same trade came into the town and opened a taking-looking well-stocked shop. "Whew! poor fellow, he will soon be bankrupt, there's no room for him; why we can only just live." This they all said, alone, and to each other. But the new comer did not intend to become bankrupt if energy and skill and civility and cheapness could keep him out of that very disagreeable Court. The old stagers were also roused, and they wished to avoid a smash. A new spirit was infused in all, notice was drawn to the town, and custom came in instead of flowing to the city some miles distant. The fresh man whom nothing could daunt made a fortune, and the others, save an unsteady one, did better than before. Not only do storms clear the air but energy begets energy, and the most energetic man will in trade do the best.

Next I may as well state what is evident, that the market gardeners fear the rivalry of the farmers; their views are strictly commercial, like the tradesmen in the above tale. Theirs is not, considering what man's nature is, a view to surprise us; but that they will succeed in keeping other men from planting vegetables and fruits on a much larger scale is not what I believe; nay, the more strongly they say "don't" the more readily will others say "do." The most energetic will win the race, whatever he be called, or whatever his trade has been.

"A. M. B." speaks approvingly of a larger planting of fruit trees, saying, and rightly, "In fields, pleasure grounds, and even parks Apple trees are as ornamental as Thorn trees; Walnut trees are stately, while Plum and Cherry trees might line our roads, as they do so many of the highways in Germany and other continental States." "A. M. B." also gives good advice as to vegetables; indeed his or her letter is marked by so much wisdom that I would ask readers to turn back to it and re-read it, they will find it on page 126. Again, "F. R., West End," makes a point when he or she says, "If the quantity of vegetables grown is as great as your correspondents expect, how do they account for the almost prohibitory price?" Certainly I hear of vegetables being dear at the same time that they are represented as unsaleable. Mr. Peter Ferguson says plainly, "Most of the Rector's critics have only looked at the matter from a mercantile point of view." The trade view is one way, the housekeeping view is another, this especially as regards vegetables; but as to fruit, all or nearly all agree that there is no superabundance, which implies that there is a living to be made by planting them on an extensive scale hitherto unknown.

There is another point I would notice in the need of teaching the poor to cook. I have always, and have had regularly for years, one servant who is very young, and I train him for good service, with on the whole much success; but the daintiness of such boys, and I believe girls too, is great, and owing to the few meats and drinks to which they have been accustomed. There should be schools of cookery in towns and larger villages, or in one of a group of villages. Popular short papers on good and useful cooking of vegetables, and dishes in which vegetables should bear a part, would be very good things. Cannot any or several lady readers do something for us in this way? To benefit and do good to the poor is an hereditary part, and a blessed part, of an English lady's life and work.—WILTSHIRE RECTOR.

P.S.—To show how the subject of getting more out of land is moving in men's minds. On taking up the January number of "Chambers's Journal," I read in a paper entitled "Experiments in Workhouse Management," "Probably in some instances farming and gardening will be made to play a much greater part than they do now in workhouses, it being calculated that a quarter of an acre of land to every inmate of over ten years of age would make a workhouse absolutely self-supporting. The country workhouses have abundant opportunities of trying that experiment, though of course they will have to meet the usual objections to the utilisation of pauper labour." Everywhere men are seeking to make the land yield more, and from this desire will, I believe, arise a great and grand future position for gardeners and gardening.—W. R.

#### BRIEF NOTES FROM CHISWICK.

AT all seasons the visitor to the Royal Horticultural Society's Gardens, Chiswick, may, however brief his stay, find something worth remembering and recording. So in a recent call of very short duration I observed several plants in flower, respecting which the following notes may be of interest. Turning first to the rockery, though not the best time of year to visit it, there were several charming little plants in flower, especially notable being the

*Crocuses*.—The utility and beauty of these plants for planting in the nooks of a rockery are well exemplified by a number dotted about in small clumps. They are now flowering freely, and render it quite bright in association with several other plants. The forms grown, were, I believe, received from Mr. Maw, the following being those represented—*Crocus Imperati*, bright purple, 6 inches high; *C. lagenæflorus* var. *sulphureus*, rich sulphur yellow with brownish streaks; *C. aureus*, fine golden yellow; and *C. reticulatus auritestus*, very dwarf and neat, with bright yellow flowers.

*Snowdrops*.—A collection of varieties of *Galanthus nivalis* included several forms with unusually large flowers, neat in outline and of great substance. The most remarkable was, however, *G. nivalis* var. *Melvillei*, which bears the name of the gentleman from whom the collection was received. It was rather taller than the majority of the others, with large nodding flowers, pure white, and with broad rounded petals.

*Hepaticas*.—Clumps of the charming blue *Hepatica triloba*

single and double were most attractive, and certainly at this time of year there is nothing to surpass them out of doors. The clearness and brilliancy of the tint affords a most agreeable contrast with the *Crocuses* already mentioned. Near them plants of *Cyclamen ibericum* and *C. Coum*, with the elegant pale blue *Chionodoxa Lucilæ* also attracted attention.

*Epacris*.—In the houses *Epacris* were in very good condition, many excellent varieties being grown; but the two which especially pleased me were *E. elegans* and *E. miniata splendens*, two plants side by side showing their distinctive characters admirably. The former is rarely seen, but it well deserves attention, for though the flowers are small individually they are freely produced towards the points of the shoots, their neat campanulate form and pure white colour rendering the plant most useful for cutting. I do not know when or by whom the species was sent out, but it was included in Messrs. Rollisson's collection several years ago. The other, *E. miniata splendens*, is a well-known and

Fig. 47.—*Epacris miniata splendens*.

Fig. 48.—*Epacris elegans*.

remarkably handsome variety, greatly surpassing the species in the size and colour of the flowers. The tube is a brilliant vermilion or scarlet, the small lobes being pure white—a striking contrast. It is very floriferous, but of rather peculiar straggling growth, though with a little care it may be kept in satisfactory condition. The woodcut represents a flowering shoot of each of these *Epacris*, and well shows the form and size of the flowers.

*Sarcochilus Hartmanii*.—To conclude these jottings I may notice two rather singular Orchids which were flowering in one of the warmer houses. A specimen of *Sarcochilus Hartmanii* had about eight spikes each 6 inches high, bearing small flowers with oval white petals and sepals, the lip being diminutive and marked with reddish lines, something in the way of the peculiar *Vanda Cathcartii*. Though not a showy Orchid it is certainly pretty and is very rarely seen. It is quite distinct from any other form in the genus that is known to me.

*Dendrobium Kingianum*.—Though not to be compared with many species of *Dendrobium* in point of beauty, this is yet possessed of some attractions. The flowers are small, about half an inch in diameter, rosy purple, with obtuse ovate sepals, narrow petals, and a small light-coloured lip streaked with reddish purple. They are borne in short few-flowered racemes, which arise from the top of the growth, usually attended by two or four dark

green leaves. It was figured in the "Botanical Register" in 1845, and is there stated to have been obtained by Messrs. Lodiges at the sale of Mr. Bidwill's New Holland plants a few years previously. It has also been known under the generic name *Desmotrichum*.—L. CASTLE.

#### EFFECTS OF THE PAST WINTER ON VEGETABLES.

I HAVE been examining our vegetables, and I must say the sight is not very encouraging. I find to my dismay that we are in a worse state now than we were at this time last year. Last winter Brussels Sprouts were very little damaged; we had a plentiful supply till far on in the spring, at the present time they are nearly all decayed. Ours were planted the first week in April, and were then fine healthy plants. Later plants were dead long ago, which proves that early plantings are the best. Last spring we had plenty of Broccoli that stood the severe weather; this season there are very few. About a fortnight ago I thought that we had come through the severe weather very well, as they then looked fresh; since then the return of bad weather has killed most of them. The Purple Sprouting Broccoli, which is highly recommended by some writers because of its hardiness, was here in Lincolnshire amongst the first to succumb to the severity of the weather. Last year we had plenty of Savoy in the spring that stood the winter well, especially the Drumhead variety; this season they have all suffered alike, not one remains. Veitch's Dwarf Green Curled Kale were very good last spring, I cannot say the same of them this, they have also fared very badly. The London Rosette Colewort is the best green I know of to stand the test of severe weather. August plantings look as fresh as can be, and will give a plentiful supply for some time before Cabbages are fit for use. Prickly Spinach as usual has withstood the severe weather. All should have a good breadth of it and Coleworts. These two vegetables are always acceptable.—J. McK.

#### ROSES ON THEIR OWN ROOTS.

THE reason advanced by Mr. Luckhurst for "own root" Roses being kept in the background by nurserymen—viz., "from the large quantity of stout thoroughly developed wood that must be employed in making cuttings by the thousand, which wood could not well be obtained even in one of the largest nurseries without such a mutilation of the stock as would materially affect its value," is not quite a satisfactory one, as I will attempt to show.

First of all stout wood is not the sort which is best adapted for making into cuttings, that which is small and wiry being far more likely to grow. Secondly, those who have frames to spare for the purpose, as Mr. Luckhurst appears to have, need not wait for the wood to become thoroughly developed, but should insert the cuttings during July, or immediately the first blooms are fading, when, if the work is rightly done, every cutting will grow into a plant within a month. It is specially for those who have no glass that the practice of inserting cuttings of ripened wood is to be recommended, and to be successful with these they must be inserted during October or November, when many of the varieties will strike as freely as Gooseberry cuttings; and I think I might add that all the Perpetuals will do so if taken from a warm wall or from plants which have been well grown in pots, and consequently have their growth well ripened.

I do not consider there is any advantage in having such cuttings under glass, but rather the reverse; for whereas outside they will commence their growth in the natural growing season, under glass they are liable to make growth earlier and of an inferior quality. They should always be inserted rather deeply in the ground, and if protection is needed an inch of cocoa fibre refuse or coal ashes is quite sufficient for the purpose. The details of the operation have been so often given by myself and others in this Journal that I think it unnecessary to repeat them here; and I may say that I am delighted that the practice of growing Roses on their own roots is fast coming into favour even with those who grow for exhibition, and that if the past winter has made us uncomfortable in many respects, it will have the good effect of sweeping away a few more of the remaining parasites, and especially the mop-headed ones.

I cannot agree that propagating by means of cuttings is in any way a slower process than by grafts or buds when once we have a fair stock of any given variety; and in the case of Teas, Noisettes, and Chinas, which for the purpose of propagation may be made into continuous growers, I should not be afraid to back cuttings for a three-years race, both as to number and quality, against any other method a professional propagator might prefer. I must think that our great goddess Fashion is responsible for keeping the best method of Rose cultivation in the background;

it has been in this wise for a number of years, when the standards had it all their own way notwithstanding all that was said against them both by poets and prose writers. Of course nobody could wait to grow standards on their own roots, and ready-made stilts were found for them in the hedgerows; then somebody thought that an odd dwarf here and there was admissible. But as budding and grafting had become established customs there was no thought of doing away with the standards even when dwarfs were employed, especially as ladies and gentlemen had learned to bud, and although it was somewhat clumsily done it was considered an accomplishment. Nurserymen of course benefited by the delusion (as they still do by others I could name, and are not to be blamed for it), for the average age of a worked plant is only three years, and own-roots plants live long, while those among amateurs who bud the most, from some reason not very clear to me, also buy the most.

When we heard of amateurs during the good times of a few years ago spending annually from £30 to £100 on Roses, we could but rejoice at their prosperity as well as their enthusiasm for the queen of flowers. But all hobbies, whether of the animal or vegetable world, are liable to be ridden to death, and the Rose hobby is no exception. The standard has gone I hope for ever; many of its admirers are silenced through misfortune and disappointment, while those who only moved along slowly still hold their ground, and their enjoyment, if not quite so emotional as that of their fast-going brethren, is undiminished and will continue. I would say to those who have lost most of their stock, and will probably when they know their full loss think seriously of giving up Rose-growing altogether, to take courage and a lesson from some of their less ambitious brethren, and they will find the Rose still worth growing, although in one respect it is like fire and water, a good servant but a bad master.

Of all Roses to grow on their own roots Teas are the most satisfactory, because their existence depends on shoots sent up from the base while the plants are quite young, each shoot becoming stronger than its predecessor as the roots increase, and the best shoots are those produced immediately above the roots, which in the case of worked plants would be the stock. I have to-day inserted about a hundred cuttings in three varieties, which, if I have the opportunity of doing justice to, will all make flowering plants by the autumn. I no more expect that a cutting of these will fail than if they were so many Verbenas. It is of course possible they may fail from accident or neglect, but if they do it will certainly be from some cause which might have been prevented and which can be easily traced. The cuttings are formed of small shoots which have lately flowered. They are taken off mostly close to the old wood, although this is not absolutely necessary, for as long as the wood is about half ripe and the leaves are healthy they will strike very freely. They are placed firmly in boxes where there is 3 inches of sandy soil and 5 inches of space above it; they are then mounted on a couple of bricks in the path of a forcing house, heavily watered, covered with panes of glass, and made almost airtight by means of strips of paper pasted over the edges, partly on the glass and partly on the wood, and so they remain till growth commences. The three varieties are Souvenir d'un Ami, Catherine Mermet, and Devoniensis. Alba Rosea is a favourite too, but the plants of it have not been forced so early, and they are consequently not yet in condition to supply cuttings. Tea Roses two years of age are in 15-inch pots, and will flower well about the end of this month. For early forcing they must be older plants, and are best cut hard back to the ripe wood, but young plants need no pruning.—WM. TAYLOR.

#### PROLIFEROUS HYACINTHS.

HYACINTHS were better matured last season than for several years past, and this will account for their producing better blooms than usual, and may also be the cause of some of them throwing up several flower spikes. Some varieties are more prone to do this than others; but this year I have noticed it more than formerly, particularly in one of the varieties (Argus) mentioned by Mr. C. M. Major, which appears to have this property this year in a marked degree. In one collection I saw a few days ago most of the bulbs of Argus had from two to four spikes, and may therefore be said to be both "many-eyed" and "many-spiked." The seasons in Holland, like ours, are liable to variations, and when the spring is cold and backward the bulbs suffer in consequence. Should this be the case during the last year of their preparation they cannot be expected to produce spikes of bloom so good as when ripened during favourable seasons.

I noticed last year when the bulbs arrived that they were very fine, and appeared to have been well matured, and I anticipated that the spikes they would produce with careful treatment would

excel those of several years past. With reference to the second part of "C. M.'s" remarks as to the reason why the bulbs do not produce as fine blooms the second season; he will readily understand the cause of this when he is informed that before we receive them they have been specially cultivated for several years, during which period they are not allowed to bloom. After flowering once the strength that has taken years to put in the bulb is exhausted. When we consider the size of the blooms produced we do not wonder that the bulbs are comparatively worthless for another season.—J. H. S.

#### NOTES ON BOILERS.

MR. STEPHEN CASTLE'S questions (page 172) open up a wide field for discussion, as scores of people can give evidence in favour of, or against, any boiler ever invented, or any arrangement of pipes or size of mains. I would first call his and others' attention to the power of the boilers referred to. In looking over the lists of two rival makers of the Witley Court form, I find that one gives 30 inches long by 21 wide and 32 deep outside, as being capable of heating 1600 feet of piping, while the other says 800 feet only. These discrepancies in describing the power of a boiler lead to the larger portion of the failures often described, and also explain the contrary experiences of those who have the good fortune to have boilers supplied them to work the smaller quantity, or rather have had a much larger boiler to work the piping referred to by others in their correspondence. In Wright's, as in other special boilers made by one firm only, they are careful to give a much lower calculated power, so as to ensure the success of their particular patent.

As to the general question of depth of stokehole and economy whether in first cost or after consumption of fuel, I do not believe there is much difference; but neither of them can compare for speed in getting up heat with other forms where the hot water passes direct into the flow pipe without travelling over half the boiler to find an outlet and forcing before it a quantity of cool water equal to many feet of piping. All flow pipes should rise from the boiler without any dip whatever, even if only one house is to be heated. A boiler close to its work is the best, as the first 20 feet in length of pipe must of course be the hottest and give off its heat somewhere. A 2-inch main having only one-fourth the water contents of a 4-inch is necessarily hotter and quicker in imparting its heat, being also of thinner metal, but it cools more quickly for the same reasons. Four pipes must give more heat than three placed in similar position, as the heat given off depends mostly on the larger area exposed; the water inside one flow would be a little hotter naturally than in two flows.

As to dampers, they are of great use in a chimney, as the fire heat will rush up the chimney if left open whether there be a supply of air at ashpit or not, especially in frosty weather. I should fancy Mr. Castle's failure to keep his fires going more than five hours is due to having the damper too far out, as the fire will inevitably die out if no supply of air to it and the other outlet wide open. It is simply a question of good stoking and keeping sides of boiler clean, so that the fire can act upon it, as a quarter of an inch of hard caked soot is about equal in resisting heat to that thickness of iron.—B. W. WARHURST.

#### CULTURE OF THE COCKSCOMB.

THE Cockscumb is a very useful summer decorative plant, but it is not often seen in good condition. The first consideration is to procure a good strain, those having good crested flower heads being the best, although many prefer large ones, but they are often coarse. It does not require a hot-water-heated structure to grow them, as they will thrive best in a dung frame. The seed should be sown at the present time in a light compost. When the young plants obtained are large enough to handle pot them off singly into small 60's, plunge in the frame, and keep them close to the glass till they show their flower heads, when the plants may be potted into 48's, using a little decayed cow dung with the compost. Keep the frame at a good heat and plunge the pots. Continue shifting till the plants are in 16-size pots. As the flower heads reach maturity ventilate more freely. They only ought to be 15 inches from the rim of the pot to the top of the comb, which may range from 24 to 30 inches across. I have heard of larger, but have never grown them.—A FLORIST.

TO PREVENT THE GOOSEBERRY CATERPILLAR.—Boil some white hellebore powder in water and place it in a tub or garden engine, adding sufficient boiling water to syringe all the trees; when it is cold apply it on a dry day, to dry on the leaves as soon as the trees are in leaf immediately after blooming, and before

the fruit has grown. One application is sufficient for the season, and does not injure the fruit. One pound of white hellebore powder is enough for sixty trees, and is best applied with a hand syringe. I have tried this plan for years and found it to answer.—S. M. DIGGLES.

#### HARDY PLANTS AT DRUMLANRIG.

"PEREGRINE," who is better known to gardeners as a peddler in satirical observations than as a trustworthy dispenser of useful knowledge, has some savoury remarks in a contemporary on my recent notes in these pages. The clever cynic cannot conceive how I could tell the condition of his fondlings "under 6 inches of snow." This is the pith of his "joke," and at the risk of robbing it of any of its splendour I must give plain facts against "wild imaginings." As I stated before, "6 inches of snow and the thermometer about zero" were experienced on the journey to Scotland, but where is it recorded that there was "6 inches of snow on the herbaceous border" at Drumlarnrig? No doubt it would have been agreeable to "PEREGRINE'S" purpose if a covering of snow had concealed the subjects of his never-failing theme from exposing their shortcomings, but unfortunately for him and them nothing of the kind was there. Disappointing this will no doubt be to such an acute critic as "PEREGRINE;" but as he evidently has a strong ambition to be prominently identified with the subject, let me suggest a few headings under which he might advantageously employ his talents. 1st, How is it that if we want to see hardy plants cultivated to perfection, and valued and appreciated to their full worth, we must go to the gardens of those who have least to say about them? 2nd, Is it fair for any writer who does not even possess a presentable collection of hardy plants to taunt men who *do* possess complete collections and grow them well, about their want of knowledge of those plants and sympathy respecting them? 3rd, Under what dispensation has one or two gardeners been endowed with all the knowledge in the world belonging to their calling, and the multitude left without the common faculties of seeing, hearing, feeling, or understanding? Vain "PEREGRINE!" —PARAGON.

#### NOTES FROM MY GARDEN IN 1880.

##### AURICULAS.

IF in recording my experience with the Gladiolus last year I could throw up my cap and shout "ooray!" I must alter my song when I come to think over my Auriculas, and say "All round my hat I wear the green willow" in the words of a ditty I remember in years long ago; for so unsuccessful have I been, although I have grown them for forty years, that I have almost made up my mind to abandon their culture. I had no difficulty in growing them until the invasion of this abominable pest the woolly aphis, and it seems rather too hard that a little thing like this should upset one's culture of a favourite flower.

The history of this pest is a curious one, but there is no need of entering at length into it. Now it was apparently unknown until a few years ago, although I have been assured by a grower that he remembers it forty years ago, but had never heard of it since until a few years ago. When it first appeared it was spoken of as a pest which affected the plants most injuriously, that they had a very distressed appearance; but then very few persons had it in their collections. When I made my complaint about it I was assured that it was nothing of much consequence, that I could easily get rid of it; and when I stated that I found it not only on the Auriculas, but as far as I could see on even the Lettuces and Sowthistle, I was calmly told by Mr. Douglas that if a person had Sowthistles in his garden he could not expect to grow florists' flowers. Pretty well from a head gardener who has a liberal master and gives him plenty of hands; but at that time Mr. Llewelyn was suffering much in the same way in Wales, and brought up some specimens of the aphis. Various remedies were suggested—tobacco powder, sulphur, and paraffin; but will not this latter especially kill the plants? Of course you may kill anything by injudicious application; but when talking over it with Mr. Llewelyn in the presence of Dr. Hogg, Mr. L. said, so far from its injuring the plants he thought they rather liked it. The Dr. said he could quite understand that, as it acted as a manure to the plants, giving some of those constituents that they require; but no application seemed to be successful. Whether it is that any insects remain in the crevices of the roots or the stem of the plant, or whether it is another incursion from without, I know not; but they came again, and no washing or anything else seems to avail. Then came a change over the spirit of the dream. It was found that there was not a collection in the kingdom that had not got it, some more, and others in a slight degree. One most successful grower who would not buy in any plants, and would not even go to an

exhibition for fear of bringing it back with him, wrote to me and said he had found it not only in his Auriculas but in his garden, and that he did not intend to send out a plant until he had got rid of it. Another grower near at hand has been greatly troubled with it, and in all directions the same tale is told. But now we are assured it does no harm, that it may be left unmolested and the plants no way suffer. I cannot credit this, although I think that in Alpines and strong growers amongst show varieties there may be enough roots both to supply the plant with nourishment and also to feed the aphids; but I can never believe that an insect like this can suck the juices of the roots, which it is provided with means of doing, and yet do no injury. The result of it all, as far as my experience goes, is that it has in some way or other quite blasted my hopes, and that I have been so unable to overcome any difficulties that I am seriously contemplating giving up Auriculas. I have been sneered at, my inability to exhibit ridiculed, and this has been one of the unpleasant things connected with my failure. I had before thought that amongst lovers of flowers there was a kindly feeling that misfortune would only bring out, but there are exceptions, I suppose, to every rule. I have, however, to thank some kind friends for proffered help, which, however, I have for the present declined. It is pitiable to receive good plants and then see them become "small by degrees and beautifully less;" and so until I can feel that I have turned the corner I must content myself with the few I have left.

I am going this year to adopt an heroic measure. I shall place my frames, as I usually do, facing the north for the summer months. These frames I shall fill up with rough drainage more than half way up; on this I shall place a few inches of good friable loam without any manure. I shall then shake out the plants, wash the roots thoroughly, and plant them out in the frames. They shall have during the summer all gentle rains, being only covered during severe downpours, and then I shall see what the result will be. I have two very good authorities on my side in attempting this plan—Mr. Llewelyn of Penllergare, and Mr. Woodhead of Shibden Head. The former already adopts the plan of planting out and has found it to answer very well, and says that they can be lifted up from the frames and exhibited without any loss.

It will easily be seen, then, that I have but little to say upon new varieties as far as my own collection is concerned, for I have not ventured to run the risk of endeavouring to procure any; but I believe that we may soon expect to have some fine ones brought before us. Especially do I anticipate that Mr. Woodhead will produce some fine sorts; his system of hybridisation seemed to be so thorough that it ought to insure success. As yet the numbers added to our catalogues within the last few years has been small; and both those who only care for them on the home stage or those who exhibit are still dependant of those older varieties which date back twenty, thirty, or many more years.—D., Deal.

#### WINTER-BLOOMING PELARGONIUMS.

CHARLES SCHWIND is, I think, without doubt the best all-round winter-blooming variety we have. Much attention has been called to Guillaume Mangilli, a most excellent variety for summer blooming, and winter also in a warm house; but I think it is quite possible some disappointment may ensue with respect to this variety, if, as is quite probable, some of your readers infer from what was said that it has some special winter-blooming qualities (surpassing in that respect other varieties), and that it may be cultivated with success in winter in ordinary greenhouse temperature. Now this is certainly not the case. In a house maintained at a temperature of about 10° above that of an ordinary greenhouse it succeeds, but then which of the tribe does not under such circumstances? They are all nearly equally good in this respect. Under suitable cultivation they may be had in bloom in December and January, not with meagre trusses, but as gorgeous as those of May and June, the colours of the light varieties and some of the crimsons being absolutely preferable to those of summer. There is a great difference of shade in many of them in the two seasons; the whites are far purer, and some of the crimsons exquisite in winter. But are there any varieties which can be relied on to do fairly well in an ordinary greenhouse? and this is the real purport of this letter.

I will give my experience of the past season. For the first time for many years (through the failure of a boiler in the autumn), I have been compelled to let them take their chance this winter in what was practically an unheated house until Christmas, as until then no means of heating existed, except two oil stoves used only just barely to keep out frost, and even under these adverse circumstances Charles Schwind bloomed excellently. It was far away in the first position. Lizzie Brooks and Titania

(Denny), did well; an old variety, Colonel Holden, also was good, and so was an old double variety Emily Laxton. In this company Guillaume Mangilli was simply nowhere. In the low temperature it refused to open its blooms at all. I think, therefore, it would be well to caution any of your readers who may, perhaps, have gathered an impression that it is good in an ordinary greenhouse against expecting too much from it.

In conclusion I will name two or three of the newer varieties which appear likely to be excellent for winter blooming. They flowered well with me far into the winter, and this on plants not specially prepared for winter blooming, which they always ought to be by previous summer disbudding and proper culture. These are Sophia Birkin, Lizard, and Aida. The last named had some exquisite flowers to the end of December. These three are light varieties each distinct, whilst in the deluge of scarlets and crimsons we are getting too large a proportion of, to borrow Mr. Paul's phrase as applied to Roses, "the too much alike."—C., Amwell.

THE meeting of the ROYAL HORTICULTURAL SOCIETY on Tuesday next promises to be one of great interest and attraction. Messrs. Veitch's Hyacinths have never been finer than they are this year, and a splendid group will be staged. We have seen the plants at the Coombe Wood Nursery, and they will be in their best condition at the meeting. Other plants including Amaryllises from Chelsea will add to the richness of the display. Messrs. Osborns' Hyacinths, we are informed, are very good, and we presume will be exhibited. Mr. Moorman, we believe, will stage a group of plants similar to the one for which he was awarded a gold medal last year. Captain Patton's Spiræas and Dielytras are, we learn, very fine this year, and he is growing a large collection of Hyacinths. These with other contributions from the leading nurserymen, and the competition for the silver eup and prizes for Hyacinths and Tulips, may be expected to produce a display worthy of extensive patronage. Expressions of regret have reached us from exhibitors that this and the Spring Show of the Royal Botanic Society do not occur during the same week, as to exhibit at both Shows will involve expense in the carriage of plants that they consider might have been avoided; besides, the same Hyacinths cannot be in the "best" condition for the two events.

— MR. CHARLEY of Ogbear Hall Gardens desires to endorse what was said on page 195 respecting VIOLET ODORATISSIMA. He obtained it last year from Mr. Cannell, planted it out in an ordinary border, and now it is producing its fine fragrant flowers in profusion. Another gardener who grows a large collection of Violets says, "Carters' elegantissima is identical with odoratissima, and both are Prince Consort, or I have not had them true."

— MR. WALTER HILL of the Brisbane Botanic Gardens has issued a pamphlet containing a LIST OF ECONOMIC AND OTHER PLANTS which are grown in that garden, a collection of which was exhibited at the Melbourne International Exhibition, 1880. The plants are arranged under their respective natural orders, with brief descriptions of their chief characteristics and properties.

— WE are desired to remind the supporters of the PELARGONIUM SOCIETY that the Executive Committee, having to resume activities, need the usual pecuniary aid of the subscriptions that are now due. And we are further desired to invite lovers of flowers who are not members of this Society to enrol themselves in the brotherhood, the liability thereto being only one guinea per annum, but, with permission to subscribe any additional amount. The Treasurer is Henry Little, Esq., Hillingdon Place, Uxbridge.

— WE have received from Messrs. Petter & Galpin Part 25 of "FAMILIAR GARDEN FLOWERS," and Part 7 of "PAXTON'S FLOWER GARDEN," continuations of those works. The former contains coloured plates of *Plumbago capensis* and *Geum pratense*, both fairly well executed and accompanied by interesting descriptions. The part of "Paxton's Flower Garden" under notice has a coloured plate of hardy Azaleas, representing the varieties Judith, Meteor, and Sylvio, the form of the flowers being well delineated, and also one showing two varieties of *Cattleya labiata*, good in form but rather deficient in colouring. In the "Gleanings and Original Memoranda" we observe that a suggestion we made some time ago has been acted upon—namely, the removal of capital letters from specific names, except where warranted by the accepted rules of nomenclature. This is a decided improvement, but there is still another needed. The authorities are given for the names of all the plants described in the old edition, whereas they are omitted from those added to the present one, which appears a singular inconsistency.

— FOR the purpose of SAVING SEED OF PRIMULAS the plan is usually adopted—and it is a safe one—of having late-sown and late-flowering plants for this object. We recently saw at Mr. Cannell's establishment at Swanley a house 100 feet long filled with Primulas, the seed of which is nearly ready for harvesting. How far the hot-water pipes affixed to the roof have contributed to this result by drying the pollen of the flowers we know not, but certainly a finer set of seed has never come under our notice. Some later plants are still flowering, which are remarkable for their vigour, and the size, purity, and richness of the flowers. Another structure is filled with Cinerarias, some of the flowers exceeding 2 inches in diameter. There is also a fine collection of double varieties, the flowers of which are just commencing to expand. A house 240 feet long and 15 wide for the purpose of growing winter-flowering Carnations, and two other large structures for Show and Fancy Pelargoniums, are being erected. Zonal Pelargoniums were as brilliant as they usually are any time between January and December. The new white variety that was certified under the name of Eureka was in splendid condition, its large white globular trusses borne on stalks a foot long.

— WE regret to learn that MR. JAMES ALEXANDER, SENR., died at Redbraes, Edinburgh, on the 12th inst. The deceased gentleman was the senior partner in the firm of Messrs. Dickson and Co., Waterloo Place, Edinburgh.

— WE have been informed of the following GARDENING APPOINTMENTS—Mr. W. Yeomans, late gardener to Mr. Smythe, Basing Park Gardens, Alton, has been appointed gardener to Robert Schwartz, Esq., Crow's Nest, Crowborough, Tunbridge Wells; Mr. David Evans, late gardener to D. Pugh, Esq., Manor-avon, Carmarthen, has been appointed gardener to Mrs. Bullar, Basset Wood, Southampton; Mr. Z. Welbourne, late gardener to C. Coombe, Esq., Cobham, Surrey, has been appointed gardener to James Blyth, Esq., Wood House, Stanstead, Essex.

— THE thirty-seventh annual Exhibition of the SCOTTISH PANSY SOCIETY will be held in the Royal Scottish Society of Arts Hall, 117, George Street, Edinburgh, on Friday 17th June. There are seventy-four classes in the schedule, all for Pansies or Violas.

— THE schedule of the READING HORTICULTURAL SOCIETY announces that the Spring Show will be held on May the 12th, and the Autumn Show on August the 18th. The usual liberal prizes are offered in the numerous classes for plants, flowers, fruit, and vegetables, but there are a few interesting additions. For instance, at the first exhibition three prizes are offered for a group of Rhododendrons to occupy a space of 12 feet by 11 feet, and the same number of prizes are offered for twelve Show and twelve

Fancy Pansies. At the other exhibition there will be classes for Dahlias in pots and collections of double Zinnia blooms.

— THE SPECIAL LECTURES delivered in the course of last year in connection with exhibitions of the ROYAL HORTICULTURAL SOCIETY were so largely attended, and proved altogether so satisfactory, that it is with much pleasure we hear that arrangements have been made for a similar series in the forthcoming season. The Tulip, the Auricula, and the Carnation appear to be already provided for, and we shall hope that means will be found for the treatment by the same process of other equally interesting subjects. The first of the series will be on the history and peculiarities of the Tulip. The lecturer will be Mr. Shirley Hibberd, who will discourse on the subject in the conservatory at 3 P.M. on Tuesday next.

— A REVISED list of arrangements for the ROYAL BOTANIC SOCIETY'S EXHIBITIONS has been issued, in which we observe the date of the second summer Show is altered from June the 22nd to July the 6th, the evening fête being fixed for June the 22nd instead of June the 15th.

### DOUBLE CINERARIAS.

ALTHOUGH it is some years since the introduction of these from Germany, they have not taken so high a position as the single forms, which is not surprising, as they are not nearly so attractive; indeed the best of the flowers were for a time after being introduced at best crumpled semi-doubles, very indefinite in colour, and having a very weedy aspect. In many of the seedlings now, though there has been a great advance, the flowers are very small, dull in colour, and not fully double. For decorative purposes the florist forms are far more telling—indeed ninety-nine out of a hundred of the doubles raised from seed are not worth growing. Still there are some really good doubles having flowers which for size, fulness, purity of colour, and distinctness are effective and enduring both on the plant and in a cut state. For the latter purpose these are superior to the singles, which do not stand long. I have grown them every year since their introduction, having fresh seed each year, and by selection have secured some with good flowers and bright colours. These will have to be perpetuated by suckers or offsets, but by saving seed of the best of the semi-doubles a number of the progeny afford double flowers, and by continuing in this lead it is likely we shall have several useful varieties. The forms I have obtained from thousands of seedlings are dark blue, large, very good; light blue, also large and fine. One of the most beautiful is white tipped with pink. Rose-coloured flowers there are in various shades, as light, deep, and mottled, also pink and mottled pink, and other colours that may be termed crimson, purple, with carmine, mauve, and magenta. A good white I have not had, but there are whites variously tipped and tinted. The double Cinerarias need only careful selection and improvement to make them as general favourites as the others.—G. P.

### THE GLADIOLUS.

ALL growers of this grand flower of course conform to the instructions contained in the cultural notes prefixed to the catalogues issued annually. These are very brief—Trench or dig deeply; manure liberally; stake duly; protect the blooms; water freely in dry seasons; and—this they do not add—await what at best is but a doubtful issue of your labours.

It is now only five years since a splendid stand of some three dozen spikes exhibited at North Berwick by an esteemed friend—alas! now no more—whose name was prominently associated with the Gladiolus, inspired me with the determination to add this to my other favourite flowers. Since then my attachment has strengthened, my stock has been gradually increasing; and now, after a season in which my losses nearly amount to all those of former years together, it has been reinforced by additions which considerably raise the aggregate and promise increased attractions. It does not require much obstinacy or Scotch "dourness" to refuse to accept one year's losses as a sufficient dissuasive when set against four years' gratifying success.

It is on all hands conceded that the Gladiolus is in many respects a mystery. Change of ground is recommended by one, and by another this is considered unnecessary. Shallower or deeper planting has in my experience, even with the same variety, appeared

to have little influence. I suspect that the cultivation of them in the same ground for seven years, referred to by "D., Deal," comes under my own cognisance. I know other cases where, for five years at least, they have been planted in the same spot with the usual varied results. My own have for four years out of five occupied the same beds, and I mean to plant in the same again. Having hitherto manured these heavily I will dig in a good quantity

last year to remove to a garden at a little distance from his former one. This ground had for years in succession been planted with Potatoes. It was treated by him in the usual way. Losses of course occurred, but more uniform large-sized corms than those we were inspecting the other evening were surely never lifted. This is more to be observed, as I find smaller roots to be the rule this year, judging from those procured from different houses.

I fancy that my plants showed an equal average strength to his, but with few exceptions I obtained much smaller corms.

The ordinary vagaries of the Gladiolus are numerous. I have put fine healthy-looking roots into the soil, and after the others were a foot high have found these lying as planted, not a rootlet formed, and persistently refusing to grow under any treatment. As a contrast take the following. I saw a root of Lulli cast aside as hopelessly diseased; to my eyes it seemed quite useless. An acquaintance, more by way of joke than anything else, planted it. I saw a fine spike last autumn from that same corm; there could be no mistake, as such a variety was not in the possession of my friend previously. Again, out of six plants of Shakespeare growing in the same line, one, certainly not more promising than the others, produced a spike that for texture and colouring surprised all that saw it. One plant out of several of Horace Vernet cast with my neighbour a spike such as I have never seen, except, perhaps, one of my own three years ago. I had only one plant of Le Vesuve last year, and had I known nothing of the variety but from my own blotchy ill-set flower I certainly never would have had another. With my friend it was in every way magnificent; therefore I have added another root or two of that. Were Henry XIV. in reality the ragged ill-conditioned fellow he showed himself on his first appearance here he would be quite unworthy of the society in which he found himself; but we know that the disguise was but assumed. Some of my finest plants, after producing such flowers as live in one's memory, ended in that grand flare-up and—extinction. Of Meyerbeer, which never kept sound with me before, I lost only one root; and of Ondine, the most fickle of the fair, not one; and so on.

Of Mr. Kelway's varieties I have hitherto had only about a dozen. These have conducted themselves with me in much the same way as the others. Last year Brennus, Ball of Fire, Dr. Hogg, Pictum did well, and my friend had Lassia really splendid. I have added considerably to the number of my varieties of Mr. Kelway's raising, and I owe him thanks. No, they are already tendered, for something more than for the excellent corms of those obtained directly from himself.

I may be wrong, but the quality of the roots appears to depend a good deal on the quarter from which they are obtained. I know at least that those I get from two sources of supply are invariably superior to those procured from some others: I refer more particularly to houses supplying the French varieties. We have not here seen the newer additions from the Continent mentioned by "D., Deal," in his interesting paper (by-the-by, African is, as he knows, Souchet's, not Kelway's); but if these are decided advances on such varieties as Brongniart, Camille, Daubenton, De Mirbel, Mons. Legouv  , Murillo, Ondine, Orpheus, Phoenix, Psyche, and many others, they must be good indeed. Whether these must bow in deference to H.R.H. the Duchess and her train of lords, ladies, and other magnates from Mr. Kelway's collection will, I hope, in due time be seen.

Meantime, with snow lying at a depth of nearly a foot all round and still falling heavily, with roads drifted up so as to be in many parts impassable, and with every appearance of a continuance of the storm, there is as yet little prospect of furthering acquaintance with these or their less distinguished attendants;

and so we must c'en rest a little longer, inspecting the roots, consulting catalogues, and imagining forthcoming beauties during the season. May imagination end in reality, and the season be a favourable one.—A NORTHERN AMATEUR.

MANY of the newer-raised seedlings are said to be very tender,

Fig. 49. (See page 213.)

of leaf soil, which I have before now found beneficial. I shall, however, of necessity bring in another bed in ground not hitherto occupied by Gladioli, and shall observe the issue. I may adduce what seems to be in favour of a change of ground, the case of a neighbouring amateur, an enthusiastic admirer and most successful grower of these unrivalled flowers. Circumstances caused him

liable to degenerate, and capricious in flowering. The price of new certificated hybrids, however, places them beyond the reach of most amateurs. Take Mr. Kelway's, for instance. Of those of last year the cheapest, the Countess of Craven or Maid of Orleans, is half a guinea going up to 50s., the price of Samuel Jennings. Leaving such out of consideration when recommending Gladiolus culture generally, permit me to state the system that for years has enabled me to increase my limited stock considerably, and that gives me at all times and in every season fine spikes. As this is the planting season, as no garden should be without Gladioli, and as "D., Deal's," excellent notes were principally retrospective, I may not inappropriately do this, and for brevity under the following heads—

**Soil.**—The soil should be free, well pulverised, and tolerably rich. If not so, trench and dig in manure in autumn. The ground need not be left idle, as any surface-rooting hardy annual will do no harm and look well. The manure should be buried shallower than usual, as the winter rains would otherwise carry the better parts beyond the reach of the feeding roots.
